CERTIFICATE OF AUTHENTICITY

This microfilm was created from the record copy of unit histories and related historical material of the United States Air Force stored in the Archives Branch of The Albert F. Simpson Historical Research Center at Maxwell AFB, Alabama. This facility is the official repository for these records in accordance with AF Regulation 210-3 and AF Manual 12-50. This microfilm was created in accordance with the provisions of AF Regulation 12-40 as AU Project AU-1B-67. The microfilming was completed under AF Contract F01600-71-C-0478 under the supervision of the Technical Systems Branch of The Albert F. Simpson Historical Research Center.

1. General Situation: AGGRESSOR established bases in the CARIBBEAN in the fall of 1946 and since that time has launched several attacks against the UNITED STATES with varying degrees of success. The tempo of AGGRESSOR air missions over the FLORIDA Peninsula and the southeastern areas of the UNITED STATES has been increased. On 1 February 1950, AGGRESSOR dropped powerful bombs on JACKSONVILLE and MIAMI. Following this, leaflets were dropped on all principal cities of FLORIDA announcing a forthcoming invasion and threatening that any resistance or demolition of military installations would result in further retaliatory action. Beginning 2 February 1950, AGGRESSOR 1st Airborne Corps assaulted centeral FLORIDA, secured airfields, and moved northward to contact UNITED STATES Forces. Between 5 and 15 February, AGGRESSOR landed one rifle corps (two rifle divisions and one tank division) to relieve the 1st Airborne Corps which was then assembled at principal airfields in central FLORIDA, with the Corps Headquarters at ORLANDO. By the end of February, AGGRESSOR consolidated the general line JACKSONVILLE-TALLAHASSEE-APALACHICOLA. On 10 March 1950, an AGGRESSOR submarine assault resulted in the capture of WILMINGTON, NORTH CAROLINA. At the same time AGGRESSOR seized the FORT BRAGG-CAMP MACKALL-FAYETTEVILLE area by air assault, and is now enlarging and expanding his airhead.

a. Enemy Forces: (See Annex C, Intelligence)

(1) AGGRESSOR 1st Airborne Corps occupies the airhead in the FORT BRAGG-CAMP MACKALL-FAYETTEVILLE area. This corps constitutes the only known AGGRESSOR Airborne troops in the Theater.

(2) AGGRESSOR has sufficient aircraft to support a corps airhead.

(3) AGGRESSOR Capabilities:

(a) Air transporting 21,504 troops with equipment, or5,040 tons of materiel, a combat radius of 850 nautical miles from advance bases in the ORLANDO area.

(b) Conducting daily photographic reconnaissance a distance of 250 miles inland from the NORTH CAROLINA coast.

b. Friendly Forces:

(1) The Southeastern Theater (SET), with Headquarters in ATLANTA, GEORGIA, is responsible for the security of the southeastern UNITED STATES. Operating under SET, the Third Army is charged with security of the area: FLORIDA, GEORGIA, ALABAMA, MISSISSIPPI, SOUTH CAROLINA, NORTH CAROLINA, and TENNESSEE.

(2) The Third Army, composed of the V, X, XI and XII Corps, has the mission of defending the Gulf coast from the MISSISSIPPI-LOUISIANA Boundary to ELIZABETH CITY, NORTH CAROLINA.

(3) V Corps is charged with the destruction of AGGRESSOR units in NORTH CAROLINA. To accomplish the destruction of these AGGRESSOR units, an airborne operation will be conducted in the FORT BRAGG-FAYETTEVILLE-CAMP MACKALL-POPE AIR FORCE BASE area. Due to extended frontages of the UNITED STATES Forces containing AGGRESSOR in this area, the forces under V Corps must be reinforced and supplied indefinitely by air. For this operation, V Corps will be composed of the 82d Airborne Division, the 11th Airborne Division, and the 3d Infantry Division, (CPX).

(4) Carolina Base Section provides administrative and logistical support for V Corps; operates the required aerial ports of embarkation and debarkation during during build-up of the airhead; calls forward and transports troops and materiel of TFAF and V Corps through the departure and airhead bases.

c. Assumptions: Omitted.

2. Missions:

a. This force will:

(1) Conduct troop carrier, and other combat air operations, consisting of counter-air, interdiction, tactical and photographic reconnaissance, close support, and air defense in order to:

(a) Gain and Maintain air superiority.

(b) Interdict AGGRESSOR movement in the FORT BRAGG-FAYETTEVILLE-CAMP MACKALL-POPE AIR FORCE BASE area.

(c) Furnish necessary airlift for such paradrop, aerial resupply, and air landing missions required to establish and supply a corps-size airhead.

(d) Provide the tactical air support required for consolidation and expansion of the airhead.

3. Tasks for Subordinate Units:

a. Troop Carrier Force MAXTON AIRBASE, NC will provide the airlift necessary to initiate a corps-size airhead on D-Day and accomplish the subsequent airhead build-up from D-Day through D+10.

(1) The 314th Troop Carrier Wing will:

(a) Move to MAXTON AIRBASE, NORTH CAROLINA, with the 314th and the 316th Troop Carrier Groups and necessary supporting elements of the wing.

(b) Set up and operate a base operations office at MAXTON AIRBASE in accordance with AFR 20-47.

(c) Airlift personnel and equipment as directed by Headquarters, Troop Carrier Force.

(d) Stage an airborne operation on D-Day from designated bases; air drop and air land regimental combat teams in the objective area as directed by Headquarters, Troop Carrier Force.

(e) Accomplish resupply missions as directed by Headquarters, Troop Carrier Force after establishing the airhead.

(f) Accomplish evacuation missions as directed by Headquarters, Troop Carrier Force.

(2) The 62d Troop Carrier Wing (1 Squadron) will:

(a) Move one (1) Troop Carrier Squadron, with necessary supporting elements, to SHAW AIR FORCE BASE, S.C.

(b) Airlift personnel and equipment as directed by Headquarters, Troop Carrier Force.

(c) Accomplish evacuation missions as directed by Headquarters, Troop Carrier Force.

(3) The Military Air Transport Service will:

(a) Furnish one hundred (100) C-54 aircraft to arrive at CONGAREE AIRBASE, SOUTH CAROLINA, by 23 April 1950 to airlift personnel, supplies, and equipment as directed by the Commanding Officer, Troop Carrier Force.

b. The Tactical Bomber Force (2 Squadrons B-45's) at LANGLEY AIR FORCE BASE, VA, will execute counter-air and interdiction missions as directed by Headquarters, Task Force Air Force.

0009

c. The Tactical Air Force (Prov), OUTER CAMP MACKALL, N. C., will conduct combat air operations, consisting of counter-air, interdiction, close support, air defense, and support of troop carrier operations.

(1) The 4th Fighter-Interceptor Wing, LANGLEY AIR FORCE BASE, VA., will:

(a) Move the 4th Fighter Group (3 Squadrons F-86 aircraft) with minimum essential supporting elements, from LANGLEY AIR FORCE BASE, VA., to MAXTON AIRBASE, NC, so as to be operational at MAXTON AIRBASE not later than 15 April 1950.

(b) Executecounter-air, close support and air defense missions as directed by Headquarters, Tactical Air Force (Prov).

(2) The 20th Fighter-Bomber Wing (3 Squadrons F-84 aircraft) at SHAW AIR FORCE BASE, SOUTH CAROLINA, will:

(a) Execute counter-air, air defense, interdiction, and close support missions as directed by Headquarters, Tactical Air Force (Prov).

(3) The 502d Tactical Control Group will:

(a) Provide such aircraft control and warning facilities as may be required at the Tactical Air Force CP OUTER CAMP MACKALL, NORTH CAROLINA, and in the vicinity of the maneuver area during the exercise as directed by the Commanding General, Tactical Air Force (Prov), (See Annex F, Communications.)

(b) Provide necessary units (TACP's) to accompany the airborne force to the objective area.

(4) The 934th Signal Battalion (Sep) TAC will:

(a) Provide such terminal communications facilities for Headquarters, TFAF, TAF (Prov) and supporting elements, as may be required at the CP in the OUTER CAMP MACKALL area.

(5) The 4th Liaison Flight will:

(a) Move to maneuver bases as directed by the Maneuver Commander.

(b) Provide necessary aircraft for the accomplishment of administrative flights as directed by Headquarters, Tactical Air Force (Prov).

d. The 161st Tactical Reconnaissance Squadron (1 Squadron RF-80 aircraft) at SHAW AIR FORCE BASE, SOUTH CAROLINA will:

(1) Execute reconnaissance (visual and photographic) missions as directed by Headquarters, Task Force Air Force.

e. Dets., 1850th AACS Mobile Comm Sq, will furnish tower and communications service as directed by Headquarters, Task Force Air Force.

f. Dets., 2060th Mobile Weather Sq. will furnish weather service as directed by Headquarters, Task Force Air Force

x. (1) Commanding Officers of all maneuver air bases (excluding LANGLEY AIR FORCE BASE, VA.,) will prepare base Defense Plans and forward one (1) copy to Headquarters, Task Force Air Force by 18 April 1950.

(2) All organizations will conduct unit training in preparation for participating in Exercise SWARMER prior to departure from home stations. Units operating from home stations will complete this training prior to 15 April 1950.

(3) All Air Force Units will return to home stations so as to arrive not later than 2400 hours 14 May 1950.

(4) This plan is effective for planning upon receipt, and for execution on direction from Headquarters, Task Force Air Force.

4. Administrative and Logistical Matters: See Annex I, Administrative Plan.

5. Command and Signal Matters:

a. Command. See Annex A, Task Organization and Command Relationships.

b. Signal. See Annex F, Communications.

Operation Plan
TFAF No. 3-50

ANNEX B

GENERAL CONCEPT AND SCHEME OF MANEUVER

1. Accomplishment of Tasks.

a. The mission of Task Force Air Force in Exercise SWARMER is to reconnoiter, neutralize and destroy enemy air and ground forces, and their installations, in support of the airborne assault and subsequent operations; transport the airborne troops to the objective area and provide tactical air support throughout the maneuver; conduct continuous airlift of supplies and equipment to support the airhead; gain and maintain the required degree of air superiority prior to and after the establishment of the corps airhead; and be prepared to conduct such other operations as may be directed by the Commander, Task Force SWARMER for expanding the airhead.

b. Air superiority will be mandatory on and subsequent to D-Day to afford United States troops freedom of movement. Prompt processing of air requests by the Joint Operations Center and efficient dispatching of aircraft by the Combat Operations Section are necessary to insure maximum support of the ground force troops.

c. Maneuver bases are specified in Annex A, Task Organization and Command Relationships.

2. Phases of Accomplishment.

a. Supporting Operations of Friendly Forces.

(1) See Annex C, Intelligence.

b. Preliminary Operations.

(1) Prior to 15 April 1950, Air Force units will receive suitable unit training to prepare them for their operations in Exercise SWARMER. The parent Air Force will be responsible for the conduct of this training.

(2) Movement of units will be as specified in Annex I, Administrative Plan.

(3) After arrival of the units at assigned maneuver bases, or after 15 April 1950 for units operating from home bases, Commanding General, Task Force Air Force will prescribe unit training to be conducted until 21 April 1950. (See Annex D, Air Employment Plan.)

RESTRICTED

SECRET-SWARMER-SECRET

0020

THIS PAGE IS DECLASSIFIED IAW EO 13526

c. The Assault.

(1) Commencing 15 April 1950, photo reconnaissance missions of the objective area will begin, and will continue throughout the maneuver.

(2) On 21 April 1950, Air Force units will conduct:

(a) Initial Counter Air Operations.

1 Recon, visual and photo

2 Fighter-bomber operations against enemy airfields and aircraft.

3 Fighter sweeps.

4 Tactical bomber attacks on enemy airfields, control installations, fuel storage dumps, maintenance shops, hangars, etc.

(b) Interdiction.

1 Recon, visual and photo.

2 Attacks against land lines of communications, bridges, choke points, rail marshalling yards, etc.

3 Attacks on troop movements and concentrations.

(c) Air Defense (Concurrent with all phases of operations.)

1 Controlled intercept missions.

a Air alert

b Ground alert

2 At the discretion of the Commanding General, Task Force Air Force, a predetermined portion of available fighter aircraft will be allocated for air defense throughout the maneuver. Exact allocation will depend upon the tactical situation.

3 The aircraft control and warning net will be established by the 502d Tactical Control Group, not later than 15 April 1950. This net will consist basically of standard air control and warning facilities.

(3) Commencing on or about 24 April 1950, a continuous corps airhead maneuver against AGGRESSOR will begin, in which the Task Force Air Force will conduct:

(a) Counter Air Operations.

1 Same as 2.c.(2) (a) above.

2 Continuous Combat Air Patrol (CAP) over objective area on D-Day.

3 Flak-suppression missions as required.

(b) Interdiction.

1 Same as 2.c.(2) (b) above.

(c) Ground Support.

1 Conduct such close support missions as may be directed.

(d) Airborne Operations.

1 On D-Day, the Troop Carrier Force, escorted by Tactical Air Force (Prov), will airlift four (4) Regimental Teams (RCT's) to be dropped in the objective area, and one (1) RCT to be airlanded at MACKALL AIRBASE after its capture.

2 Troop Carrier Force will provide continuous airlift for buildup of the airhead from D-Day until the end of the maneuver (Simulate an indefinite period.)

3. Development of the Objective.

a. Following the airborne assault of the objective area, and the capture of MACKALL AIRBASE, the movement of Task Force Air Force units into the airhead through D/10 will be as follows:

Hq, Task Force Air Force (Adv) (Simulated)

4th Ftr-Interceptor Wing (Simulated)

161st Tac Rcn Squadron (Simulated)

502d Tactical Control Group Detachments

b. Due to limitations of facilities, no Air Force units except TaCP's and designated elements of the 502d Tactical Control Group will actually go into the airhead. Other movement will be simulated.

4. Coordination and Command Relationship.

a. Coordination.

(1) Liaison Officers to the 82d and 11th Airborne Divisions will be supplied by the Troop Carrier Force to coordinate details for airlift of these units.

b. Command Relationships.

(1) See Annex A, Task Organization and Command Relationships.

PART I - INTELLIGENCE SUMMARY

1. Summary of Enemy Situation:

a. Reference

(1) Departments of the Air Force and Army, "Directive for Joint (Army-Air Force) Exercise FY 1950", 10 December 1949.

(2) General Plan for Training Exercise SWARMER, Hq Maneuver Commander Exercise SWARMER, dated 17 Feb 50. File C 354.

b. General

(1) A state of undeclared war exists between the UNITED STATES and AGGRESSOR. The ambition of the AGGRESSOR nation is to establish itself as the most powerful nation on earth, and then by military means, to maintain such position. To achieve these objectives, the AGGRESSOR Supreme Council early appreciated the fact that the UNITED STATES must be defeated and forced to become an AGGRESSOR satellite. Then with this war potential and resources, AGGRESSOR plans to subjugate the rest of the world. Consequently, AGGRESSOR launched his first attack against the UNITED STATES in November 1946. Subsequently, AGGRESSOR has launched several attacks against the UNITED STATES with varying success.

(2) In all of the campaigns against the UNITED STATES, AGGRESSOR forces have proved to be worthy military opponents. Their leadership has been superior. Their organization, equipment, and tactical doctrine, though distinctly foreign, have been excellent. The discipline and morale of their troops have been high. AGGRESSOR Forces have proved capable of attacking, defending, withdrawing and fighting delaying actions. In addition they have proved to be capable guerilla fighters.

(3) The AGGRESSOR Fourth Army, which has occupied AGGRESSOR CARIBBEAN bases since the fall of 1946 and launched several attacks against the SOUTHEASTERN UNITED STATES, has been replaced by the AGGRESSOR Second Army and has received training in air transportability. Selected units have received amphibious training.

(4) Early in the fall of 1949, AGGRESSOR began concentrating transport, cargo ships, tankers and auxiliary craft at the principal island ports. Increased naval craft and air force planes were reported in the CARIBBEAN area. In January the tempo of AGGRESSOR air missions over the FLORIDA PENINSULA and the SOUTH-EASTERN AREAS OF THE UNITED STATES were stepped up. On 1 February 1950 AGGRESSOR simultaneously dropped powerful bombs on JACKSONVILLE and MIAMI. Following the drop of the bombs AGGRESSOR covered all the principal cities of FLORIDA with leaflets which notified the civilian and military personnel that he intended to occupy FLORIDA and that any resistance or demolition of military installations would result in the dropping of more bombs or other retaliatory action. On 2 February 1950 AGGRESSOR dropped the First Airborne Corps in CENTRAL FLORIDA, quickly secured the airfields and then moved rapidly to the north to contact UNITED STATES Forces. On 5 February AGGRESSOR began to land a Rifle Corps consisting of two Rifle Divisions and one Tank Division minus. By 15 February this corps relieved the First Airborne Corps which was then assembled at principal airfields in CENTRAL FLORIDA with the Corps Headquarters at ORLANDO. By the end of February AGGRESSOR consolidated the general line JACKSONVILLE - TALLAHASSEE - APPALACHICOLA. Intelligence reports indicated that AGGRESSOR planned to attack in NORTH CAROLINA with the primary mission of seizing the WINSTON - SALEM industrial area. Consequently on 10 March 1950, AGGRESSOR seized WILMINGTON, N. C. by a submarine assault assisted by Fifth Columnists and clandestine agents. At the same time AGGRESSOR seized the FORT BRAGG - CAMP MACKALL - FAYETTEVILLE area by air assault. AGGRESSOR is now busily engaged in building up supplies and expanding his airhead.

(5) AGGRESSOR presently has the capabilities of:

(a) Making an airborne assault any place in SOUTHEASTERN UNITED STATES with one airborne corps.

(b) Making an amphibious assault with two divisions, any place on the GULF COAST, or on the ATLANTIC COAST as far north as JACKSONVILLE, FLORIDA.

(c) Making an assault against the SOUTHEASTERN UNITED STATES with any combination of capabilities (5) (a) and (5) (b).

(6) Intelligence reports that AGGRESSOR has a limited stock of powerful bombs. It is considered probable that these bombs will be used without warning.

(7) AGGRESSOR has a large concentration of small commercial vessels. Naval operations are limited to submarine warfare and convoy protection.

(8) AGGRESSOR has developed guided missiles and rockets to a high degree of efficiency. Any concentration of troops or supplies would be a remunerative target.

(9) It can be expected that AGGRESSOR will make full use of well trained agents and sympathizers in operations.

(10) AGGRESSOR has sufficient aircraft to establish and support a Corps airhead.

c. Ground

See paragraph 1 b above.

d. Air

(1) AGGRESSOR has a large well equipped air transport command using cargo type aircraft similar to those used by the UNITED STATES AIR FORCE.

(2) AGGRESSOR has a tactical air force formed along the lines of a modern, efficient air force. The organization of the AGGRESSOR air force is not completely clear but it is known that his tactical air organization generally consists of:

(a) Reconnaissance Regiment

(b) Fighter Regiment

(c) Ground Attack Regiment

(3) In general AGGRESSOR air formation and tactics conform with those of the UNITED STATES AIR FORCE. Equipment is both of conventional and jet type aircraft. Jet fighter-aircraft have been developed to a high degree.

e. Naval

AGGRESSOR naval operations are limited to submarine reconnaissance, submarine warfare, and transport of amphibious forces to operational area by small commercial vessels.

PART II - INTELLIGENCE PRODUCTION

Paragraphs 2, 3, 4 and 5 dealing with Essential Elements of Information, Reconnaissance, Captured Documents and Prisoners of War and Captured Materiel and Souvenirs, respectively, will be published later.

PART III AUXILIARY ACTIVITIES

6. Maps, Charts and Photographs

a. MAPS: The following maps are being prepared by AMS and will be available for Exercise SWARMER:

b. Photographs:

Photographic coverage of the maneuver area, when received by this headquarters, will be distributed to air units where applicable.

Request for aerial photographic coverage by air units will conform to the provisions of Appendix 3 to this annex, when published.

c. Distribution:

Distribution of maps, charts and photographs will be made to Air Force units by the Director of Intelligence, Task Force Air Force prior to 15 April 1950. Any subsequent requests for maps or photographs will be placed with the Director of Intelligence, Task Force Air Force.

d. Disposition:

Maps, charts, and photographs, will be returned to the Director of Intelligence, Tactical Air Force (Prov), POPE AIR FORCE BASE, FORT BRAGG, NORTH CAROLINA upon completion of this exercise.

7. SPECIAL INTELLIGENCE

(To be published later)

8. SECURITY:

During preliminary planning stages this exercise will be classified as RESTRICTED. As soon as necessary movement instructions have been issued to units, and on instructions of the Maneuver Commander, security classification will be eliminated. For the play of the exercise, however, SWARMER classifications consistent with the protection required of related documents will be used. These simulated classifications will appear on documents in addition to the classification specified above.

APPENDIX I TO ANNEX C

INTELLIGENCE REPORTS

1. REPORTS AND DISTRIBUTION

Air Force Intelligence reports for Exercise "Swarmer" will be prepared and submitted as directed in the following sub-paragraphs:

a. Spot Reports (See Tab "A")

Spot reports will be submitted during the maneuver at the instant of photography, observation, or attack. The most expeditious means of communications available, including voice relay through TACC, will be utilized.

(1) Spot Reports will be submitted during each visual reconnaissance mission. The report will be in a brief narrative form and will include the following information:

(a) Name of report (Spot)

(b) Call word of unit

(c) Where--When--What--Who

(d) Heading or direction of movement

(2) A Spot Report will be submitted following photography of an assigned target or at the moment that it is decided that photography cannot be accomplished. The report will be in brief narrative form and will include the following information:

(a) Name of report (Spot)

(b) Call word of unit

(c) Results of photography (Successful or not)

(d) If not successful, why.

(e) Observations

(3) A Spot Report will be submitted following each attack and will include the following information:

(a) Name of report (Spot)

(b) Call word of unit

(c) Target identity

(d) Type attack

(e) Estimated results

(f) Observations

RESTRICTED
SECRET-SWARMER-SECRET

b. Intelligence Flash Reports (See Tab "B")

An Intelligence Flash Report will be submitted by unit intelligence officers on each mission during the maneuver within one hour after the completion of the mission. It will also be submitted on aborted missions stating the reason for abortion. The Intelligence Flash Report will contain the following information:

(1) Operations order number

(2) Mission number and assignment

(3) Date

(4) Unit designation

(5) Results of mission (Percentage of success or failure with comment)

(6) All observations and activities, including flak, weather, and information submitted as spot reports.

(7) Losses (Personnel and/or equipment), claims and opposition encountered.

c. Mission Intelligence Report: (See Tab "C")

A Mission Intelligence Report will be submitted on each mission within twenty-four (24) hours after completion of the mission and will include the following information:

(1) Operations order number

(2) Date

(3) Unit designation

(4) Name and rank of flight leader

(5) Number and type of aircraft dispatched

(6) Mission assignments

(7) Deviation from assigned route

(8) Landing place, if other than home base

(9) Observations

(a) Troop movements, concentrations and Installations

(b) Airfields

1 Location

2 Number of aircraft

3 Type of aircraft

4 Misc (unit)

(c) Transportation

(d) Miscellaneous

1 Location

2 Heading or direction

3 Number of vehicles

4 Type of vehicles

5 Miscellaneous observations with identification of units if possible

(10) Photography

(a) Location

(b) Altitude

(c) Focal length

(d) Time

(e) Vertical or oblique

(11) Narrative of mission (To include tonnages carried by TC aircraft)

(12) AGGRESSOR opposition encountered

(a) Aircraft

1 Type of aircraft

2 Location

3 Number of aircraft

4 Unit

5 Tactics employed

(b) Flak

1 Type

2 Intensity and accuracy

3 Location

4 Approximate number

(c) Other

(13) Claims

(a) Aircraft

1 Type of aircraft

2 Location

3 Number of aircraft

4 Unit

5 Destroyed or damaged

(b) Transportation

1 Type

2 Number

3 Heading or direction

4 Location

5 Destroyed or damaged

6 Miscellaneous

(c) Other

(14) Losses

(a) Personnel

1 MIA (Missing in action)

2 KIA (Killed in action)

3 WIA (Wounded in action)

(b) Aircraft

1 Destroyed

2 Damaged (Extent)

3 Missing

(15) Remarks

(16) Signature of Intelligence Officer with time filed.

2. TRANSMISSION OF REPORTS:

a. Spot Reports will be transmitted to the TACC by the most expeditious communications facilities available. The TACC will indicate the time the report was received and deliver it to the DIO in the JOC.

b. Flash Reports will be transmitted to the DIO in the JOC by the most expeditious communications facilities available.

c. Mission Intelligence Reports will be transmitted to the DIO in the JOC by the most expeditious communications facilities available.

d. Facilities for reporting purposes may be found in Appendices IV and VI to Annex F, TFAF Operation Plan 3-50.

3. RECORDS:

An Intelligence Journal and work sheet will be maintained by the duty Intelligence Officer in the Joint Operations Center and will be retained for permanent record. See Tab "D".

APPENDIX II TO ANNEX C

CLIMATIC STUDY

EFFECTS OF WEATHER ON MILITARY OPERATIONS IN THE FORT BRAGG, NORTH CAROLINA, AREA

CONTENTS

NOTE: This document is based on past records. The information on certain weather conditions to be expected is based on the assumption that more or less average conditions will occur. Since extreme weather conditions occur only infrequently, the information presented herein is deemed accurate for planning purposes. For day-to-day forecasts of the actual time of occurrence of these conditions, and for information concerning departures from the normal during actual operations, consult the nearest Air Weather Service installation.

Operation Plan
TEAF No. 3-50

MAJOR CLIMATIC CONSIDERATIONS

In general, this area has a maritime climate, due to the influence of the large high-pressure area practically always located over the ATLANTIC OCEAN, which pours moist air over this area from that moisture source and also from the GULF OF MEXICO. The air in the lower levels is fairly humid, and moderate to high temperatures prevail at this time of year (April, May, and June). Occasionally, continental air will invade this area from the west or northwest, causing slightly lower temperatures and humidities, but this type of air does not remain for very long periods of time in this season. Some fairly cold nights may exist during the early part of April, and occasionally the temperature gets very high in the June afternoons, but, in general, the weather does not cause physical discomfort.

The ATLANTIC OCEAN lies about 96 miles to the east. From the shore westward across NORTH CAROLINA, terrain rises slightly over most of the state, then rather abruptly in the APPALACHIAN MOUNTAINS which lie in the extreme western part of the state. The coastal plain lies in the eastern portion of the state and the area around FORT BRAGG is located on slightly higher ground to the west commonly referred to as the PIEDMONT PLATEAU. Mechanical lift of air up a slope can cause extensive cloudiness, but in this particular part of the state, terrain rises very slowly and topography has little effect on weather in the area. The higher terrain to the west, though, does have the effect of drying out air which moves in from that direction, resulting in less humid conditions in this area under those conditions. To the southwest and northeast, the coastal plain is fairly flat and terrain has practically no effect on the weather. The ATLANTIC OCEAN does have a slight effect. With northeast, east or southeast winds, the moist maritime air moving directly inland from the ocean is warmed from below, and forms a low cloud deck which is occasionally accompanied by light rain or drizzle.

GENERAL WEATHER INFORMATION
CLOUDINESS
APRIL

Average number of days with certain conditions of cloudiness at each hour

Hour (IST)	01	02	03	04	05	06	07	08	09	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24
Clear skies	15	15	13	13	14	11	9	9	9	10	9	8	7	6	6	6	5	6	7	8	12	14	14	15
Ceilings ** below 500 feet	1	*	*	1	1	1	1	1	1	1	*	*	*	0	*	*	*	*	*	*	*	*	*	*
Ceilings ** 500-1,000 feet	1	1	1	1	1	1	2	2	2	2	2	1	1	1	*	*	1	1	1	1	1	1	1	1
Ceilings ** 1,000-5,000 feet	3	4	4	5	5	5	4	5	4	5	5	7	8	8	9	9	7	5	6	5	4	4	4	4

Overcast below 10,000 feet	5	5	6	7	7	7	7	7	7	7	5	5	5	5	5	5	5	4	4	5	5	5	6	6

* Occurs less than 5 days in 10 years. Six days to 15 days in 10 years considered as average of 1 day
** Base of lowest clouds covering half or more of sky

Average number of days with certain general cloudiness conditions at different times of day

	Morning	Afternoon	Night
Clear skies	10	6	15
Overcast skies (any altitude)	13	11	9
Low overcast skies (below 10,000 feet)	7	5	5
Low clouds below 1,000 feet which cover 5-tenths or more of the sky	3	1	2

It is interesting to note the rapidity with which clear conditions decrease between the hours of 0500 and 0700 LST, and increase between the hours of 2000 and 2200 LST. Clear conditions occur least frequently at 1700. Extremely low ceilings (below 500 feet) occur very infrequently, generally between the hours of 0400 and 1000 LST. These ceilings lift with daytime heating from the sun, which partially accounts for the most frequent occurrence of ceilings between 500 and 1,000 feet between the hours of 0700 and 1100 LST. As daytime heating increases, these clouds lift to between 1,000 and 5,000 feet; but, in addition, on many days even though no lower clouds are present in the early morning cloudiness of the "puffy" type begins to appear about 1000 LST and these two factors cause the maximum amount of cloudiness at this level to occur between the hours of 1100 and 1900 LST, when the sun sets; and clouds begin to dissipate with nightime cooling. During the early morning, clouds at very low levels are flat, usually in layers but during the afternoon, they are generally of the "puffy" type, although lower, flat clouds may form in precipitation areas. Low cloudiness is most often overcast in the morning hours. In the lower table, a distinction is made between overcast skies at any altitude, and overcast skies below 10,000 feet because, overcasts at very high altitudes may be very thin, while those at the lower levels are usually fairly thick and cut off practically all blue sky.

GENERAL WEATHER INFORMATION, PRECIPITATION -- April

Average precipitation (inches)	3.28
Maximum precipitation (inches)	9.21
Minimum precipitation (inches)	0.53
Maximum precipitation in a 24-hour period (inches)*	1.0-2.5
Average number of days with precipitation .01 inch or greater	7
Average number of days with thunderstorms	1

* between the limits given

Average distribution of days with precipitation:

Amount (inches)	None	Trace	(.01)	(.02-.05)	(.06-.10)	(.11-.25)
Number of days	19	4	**	1	1	2

Amount (inches)	(.26-.50)	(.51-1.0)	(1.0-2.5)
Number of days	1	1	1

** Occurs less than 5 times in 10 years

Snow did not occur in April during the last ten years. A trace of snow (less than .01 in.) was reported in a previous year. At first glance temperatures in April indicate that occasional snow might occur; however, these below-freezing temperatures normally occur only with clear skies at this time of year. All precipitation during this month is in form of rain or drizzle, and during the first part of the month, occurs as drizzle at any time of day, but in the latter part of the month occurs primarily as showers in the afternoon. Precipitation occurs a little more frequently about 1700 LST and a little less frequently at noon than at the other time of day, but these maxima and minima of occurrence are only slightly different from the occurrence at any other time of day. In ten years, freezing rain was reported once in April. Hail did not occur in the vicinity of FORT BRAGG in these ten years. On the average, a thunderstorm will occur on one day in April, and will probably occur between the hours of 1600 and 2000 LST. The occurrence of the maximum and minimum amounts of precipitation is very unusual and precipitation for the month will usually run between 2 and 5 in.

GENERAL WEATHER INFORMATION, TEMPERATURE -- April

Average temperature of month	61° F.
Highest temperature recorded in last 10 years	94° F.
Lowest daily maximum temperature recorded in last 10 years	44° F.
Average daily maximum temperature	74° F.

Operation Plan
TFAF No. 3-50

Lowest temperature recorded in last 10 years 24° F.

Highest daily minimum temperature recorded in last 10 years 66° F.

Average daily minimum temperature 48° F.

Average number of days with freezing temperature 2

Average number of days with temperatures above 90 F. 1

A general summary of the data for POPE AIR FORCE BASE, FORT BRAGG, which is given above, reveals the following information. Daily maximum temperatures will probably be between 94° F. and 44° F. the highest and lowest daily maximum temperatures on record. The majority of maximum temperatures will fall below 88° F. Daily minimum temperatures will probably be between 24° F. and 66° F., the lowest and highest daily minimum temperatures recorded. Daily minimum temperatures below freezing are quite rare. Since this month is in the transition period from winter to summer, temperatures will in general, become much warmer during the month; but the variation from day to day may be quite large. This information will be representative for the area surrounding FORT BRAGG; however, minimum temperatures in low spots may be a few degrees colder, especially in the early part of the month. Temperature at the surface is also dependent on such features of the topography as vegetation, type of soil, etc., but in general, in a zone of moderate temperatures and fairly flat terrain such as this, the temperatures throughout an area are fairly homogeneous.

GENERAL WEATHER INFORMATION VISIBILITIES -- April

Average number of hours with visibilities below certain limits

Limits	1/8 mi	1/4 mi	1/2 mi	3/4 mi	1 mi	2 1/4 mi	2 1/2 mi	6 mi
No. of hrs.	3	4	7	9	9	29	32	156

Average number of days on which visibilities occur below certain limits

Limits	1/8 mi	1/4 mi	1/2 mi	3/4 mi	1 mi	2 1/4 mi	2 1/2 mi	6 mi
No. of days	1	1	1	1	1	4	4	13

Visibilities in this area are generally good. Poorest visibility occurs about 0700 LST, the time of day used in computing the above table. Visibilities below 1 mile could be expected on 1 day in April, and may last for about 9 hours. Visibilities below 6 miles occur on about 13 days in the month, and on 4 or 5 of these days will persist throughout the day. Visibilities below 2½ miles will last all day on about 1 day during the month. The chief cause of low visibilities in this area is fog, which normally occurs shortly before, and lasts until shortly after, sunrise. Fog will occur in an intensity that limits visibility to 1 mile on only 1 day in April. It will occur in lesser intensity more frequently. Smoke and haze are occasional restrictions to visibility in the afternoon, and precipitation may somewhat restrict visibility at any time of day.

NOTE: Data used in this study were for POPE AIR FORCE BASE at FT BRAGG. Fog is a very special weather element in any area study, because its occurrence depends largely on the character of the terrain in question. It will form more frequently and more intensely in low areas, valleys, and over rivers than on fairly high, level ground. This should be considered when using the above data; however, the data presented should provide a good measuring device for frequency distribution in any case.

GENERAL WEATHER INFORMATION, SURFACE WINDS - APRIL

Data for POPE AIR FORCE BASE constitute the only available data on surface winds in this area. The data will not be too representative for the entire area as light surface winds are greatly affected by local terrain; even by such features as hills and ravines. Surface winds of higher speed, however, are more representative for the surrounding area, and thus some conclusions may be drawn as to surface winds in the area.

The prevailing surface wind in April is southwesterly, although southerly and westerly surface winds are common. Generally, easterly and southeasterly winds occur less frequently than those from the other directions. Calm conditions will occur in areas surrounding POPE AIR FORCE BASE with about the same frequency that they do at that point. The stronger winds can be expected from a south-southwesterly direction.

A more complete breakdown on surface winds at POPE AIR FORCE BASE, which is not presented here, indicated that the following information would also be representative for the area. Wind speeds of from 25 to 31 m.p.h. occur only infrequently, and are usually from a south or south-westerly direction. A wind speed of over 32 m.p.h. occurred only once in 10 years, and was from the southwest. The most frequently occurring wind is from the southwest, with a speed between 4 and 12 m.p.h. Very bad weather, with very low cloud bases or very low visibilities or both, occurs most frequently under calm conditions, but when wind is present, bad weather occurs most frequently with winds from the east or northeast having speeds between 4 and 12 m.p.h.

PERCENTAGE FREQUENCY OF SURFACE WIND BY DIRECTION

TFAF No. 3-50

RESTRICTED
SECRET-SWARMER-SECRET

G-II-9
RESTRICTED
SECRET-SWARMER-SECRET

The largest change in clear conditions occurs with a decrease between the hours of 0400 and 0600 LST and with an increase between the hours of 2000 and 2200 LST. Clear conditions occur least frequently between the hours of 1400 and 1700 LST. Extremely low ceilings (below 500 feet) occur very infrequently, generally between the hours of 0200 and 0700 LST. These ceilings lift with daytime heating from the sun, which partially accounts for the most frequent occurrence of ceilings between 500 and 1,000 feet between the hours of 0600 and 1000 LST. As daytime heating continues, these clouds lift to between 1,000 and 5,000 feet, but, in addition, on many days, even though no lower clouds are present in the early morning, cloudiness of the "puffy" type begins to appear about 1000 LST, and these two factors cause the greatest frequency of ceilings between 1,000 and 5,000 feet to occur between the hours of 1100 and 1700 LST, when cooling begins, and clouds become more broken. During the very early morning, extremely low clouds are flat, usually in layers, but shortly after sunrise become puffy, and most cloudiness in the daytime is of the "puffy" type. In areas of precipitation, lower clouds may be of the flat, layer type. Cloudiness above 5,000 feet is normally in layers, and may occur at any time of day. The sky is most often overcast with low cloudiness in the morning hours. In the lower table, a distinction is made between overcast skies at any altitude, and overcast skies below 10,000 feet because overcasts at very high altitudes may be very thin, while those at the lower levels are usually fairly thick and cut off practically all blue sky.

Operation Plan
TEAF No. 3-50

GENERAL WEATHER INFORMATION - PRECIPITATION (MAY)

Precipitation Chart for May

Average precipitation (inches)	4.19
Maximum precipitation (inches)	8.06
Minimum precipitation (inches)	0.66
Maximum precipitation in a 24-hour period (inches)*	1.0-2.5
Average number of days with precipitation .01 inch or greater	8
Average number of days with thunderstorms	1

* Between the limits given

Average distribution of days with precipitation

Amount (inches)	None	Trace	(.01)	(.02-.05)	(.06-.10)	(.11-.25)
Number of days	18	6	**	2	1	2

Amount (inches)	(.26-.50)	(.51-1.0)	(1.0-2.5)
Number of days	1	1	**

** Occurs less than 5 times in 10 years

All precipitation in the month of May occurs as rain or drizzle. Precipitation which occurs in the early morning hours is normally light rain or drizzle, but in the afternoon it is usually in the form of light or moderate showers. Precipitation occurs least frequently about noon and shortly after midnight, and most frequently about 0600 LST and 1700LST but there is no outstanding difference in the frequency of occurrence at any time of day. Thunderstorms occur on an average of 1 day in the month and will probably occur between the hours of 1600 and 1900 LST. The occurrence of the maximum and minimum amounts of precipitation is very unusual and odds are very much in favor of precipitation in the amounts of 3 to 5 inches

Operation Plan
IPAF No. 3-50

GENERAL WEATHER INFORMATION - TEMPERATURE (MAY)

Temperature Chart for May

Average temperature of month	60° F.
Highest temperature recorded in last ten years	99° F.
Lowest daily maximum temperature recorded in last ten years	52° F.
Average daily maximum temperature	82° F.
Lowest temperature recorded in last ten years	30° F.
Highest daily minimum temperature recorded in last ten years	73° F.
Average daily minimum temperature	57° F.
Average number of days with freezing temperatures	0
Average number of days with temperatures above 90° F.	5

A general summary of the data for POPE AIR FORCE BASE, FORT BRAGG, which is given above, reveals the following information. Daily maximum temperatures will probably be between 99° F. and 52° F., which are, respectively, the highest and lowest maximum daily temperatures recorded. The majority of maximum temperatures will fall below 94° F. Daily minimum temperatures will probably be between 30° F. and 73° F. as these are the lowest and highest minimum daily temperatures recorded. Daily minimum temperatures below 42° F. are rather infrequent. In general temperatures will be somewhat warmer toward the end of the month than they are at the beginning, but the effect will not be so noticeable as in April. This information will be representative for the area surrounding FORT BRAGG; however, minimum temperatures in low spots may occasionally be a few degrees colder, especially on the colder mornings. Temperature at the surface is also dependent on such features of the topography as vegetation, type of soil, etc., but, in general, in a zone of moderate temperatures and fairly flat terrain such as this, the temperatures throughout an area are fairly homogeneous.

Operation Plan
TAAF No. 3-50

GENERAL WEATHER INFORMATION - VISIBILITIES (MAY)

Visibility Chart for May

Average number of hours with visibilities below certain limits

Limits	1/8 mi.	1/4 mi.	1/2 mi.	3/4 mi.	1 mi.
Number of hours	1	3	6	7	7
Limits	2-1/4 mi.	2-1/2 mi.	6 mi.		
Number of hours	21	23	107		

Average number of days on which visibilities occur below certain limits

Limits	1/8 mi.	1/4 mi.	1/2 mi.	3/4 mi.	1 mi.
Number of days	*	1	1	1	1
Limits	2-1/4 mi.	2-1/2 mi.	6 mi.		
Number of days	3	4	12		

* Occurs on less than 5 days in 10 years. Six days to 15 days in 10 years considered average 1 day

Visibilities in this area are generally good. Poorest visibility occurs about 0600 LST, the time of day used in computing the above table. Visibilities below 1 mile could be expected on 1 day in May and may last for approximately 7 hours. Visibilities below 2 1/2 miles can be expected on 4 days in May and will occur between the hours of 0300 and 1000 LST. Visibilities below 6 miles will occur on 12days, most frequently just before, and just after, sunrise, but will remain throughout the day about twice in the month. Fog is the chief cause of low visibilities in this area and occurs most frequently around sunrise. It will occur in an intensity that limits visibility to one mile on only 1 day in May. Smoke and/or haze is an occasional restriction to visibility around midday, and precipitation will occasionally restrict visibility, especially when it occurs in the afternoon in the form of moderately heavy showers.

NOTE: Data used in this study were for POPE AIR FORCE BASE AT FORT BRAGG. Fog is a very special weather element in any area study, because its occurrence depends largely on the character of the terrain in question. It will form more frequently and more intensely in low areas, valleys, and over rivers than on fairly high, level ground. This should be considered when using the above data; however, the data presented should provide a good measuring device for frequency distribution in any case.

• GENERAL WEATHER INFORMATION - SURFACE WINDS (MAY)

Data for POPE AIR FORCE BASE constitute the only available data on surface winds in this area. The data will not be too representative for the entire area as light surface winds are greatly affected by local terrain; even by such features as hills and ravines. Surface winds of higher speeds, however, are more representative for the surrounding area, and thus some conclusions may be drawn as to surface winds in the area.

The prevailing surface wind in May is southwesterly, although southerly winds are almost as common, and westerly winds also occur frequently. Calm conditions will occur in areas surrounding POPE AIR FORCE BASE with about the same frequency that they do at that point. Stronger surface winds occur most frequently from a southwesterly direction.

Operation Plan
TFAF No. 3-50

A more complete breakdown on surface winds at POPE AIR FORCE BASE, which is not presented here, indicates that the following information would also be representative for the area. Wind speeds between 25 and 31 m.p.h. occur only rarely and are from a south or southwesterly direction when they do occur. The strongest wind reported in May was between 32 and 46 m.p.h., and came from the north-west. The most frequently occurring wind is from the south or south-west with a speed between 4 and 12 m.p.h. Very bad weather, with very low cloud bases or very low visibilities or both, occurs most frequently under calm conditions, but when wind is present bad weather occurs most frequently with winds from the southwest with speed between 4 and 12 m.p.h. and with winds from the northwest with speeds between 1 and 3 m.p.h.

PERCENTAGE FREQUENCY OF SURFACE WIND BY DIRECTION
POPE AIR FORCE BASE
MAY

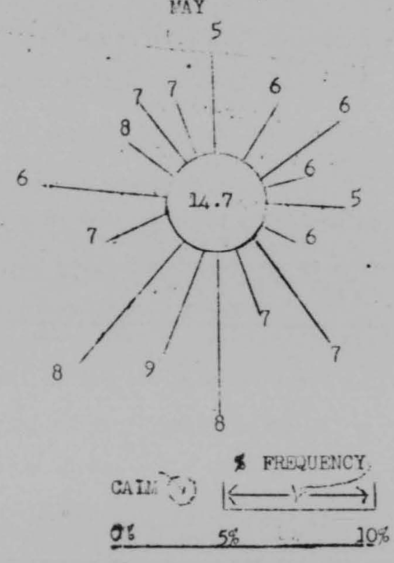

FIGURE AT END OF DIRECTION INDICATES MEAN SPEED IN MPH

Operation Plan
TFAF No. 3-50

GROUND OPERATIONS

Chemical Warfare

Criteria: Surface wind speed 4-12 m.p.h. with temperatures 32°F. to 75°F. and no precipitation (percent of time).

	April	May	June
Maximum	54.6	43.1	27.1
Mean	44.3	33.7	17.8
Minimum	25.0	17.0	7.2

The above criteria approximate those which were set up for weather requirements by the SHEAF staff for D-Day in Japan. The percentages given represent the percentage occurrence of these favorable conditions with surface winds from any direction. The length of time allotted for the preparation of this report prohibited a breakdown into the percentage occurrence with surface winds from various directions, which would possibly have been more satisfactory. In general, the conditions set forth above as favorable for chemical warfare operations vary from a possible maximum of 54.6 percent of the time in May to a possible minimum of 7.2 percent of the time in June. One conclusion which may be drawn is that favorable conditions for chemical warfare decrease in frequency through the 3-month period.

Air Ground Support

Criteria: Ceilings equal to or greater than 950 feet and visibilities equal to or greater than 3 miles 9percent of time .

	April	May	June
Mean	92.7	93.1	94.4

Favorable conditions for air-ground support exist the greater part of the time in all three months, increasing slightly in frequency of occurrence from the beginning to the end of the 3-month period. In all three months, these conditions exist most frequently in the afternoon, when they occur on all but

0055

an average 1 day per month. They are least frequent in the hours between 0600 and 0900 LST, when unfavorable conditions exist on an average 4 or 5 days per month.

Camouflage: Very little can be stated about the effect of weather on this phase of military operations during April, May and June. Snow cover does not exist in the FORT BRAGG area during that period. Many of the trees in the area are of the evergreen type and those which are not begin to leaf out, if not before the first of April, shortly thereafter. Occasionally, during April, rain prohibits planting of crops, so that cultivated areas may be without foliage until late in the month or even into May.

STORAGE OF SUPPLIES AND EQUIPMENT.

Fairly humid air exists in this region in most of April, and practically all of May and June. Most of the air which moves into this region during these three months comes from off the ATLANTIC OCEAN or the GULF OF MEXICO, both of which are excellent sources of moisture. Occasionally in April drier air will move in from the west, but later in the season this occurrence becomes less frequent. Humidity will generally be highest in the morning and lowest in the evening. Freezing temperatures occur occasionally in early April, and occasional very hot temperatures occur in June, but normally temperatures during this period are moderate.

AERIAL OPERATIONS

Paratroop Operations

Criteria: Contact conditions, i.e., ceilings 950 ft. or over and visibilities 3 miles or over, with surface winds equal to or less than 21 m.p.h. (percent of time.)

	Apr	May	Jun
Maximum	96.3	96.1	98.5
Mean	92.0	92.1	94.0
Minimum	87.5	85.7	89.2

Using the above criteria to calculate percentage frequency of available weather for paratroop operation, we find that the maximum occurrence was 98.8 percent in June and the minimum 85.7 percent in May. The mean also shows June to be the most favorable month at 94.0 percent over May and April with 92.1 percent and 92.0 percent, respectively. The percentage difference is slight, however; there is only a 2.0 percent spread, so in conclusion any or all three months should produce enough satisfactory weather for paratroop operatiions.

GLIDER OPERATIONS

Criteria: Contact conditions with wind speeds less than 31 m.p.h. (percent of time)

	Apr	May	Jun
Maximum	96.7	96.1	98.8
Mean	92.3	92.2	94.0
Minimum	87.5	86.0	89.2

A criteria of 31 m.p.h. was used, as a maximum of 30-35 m.p.h. was set up for the original weather requirments by the SHEAF staff for the D-Day operations in JAPAN. Examining the Table, we find that all three months are very favorable for this operation. Percentages range from a maximum occurrence of 98.8 percent in June to a minimum of 86.0 percent in May. The spread in the means, however, shows a range of only 1.8 percent proving all months to be well within the range of satisfactory operational weather.

AERIAL PHOTOGRAPHIC OPERATIONS

Criteria: Cloud cover equal to or less than 2-tenths with visibilities equal to or greater than 6 miles (percent of time).

	Apr	May	Jun
Maximum	45.3	40.1	33.5
Mean	36.8	33.7	26.8
Minimum	25.8	25.1	22.9

This type of operation demands the best weather possible. The requirements are so high that a much smaller operational frequency results. As the table shows, the percentages are down in the 20-45 percent range with the maximum occurrence being 45.3 percent in April and the minimum 22.9 percent in June. The mean falls off from 36.5 percent in April to 33.7 percent in May and to 28.8 percent in June. This decrease in the mean is due to the increased surface heating of the earth as the sun comes more directly overhead. This leads to higher frequency of cloud cover over 2-tenths due to greater convective activity. Thus the best month for photographic operations is April, and weather becomes progressively worse through June.

MEDIUM AND FIGHTER BOMBER OPERATIONS

Criteria: Ceilings equal to or greater than 4,500 ft. with visibilities equal to or greater than 3 miles (percent of time).

	Apr	May	Jun
Maximum	89.2	90.6	85.0
Mean	78.2	77.7	75.7
Minimum	64.0	71.5	66.0

These criteria were also used to set up requirements for D-Day in JAPAN and in lieu of any other were used to typify conditions for this particular operation. The table shows a maximum occurrence of 90.6 percent in June and a minimum of 64.0 percent in April. The mean, however, shows a slight decrease from 78.2 percent in April to 75.7 percent in June. Thus, all three months are approximately within the same range of occurrence. The increase of the ceiling requirements to 4,500 feet explains why conditions are suitable for this type of operation only approximately three-fourths of the time.

THIS PAGE IS DECLASSIFIED IAW EO 13526

Operation Plan
TFAF No. 3-50

INCENDIARY BOMBING

Criteria: Surface winds equal to or greater than 13 m.p.h. with no precipitation (percent of time).

	Apr	May	Jun
Maximum	16.3	9.2	7.8
Mean	7.2	4.0	2.3
Minimum	0.1	0.0	0.0

As incendiary bombing is not pinpoint bombing, but rather an area bombing operation, the only criteria considered were the wind and precipitation. The occurrence of the required conditions ranges from a maximum of 16.3 percent in April to a minimum of zero (0.0 percent) in May and June. The mean shows April to be the best month for this operation with a 7.2 percent occurrence, ranging downward through May with 4.0 percent and June with 2.3 percent.

FLYING WEATHER

Criteria: Contact - ceilings equal to or greater than 950 feet and visibilities equal to or greater than 3 miles. Instrument -- ceiling 451 to 950 feet with visibilities equal to or greater than 1 mile and/or visibility greater than 1 mile but less than 3 miles with ceiling equal to or greater than 451 feet. Closed -- ceiling less than 451 feet and/or visibility less than 1 mile.

The following map and table show the frequency of contact, instrument, and closed flying weather at various bases within operational distance of FORT BRAGG, N.C. These bases are representative of the remaining bases in their respective areas. Except in the northeast area contact flying weather usually occurs more than 90 percent of the time. A great deal of low cloudiness occurs in the northeast during winter. April, May, and June are transition months between winter and summer flying periods. As the flying weather is comparatively good throughout the entire area during this period, correlations between the percent of concurring contact, instrument, and closed weather at FORT BRAGG and the various airfields were not thought necessary. However, it is entirely within the capabilities of this headquarters to provide this type of data if so required. With this type of data it is possible to set up the percentage frequency of different types of military operations between a friendly field of activity and an enemy and/or other friendly fields of activity.

APPENDIX VII TO ANNEX "C"

TACTICAL STUDY OF THE TERRAIN

1. FORT BRAGG.

a. The reservation at FORT BRAGG is generally pear-shaped with the stem pointed to the east, and its center located at 79°10'31" W 35°6'31" N. The east-west axis is approximately 24.2 miles, and the north-south axis is approximately 11.9 miles at the widest part.

(1) Drainage system. JAMES CREEK flows into LITTLE RIVER and forms the northern boundary of the reservation. A ridge line extends generally through the east-west axis forming a water shed and causing streams to flow to the north and south. Numerous wet weather streams and small creeks, with an occasional lake, are distributed at regular intervals on the north and south of the water shed.

(2) There is a main ridge line extending generally through the east-west axis with numerous projections to the north and south. There is a second prominent ridge in the south-western part of the reservation. The highest elevation is approximately 500 feet, and the lowest about 150 feet.

(3) Highways and roads. Three main third class roads extend from FORT BRAGG west through the reservation: MANCHESTER ROAD along the northern boundary; LONG STREET ROAD generally through the center; and, PLANK ROAD along the southern boundary. Several dirt roads extend north and south across the reservation forming an excellent network of dry weather roads.

(4) General nature of the terrain: The terrain is generally rolling and wooded with heaviest wooded area along the streams. The highest elevation is along the southwest boundary, and center of this area. The lowest elevation is at POPE FIELD

b. (1) Avenues of approach and lines of communication: Troops can approach FORT BRAGG from any direction, The best route of approach from the west would be along the east-west ridge line.

(2) Obstacles: There are no major obstacles in the area in dry weather. All streams except LITTLE RIVER are fordable. In wet weather motorized units would experience some difficulty in traversing this area due to dirt roads and numerous stream crossings.

(3) Concealment and cover: Cover seems to be generally good with areas along streams and creeks providing the best cover.

(4) Observation: Ground observation is good.

(5) Field of fire: Generally 360 degrees of fire exist for all weapons; ideal artillery positions are sometimes difficult to find.

c. Critical terrain features: The highest elevation is along the extreme southwest boundary. RAILROAD RIDGE, JOHNSON, BLUES, GADDYS, and CCOLYCONCH MOUNTAINS are considered critical points in this area.

d. Tactical effect of terrain: The terrain is this area is such as to facilitate military operations.

e. An overlay of simulated terrain features for problem purposes will be issued later.

f. See Tab A for information on airfield at POPE AFB.

2. CAMP MACKALL.

a. CAMP MACKALL is located 7 miles southwest of FORT BRAGG reservation and is separated by a corridor approximately 6 miles wide. The camp itself has no describable shape.

(1) Drainage systems: The area is drained by three main streams; DROWNING CREEK, SWAN CREEK, and ROCKY CREEK. Numerous other small creeks and wet weather streams are distributed throughout the area.

(2) There are two prominent hills and one ridge in the northwest portion of the area. Highest elevation is about 550 feet and the lowest about 250 feet.

(3) Highways and roads: U.S. HIGHWAY 1 and the SEABOARD AIR LINE RAILWAY runs through the center of the area from north to south. STATE HIGHWAY 15 and 501 extend through the western portion of the area on a north-south line. Numerous dirt roads and trails form an excellent network of dry weather roads over the entire area.

(4) General nature of the terrain: The terrain is generally rolling and wooded. Most of the area consisted of small farms prior to the time it became a reservation.

b. (1) Avenues of approach: Troops can approach from any direction. The rolling terrain is adaptable to any troop movements.

(2) Obstacles: There are no major obstacles of note.

(3) Concealment and cover: Cover is generally good. Concealment is thin and spotty in some locations.

(4) **Observation:** Ground observation is fair

(5) Fields of fire: Generally 360 degrees of fire exist for all weapons.

c. Critical terrain features: The critical terrain features are the **SANDHILLS AREA**. The remaining terrain is of such nature as to cause it to be neither critical nor vital.

d. Tactical effect of the terrain: The terrain in this area is such as to facilitate military operations.

e. An overlay of simulated terrain features for problem purposes will be issued later

f. See Tab B for information on airfield at **CAMP MACKALL**

ANNEX D

AIR EMPLOYMENT

1. General:

a. Phases: Air operations during SWARMER are divided into phases as indicated:

(1) Phase 1 - Movement to maneuver area, 1 April 50 to 22 April 50.

(2) Phase 2 - Training, 1 April 50 to 20 April 50.

(3) Phase 3 - Air Reconnaissance, 15 April 50 to end of maneuver.

(4) Phase 4 - Air operations against Aggressor, 21 April 50 to end of maneuver.

(5) Phase 5 - Redeployment, 8 May 50 to 14 May 50.

2. Control:

a. Phase 1: Action to initiate movement of all units will be taken by SWARMER headquarters based upon schedules prepared by Task Force Air Force.

b. Phase 2:

(1) Upon arrival of units in the maneuver areas, control will be assumed by the Commanding General, Task Force Air Force, OUTER CAMP MACKALL. Units remaining at their home stations during the maneuver will come under the operational control of Task Force Air Force on 15 April 1950.

(2) Intensive unit training will be conducted upon arrival in the maneuver area until 21 April 1950 under the control of this headquarters. See Appendix II, this Annex.

c. Phase 3: Aerial Reconnaissance will be conducted against Aggressor from 15 April until the end of the maneuver. Reconnaissance missions will be as directed by JOC. See Annex D, Appendix I.

d. Phase 4: Combat air operations will be conducted against Aggressor during the period 21 April to 8 May 1950 as directed by the Commanding General, Task Force Air Force.

e. Phase 5:

(1) Movement orders will include instructions for return to home stations.

(2) Units will arrive at home stations not later than 2400 hours 14 May 1950.

RESTRICTED

SECRET-SWARMER-SECRET

3. Operations:

a. Operations in the maneuver area will be in conformance with appendices attached to this annex.

APPENDIX II TO ANNEX D

TRAINING

1. General: In order that tactical units participating in exercise SWARMER receive the maximum return for effort expended during the maneuver, it is essential that certain preliminary training objectives be attained prior to the actual maneuver (approximately 21 April 1950).

a. Ground Training:

(1) Schedules of ground training to be accomplished will be prepared by the units for implementation throughout the maneuver period, including an inclement weather schedule.

(2) Training toward fulfilling requirements prescribed by USAF, ConAC, and numbered Air Force Training Directives will be accomplished while in the maneuver area and will be included in the schedules of ground training.

(3) Ground training will emphasize the employment of tactical air power in joint operations. FM 31-35 will be used as a guide.

b. Individual Flight Training: Units will conduct individual training in accordance with existing training directives of ConAC and parent Air Forces. Each unit will submit a detailed training schedule covering the period from date of arrival in the field through 20 April 1950, to reach this headquarters not later than 1 April 1950.

c. A period of approximately six (6) days between 15 and 20 April 1950, will be utilized in conducting unit training as directed by Headquarters, Task Force Air Force, and allowance for this unit training program should be made in the training schedule. (Troop Carrier Force See Annex E). This training will include simulated counter-air, interdiction, and close support of troops. These missions will be controlled by the Joint Operations Center through the Tactical Air Control Center, and will involve coordinated air effort by all participating units. During this period emphasis will be placed on the following types of missions:

(1) Rapid take-off and assembly from dispersed positions.

(2) Offensive-defensive formation tactics.

(3) Simulated attacks against Aggressor air and ground targets.

(4) Accurate navigation and target identification.

(5) Accurate interceptions.

(6) Proficiency in escort and cover tactics.

RESTRICTED

SECRET-SWARMER-SECRET

(7) Rapid landing of group formation, emphasizing correct spacing.

(8) Correct radio control procedures and discipline.

(9) Ability to accomplish missions prescribed by the JOC.

2. Reports: See Annex K, Reports.

APPENDIX III TO ANNEX D

AIR DEFENSE

1. Responsibility: Air defense of U.S.A.F. installations and the maneuver area will be the responsibility of the Commanding General, Task Force Air Force.

a. Aircraft: Sufficient aircraft to adequately defend area will be allocated by the Commanding General, Task Force Air Force.

b. Anti-Aircraft Artillery: One gun battalion and one (1) automatic weapons battalion, AAA, will be assigned to each air base for local defense (Simulated).

2. Areas To Be Defended:

a. MACKALL AIR BASE

b. MAXTON AIR BASE

c. SHAW AIR FORCE BASE

d. LANGLEY AIR FORCE BASE

e. CONGAREE AIR BASE

f. Air Head

g. Transport Resupply Corridors.

3. Control Procedures:

a. Aircraft and Anti-Aircraft Artillery will be controlled by the Joint Operations Center through the Tactical Air Control Center.

b. Until air superiority is gained, combat air patrols will be maintained as required over SHAW, LANGLEY, CAMP MACKALL, MAXTON and CONGAREE AIR BASES. When air superiority is attained, AAA may take over the air defense of the airdromes (Simulated).

c. MAXTON and MACKALL AIR BASES will be protected from air attack by a Gun Defended Area (GDA) and an Inner Artillery Zone (IAZ) in conjunction with Combat Air Patrols (CAP). When control of the air is established, the CAP will be discontinued and defense of the Air Base, other than ground alert, will be the responsibility of the Anti-Aircraft Artillery (Simulated). The 502nd Tactical Control Group will furnish early warning radar cover and Ground Controlled Interception (GCI) from 21 April until end of the exercise.

d. The 502nd Tactical Control Group will furnish the equipment and facilities outlined in Appendix I to Annex F.

e. Flight leaders will report to the TACC at MACKALL AIR BASE upon becoming airborne on all alert missions. All aircraft, while airborne, will remain in contact with the TACC at MACKALL

RESTRICTED

SECRET-SWARMER-SECRET

0097

AIR BASE for instructions and vectors. Air defense aircraft will maintain contact with this TACC unless control is passed to a TADC or until landing time. All flights will check out with the TACC before departing the area.

4. Reporting and Relieving Procedures:

a. Radio transmission will conform to JANAP 142A, October 1949.

b. A complete list of call signs, frequencies, and channels is contained in Appendix II, Annex F.

c. On routine combat air patrol missions over MACKALL-MAXTON area, the flights will orbit the airdrome outside of the gun defended area. During the period which the objective area is being defended by Combat Air Patrols, JOC will establish the route to be flown for entrance to station. On all missions the flight commander will establish communications with the TACC as soon as possible after take off (See Appendix VII). Upon completion of mission the flight leader will contact the TACC and return to base by prescribed routes. At no time will aircraft leave the target area unless released by the TACC, except in emergency.

d. Procedures prescribed for entry into and exit from the objective area must be adhered to in order to insure proper identification.

5. Air Raid Warning Conditions:

a. Responsibility for prescribing conditions of readiness rests with the Commanding General, Tactical Air Force (Prov), who will normally exercise control through the TACC.

b. Air raid warning conditions and anti-aircraft control colors:

RADIO	MEANING
FLASH RED	Air attack imminent-enemy aircraft in vicinity.
FLASH BLUE	Air attack probable-unidentified aircraft in vicinity.
FLASH WHITE	All clear-aircraft identified as friendly.
CONTROL GREEN	All guns hold fire on air targets unless attacked or positively identified as enemy.
CONTROL YELLOW	All guns fire on any target not positively identified as friendly.

6. Readiness Conditions:

a. Aircraft assigned for the purpose of air defense and interception will be on a standby status in one of the following states of readiness:

(1) Condition One: Flight personnel in possession of latest information of the tactical situation, flight gear on, sitting in aircraft with starting units plugged in, and prepared to be airborne within five (5) minutes after scramble order is given.

(2) Condition Two: Personnel and equipment in readiness to become airborne on fifteen (15) minutes notice.

(3) Condition Three: Personnel and equipment in readiness to become airborne on thirty (30) minutes notice.

7. Anti-aircraft Coordination:

a. The Joint Operations Center will be responsible for AAA coordination in the MAXTON and OUTER CAMP MACKALL area. The Ground Force Commander will be responsible for coordination in the objective area until the TADC (Simulated) is operational.

b. The Commanding Officer of the 20th Fighter Wing will be responsible for coordination in the SHAW AFB-CONGAREE AIR BASE area.

Operation Plan
TFAF No. 3-50

APPENDIX III TO ANNEX D

AAA CONTROL AND EMPLOYMENT (SIMULATED)

1. General:

a. Deployment:

(1) Anti-aircraft artillery of the 202nd, 209th and 212th AAA Gun Battalions and the 61st, 62nd and 63rd Automatic Weapons Battalions will be deployed so as to effect maximum protection against hostile air activity at all U.S.A.F. maneuver bases. Deployment of these weapons will be as agreed upon by the Commanding Officer, AAA Group and the Commanding General, Tactical Air Force (Prov).

b. Control:

(1) In accordance with letter Headquarters, USAF, 18 August 1947, Joint Agreement Headquarters, USAF, and Headquarters, US Army, the Commanding General, Task Force Air Force, will assume operational control of AAA units committed to this exercise.

2. Operations:

a. Gun Defended Area: An area, 8,000 yards in radius, surrounding MACKALL and MAXTON AIR BASES will be designated as a gun defended area (GDA).

(1) All aircraft entering and leaving the GDA will be positively identified. To facilitate recognition, all aircraft will enter and leave the GDA by a route and altitude designated by the JOC. Aircraft not positively identified as friendly will be subject to AAA fire.

b. Inner Artillery Zone:

(1) Certain areas within the GDA may be designated as inner artillery zones (IAZ).

(2) Flying over IAZ's at any time and at any altitude is expressly forbidden. Any aircraft flying over an IAZ will be subject to AAA fire without notice.

3. Employment Procedures:

a. Control Relationship:

(1) Control of AAA fire will be effected by the TACC through the Antiaircraft Artillery Operations Room (AAOR).

(2) The TACC and AAA information service (AAAIS) will mutually exchange air raid movement information.

b. Control Conditions: Control conditions of AAA fire will be coordinated through the AAA Liaison Officer. Control conditions will be ordered as follows:

(1) Control Green. Anti-aircraft batteries hold fire.

(2) Control Yellow. Anti-aircraft batteries released for fire.

(3) When individual anti-aircraft batteries are in Control Green and under direct attack appropriate defense measures may be adopted.

APPENDIX III TO ANNEX D

NIGHT FIGHTER EMPLOYMENT PLAN (SIMULATED)

1. Mission: The Night Fighter Units participating in Exercise SWARMER will furnish airborne surveillance and defense at the SHAW, CONGAREE, MAXTON and MACKALL AIR BASES during the periods of darkness from 21 April until D/10. The TACC or TADC will furnish target information to the night fighter patrols while they are within range.

2. Control Procedures:

a. Operational control of the night fighter units will be exercised through the TACC. Aircraft under the control of the TACC or a TADC are required in all cases to follow instructions until released.

b. Aircraft clearing from stations beyond the range of TACC or TADC will contact one of these stations over the predetermined call point.

c. Night fighters will operate quadrant patrols in the general area around MAXTON and MACKALL AB's from sunset to sunrise.

d. Night fighter aircraft will not enter the Gun Defended Area which is bounded by a circle eight thousand (8,000) yards in radius around MAXTON and MACKALL area.

e. General surveillance missions will be conducted between home bases and the maneuver bases in order to harass any enemy missions which might be enroute to the defended area from outlying enemy bases.

f. The night fighter aircraft will be under the control of the TACC or TADC before entering the area and for the duration of the mission.

g. Each replacement aircraft will arrive in the patrol area five (5) minutes prior to the scheduled release time of the aircraft on patrol. No aircraft on patrol duty will return to base prior to being released by the TADC, except in emergency.

APPENDIX IV TO ANNEX D

EMERGENCY PROCEDURES

1. General: This plan prescribes emergency procedures to insure coordinated action in event of emergencies.

2. Control:

a. Paragraph 9a, AFR 20-54 provides that the Area Control Officer of Air Rescue Service is responsible for supervision and operation of rescue activities within his area.

b. Base Commanders:

(1) Commanding Officers of all bases who become cognizant of aircraft in distress will immediately notify the nearest air rescue unit, passing on all information available, such as type of aircraft, point of departure, designation, airspeed, course, altitude and last known position.

(2) All Air Force organizations are responsible for giving all assistance practicable to authorized agencies conducting search and rescue activities, when so requested.

c. Coordination to assist both of the above is essential from Tactical Air Force through the JOC and other facilities which will be available.

d. Release of Information to News Papers: Release to news media of information concerning overdue and missing aircraft will be the responsibility of the commander of the base of departure, or the officer who assumes that responsibility, except that once an aircraft has been declared missing, the commander of the Air Rescue Service activity in charge of the physical search and rescue operations is permitted to release information concerning the progress of search and rescue operations. In all cases the release of information will be in accordance with existing Air Force policies.

3. Reporting Procedures: Instructions contained herein supplement AFR 60-6.

a. Action to be taken by pilots observing an accident or aircraft in distress will be as follows:

(1) Keep aircraft in sight.

(2) Turn on automatic identification equipment, if so equipped.

(3) Report situation through Tactical Air Control System or to any agency that may be contacted.

(4) Follow instructions of TACC or TADC.

(5) Turn off automatic identification when leaving area.

b. Action taken by personnel on the ground observing an accident or aircraft in distress:

(1) Report by phone to nearest base, military installation or JOC.

(2) Describe incident.

(3) Give location.

(4) Give name, rank and AFSN.

(5) Advise of action being taken.

(6) Time of occurrence.

(7) Names of witnesses, if any.

c. Action Taken by Units:

(1) Comply with AF, ConAC, and numbered AF Regulations.

(2) Notify the JOC.

(3) Coordinate search activities with the JOC if a search is required. (This will not be cause for delay if prompt action is indicated by the circumstances).

4. Procedures: Aircraft in distress to follow one of the following procedures:

a. Aircraft Safety Procedure:

(1) When the pilot of an aircraft is uncertain of his position or is expecting a state of emergency, but with the aid of surface stations can proceed on a course, or land at a suitable air field, he will call the surface station using normal procedure.

(2) If the pilot of an aircraft is unable to contact surface stations or does not know what station to call he will use the international safety signal TTT on radiotelegraph (CW) and/or EMERGENCY for radio telephone (Voice).

(3) If the aircraft is unable to contact the ground station, the International Urgent Signals, on radiotelegraph (CW), and/or PAN on radiotelephone (Voice) will be used.

(4) After contact has been established, the pilot will transmit his emergency message which should contain the following information:

(a) Best estimated position and time thereof.

(b) Course, speed and altitude.

(c) Available flight time remaining.

(d) Intention of airplane commander as to ditching, bailing out or crash landing.

b. Aircraft Distress Procedure:

(1) When an aircraft is threatened by serious and imminent danger and requires immediate assistance, the pilot will transmit SOS on CW and/or MAYDAY on voice, giving, if time permits, the information contained in 4.a. above.

5. Aircraft Accident Reporting:

a. Preliminary accident reports will be rendered in accordance with part 3, section 1, of Air Force Regulation 62-14, dated 20 October 1944.

b. Investigating and reporting of aircraft accidents will be as prescribed in AF Regulation 62-14.

(1) In event of an accident, the Commanding General, Task Force Air Force will be notified immediately by TWX, giving all preliminary information. A complete information copy of each accident report will be forwarded to the Commanding General, Tactical Air Force (Prov).

APPENDIX V TO ANNEX D

SAFETY AND CONTROL PROCEDURES

1. General: In order to conduct operations SWARMER with a maximum of safety, certain procedures for control and safety are outlined herein.

2. Responsibility: It will be the responsibility of the unit commanders to ascertain that all pilots in their organizations are thoroughly familiar with safety precautions and procedures to be used during this maneuver.

3. Control:

a. Base Commanders will comply with current Air Force Regulations in clearing aircraft and establishing local flying areas.

b. Radar and radio control will be supplied by the 502nd Tactical Control Group for the maneuver area.

c. The maneuver area has been designated a temporary air space reservation and will be closed to all traffic not participating in the exercise, except commercial aircraft flying through the AIR TUNNEL below five thousand (5,000) feet. (See Appendix VII).

d. All aircraft will fly through the corridors extending from operating bases to the objective area.

e. Radio range facilities will be utilized in marginal weather in order to stay within the air space reservation.

4. Safety:

a. No aircraft will enter instrument weather unless properly cleared.

b. No aircraft will fly at an altitude lower than five hundred (500) feet, except when on a specific mission requiring a lower altitude, and in no case will an aircraft fly lower than two hundred (200) feet.

c. Except when flying in formation an aircraft will not approach another closer than one thousand (1,000) feet.

d. An air tunnel across the air space reservation has been established for commercial aircraft. No military aircraft will enter the tunnel below five thousand (5,000) feet altitude.

e. Aircraft flying in different directions, in the air corridors, will conform to Air Force Regulation (60-16) in reference to altitude separation.

OBJECTIVE AREA APPROACH PROCEDURES

1. All aircraft under the control of the Commanding General, Task Force Air Force will utilize the approach lanes shown on the Approach and Reference Chart SWARMER.

2. All SWARMER friendly aircraft approaching the objective area on lane A or B will call the controlling Tactical Air Control Center when over the designated reference point. Lane A, Reference Point, ROCKY MOUNT, N. C., code name TARE. Lane B, Reference Point, HARTSVILLE, S. C., code name DOG.

   a. The following information will be transmitted to the TACC by the Flight or Squadron leader of the particular aircraft involved.

      (1) Call sign of the Flight or Squadron

      (2) Altitude of flight

      (3) Number and type of aircraft

      (4) Type of mission

      (5) Estimated time in target area.

         (a) Example: "Hello, FRISCO this is STEAMER with 16 Eagles, Angels 20, Sweep, 30 minutes".

3. Support aircraft will, upon completion of their mission and after being released by the TACC, return to their base VIA approach lane, at the most economical altitude.

4. No aircraft will enter the target area until cleared by the TACC or TADC.

5. Air Coordinators, Observers and aircraft employed in special missions will make the same report as specified in Par 2.

6. Approach Sectors, Reference and Orbit Points:

   a. Reference Point TARE, (ROCKY MOUNT, N. C.), Lane A, is located at Lat 35°-55' Long 77°-48'.

   b. Reference Point DOG, (HARTSVILLE, S. C.), Lane B, is located at Lat 34°-29' Long 80°-4'.

   c. Reference Point FRISCO, is located at Lat 35°-3' Long 79°-31'. TADC is stationed at this point.

   d. Reference Point CHERRY, (MACKALL AIR BASE) is located at Lat 30°-24' Long 80°-4'.

   e. Reference Point SCARLET, (POPE AIR FORCE BASE), is located at Lat 35°-7' Long 79°-1'.

Operation Plan
TFAF No. 3-50

f. Reference Point PLUM, (MAXTON AIR BASE), is located at Lat 35°-7' Long 79°-22'.

7. The approach lanes into the objective area will be from five (5) to seven (7) miles wide, and will extend three (3) miles beyond the designated SWARMER Air Bases. (See Appendix VII).

8. Air Bases established within the objective area will be designated by the following names:

a. MACDILL AIR BASE -- CHERRY.

b. POPE AIR FORCE BASE -- SCARLET.

ANNEX E

TROOP CARRIER PLAN

1. Task Organization: All Troop Carrier and Transport aircraft participating in exercise "SWARMER" will be organized into a Troop Carrier Force. All aircraft referred to herein as Troop Carrier will include MATS aircraft. (See Annex "A", Task Organization)

2. Mission: The Troop Carrier Force will provide the airlift necessary to initiate a corps-size airhead on D-day and accomplish the subsequent airhead build-up from D thru D + 10 by accomplishing the following tasks:

a. Airlift four (4) RCT of the 82nd and 11th Airborne Divisions from MAXTON AIR BASE, N. C., SHAW AIR FORCE BASE, S.C. and CONGAREE AIR BASE, S. C. to be air dropped into the assult area in vicinity of FORT BRAGG, N. C. (See Appendix I, Airborne Planning Data)

b. Air lift one (1) RCT of the 11th Airborne Division from CAMP CAMPBELL, KY., for air landing at MACKALL AIR BASE, N. C.

c. Air lift Division troops of 82nd and 11th Airborne Divisions to MACKALL AIR BASE, N. C.

d. Air lift 3rd Infantry Division (CPX) to MACKALL AIR BASE, N.C.

e. Air lift supporting elements and service troops of V Corps to MACKALL AIR BASE, N. C.

f. Air lift TFAF elements to MACKALL AIR BASE, N. C. as follows:

(1) One (1) Fighter Wing (Simulated)

(2) One (1) Reconn. Squadron (Simulated)

(3) Control elements

(4) Service elements

RESTRICTED

SECRET-SWARMER-SECRET

g. Air lift other Army elements as required by V Corps to MACKALL AIR BASE, N. C.

h. Air lift the replacement and reserve personnel required by V Corps for expansion of airhead to MACKALL AIR BASE, N. C.

i. Air lift to MACKALL AIR BASE, N. C. the equipment and supplies necessary for TFAF, V Corps and Carolina Base Section to conduct operation in the airhead from D-day thru D+10.

3. Tasks for subordinate Units:

a. The Troop Carrier Force will:

(1) Control and operate all troop carrier aircraft participating in the maneuver, based on allocations contained in Appendix II, Aircraft Allocation Schedule.

(2) Provide Liaison Officers to the 82nd and 11th Airborne Divisions to coordinate details of airlift of those units.

(3) Provide necessary personnel to man the TFAF movements Section (See Appendix II, Annex A). This section will be located at Headquarters, TFAF and personnel will be in place by 18 April 1950.

(4) Prepare detailed schedule of missions for period D thru D+10 for all troop carrier aircraft, containing information outlined in Appendix III, Chronological Schedule of Missions Chart and submit information copies to Hq, TFAF prior to 15 April 1950

(5) Provide an Air Field Control Party to coordinate landing, parking and off-loading of all aircraft in the airhead in conformance with Appendix IV, Landing, Take-off and Parking Patterns.

(6) Provide all participating troop carrier units with detailed instructions regarding flying operations and aircraft handling in the air head.

(7) Furnish Hq TFAF by 1800 hours (EST) daily, effective 20 April, with number of aircraft by type available for the following day.

(8) Furnish Hq TFAF, prior to 1 April, with detailed schedule of training from date of arrival in the maneuver area through 20 April for all participating troop carrier units.

b. The 314th Troop Carrier Wing will:

(1) Provide the commander for the Troop Carrier Force to be located at MAXTON AIR BASE, N. C.

(2) Provide personnel for the staff of the Headquarters, Troop Carrier Force as directed by the Commanding General, Troop Carrier Force.

(3) Provide six (6) Troop Carrier Squadrons to airlift personnel, supplies and equipment for the initial airborne assault and the airhead build-up.

(4) Insure that necessary coordination between the fighter unit and troop carrier units has been achieved on the use of MAXTON AIR BASE so that both units will be able to fulfill their commitments. Maneuver Base - MAXTON AIR BASE, N. C.

c. The 62nd Troop Carrier Wing will:

(1) Provide Personnel for the staff of the Headquarters, Troop Carrier Force as directed by the Commanding General, Troop Carrier Force.

(2) Provide one (1) Troop Carrier Squadron to airlift personnel, supplies and equipment into the air head as directed by the Commanding General, Troop Carrier Force. Maneuver Base - CONGAREE AIR BASE, S. C.

d. The Military Air Transport Service will:

(1) Provide personnel for the staff of the Headquarters, Troop Carrier Force as directed by the Commanding General Troop Carrier Force.

(2) Provide one hundred (100) C-54 aircraft to airlift personnel, supplies and equipment into the air head as directed by the Commanding General, Troop Carrier Force. Maneuver Base-CONGAREE AIR BASE, S. C.

e. United States Air Force Reserve Troop Carrier Units will:

(1) Provide personnel as requested by the Commanding General Troop Carrier Force to coordinate details of Reserve airlift.

(2) Provide thirty six (36) C-46 aircraft to airlift personnel, supplies and equipment into the air head on 29-30 April and 1-2 May as directed by the Commanding General, Troop Carrier Force. Maneuver Base - SHAW AFB, S. C.

4. General Instructions:

a. All paradrop and aerial resupply missions will utilize C-82 and/or C-119 aircraft.

b. All troop carrier operations will be carried out in conformance with troop carrier SOPs.

c. The allocation of airlift by tonnages will be made by the Maneuver Commander and aircraft for the movement of personnel, supplies and equipment will be allocated by Hq. TFAF to the T Troop Carrier Force. (See Appendix V, Flow Chart of Logistical Movement Control).

d. Loading, lashing, unlashing and unloading of all supplies and equipment in and from troop carrier aircraft will be a function of the Port Companies assigned the Carolina Base Section; however, in no manner does this relieve the pilot from the responsibility for final approval of the loading and lashing in his aircraft.

ANNEX F

COMMUNICATIONS - ELECTRONICS

1. GENERAL INSTRUCTIONS.

a. Communications-Electronics systems and facilities to be established in support of Tactical Air operations, for Exercise SWARMER, will conform generally to those set forth in FM 31-35.

b. Establishment of normal Command, Administrative, and Operational nets, both wire and radio, will be in conformance with standard operating procedures of a Tactical Air Force.

c. All usage of communication-electronic equipment will be in accordance with procedures set forth in current JANAP's and CCBP's.

d. Encryption of messages will be in accordance with Traffic Security Plan as established by Headquarters Exercise SWARMER and issued as appendix to this annex.

e. All participating communications personnel will be thoroughly briefed in all phases of the air operations and the contributing communications networks.

f. Radio-telephone procedures will be in accordance with JANAP 125. Telegraph procedures will be as set forth in CCBP-1.

g. Conditions relative to safety of life or aircraft will automatically terminate restrictions imposed by maneuver regulations as to radio silence. All communication facilities will be placed at the disposal of the unit concerned to facilitate rescue operations.

h. This annex, and appendices, is effective upon receipt for planning, and effective for operations concurrently with Air Operations Plan No. 3-50, Headquarters, Task Force Air Force.

2. RADIO.

a. Task Force Air Force radio nets to be established in support of Air Force operations during Exercise SWARMER will be in accordance with Command, Administration and Operational requirements. They will consist of:

(1) Tactical Air Command, Command net:

(a) Headquarters, Tactical Air Command.

(b) Headquarters, Fourteenth Air Force.

(c) Headquarters, Tactical Air Force (Prov) Advance.

(d) Headquarters, Tactical Air Force (Prov) Rear.

RESTRICTED

SECRET - SWARMER - SECRET

(2) Task Force Air Force, Command net:

(a) Headquarters, Tactical Air Force (Prov) Advance.

(b) Headquarters, 20th Fighter Bomber Wing.

(c) Headquarters, Tactical Bomber Force.

(d) Headquarters, Troop Carrier Force.

(3) Tactical Air Force Liaison (Air Ground):

(a) Headquarters, Tactical Air Force (Prov) Advance.

(b) Commander Airborne Troops (In Flight).

(4) Tactical Air Force HF RTTY Net:

(a) Headquarters, Tactical Air Force (Prov) Advance.

(b) Headquarters, Tactical Air Command.

(5) TACC - Tactical Control Net:

(a) TACC.

(b) TADC's.

(c) TACP's.

(6) TACC - Teller Net:

(a) TACC.

(b) TADC's.

(7) For detailed outline and schematic diagrams of complete air ground, point to point net works, see Appendix V, this Annex.

b. Radio Frequency Plan.

(1) See Appendix II, this Annex.

c. Radio Call Signs.

(1) Radio call signs are contained in Appendix III, this Annex.

d. Radio Procedure and Discipline.

(1) Organization Commanders will exercise strict supervision to insure that their stations in the radio nets are operated in accordance with approved procedures to the end that traffic is cleared efficiently, accurately, and rapidly. Serious offenses against circuit discipline or repeated failure to conform to prescribed procedure, either CW or Voice, will be noted by the Umpire who will take appropriate action in each case.

(2) Joint and combined R/T procedure is set forth in JANAP 125.

3. RADAR.

a. Radar facilities will be sited and employed in accordance with applicable Technical and Field Manuals for each type Radar, and in accordance with Tactical Air Force Doctrines.

4. TACTICAL COMMUNICATIONS.

a. Tactical communications network of radio, telephone, and wire will be established as required to provide necessary inter-communications linking TACP's TADC's and TACC of the 502nd Tactical Control Group in accordance with Standard Operating Procedures of that unit.

b. Air-Ground facilities of ground control will be as required to provide necessary aircraft control.

5. NAVIGATIONAL AIDS.

a. Standard AACS navigational aids consisting of; Tower Control Communications; Ground Control Approach System; Homing Beacons; Interphone Communication Services, and Aircraft Control Communication Networks, will be provided at, and between each Air Base occupied by Task Force Air Force units. Responsibility for installation, operation and maintenance for these facilities is held by Detachments of the 1850th Mobile Communications Squadron, (AACS).

6. AIR RAID WARNING.

a. Air Raid Warning services for Headquarters, Task Force Air Force, Headquarters, United States Ground Forces, and all subordinate units within the Task Force Air Force Area of responsibility, will be the function of the JOC. Operational channels will be utilized by the JOC for air warnings as required.

7. WEATHER.

a. Weather service for Headquarters, Task Force Air Force, and all subordinate units will be the responsibility of Detachments of the 2060th Weather Squadron in accordance with Standard Air Weather Service procedures and practices for air base operations. Communications for weather services will be a function of the AACS communications facilities as provided each base.

8. INTELLIGENCE COMMUNICATIONS.

a. Communications facilities for the collection and dissemination of intelligence data will be provided through normal operational channels as furnished to the JOC under provisions of the General Communications Plan.

9. WIRE COMMUNICATIONS.

a. Radio voice tactical calls will be used to designate unit switching centrals. The words "Rear, Main, Advance, etc." may be added to designate appropriate echelons.

b. Teletype-Radio CW tactical calls will be used to designate unit headquarters.

c. Responsibility-See Appendix I, this Annex.

10. VISUAL COMMUNICATIONS.

a. All flying personnel will be thoroughly familiar with hand and other forms of visual signaling and make maximum use of same to alleviate overloading of aircraft tactical circuits.

b. CCBP-8 will be the code governing use of air panels.

11. COMMUNICATIONS FAILURE.

a. Failure in communications, whether equipment or personnel, will be reported to this command in writing stating deficiency, cause and corrective action instigated.

12. COMMUNICATIONS SECURITY.

a. Codes, Ciphers, and Crypto-Aids.

(1) Cryptographic instructions are contained in Appendix VIII, this Annex.

(2) CCBP-8 will govern the use of Air Panels.

b. Authentication.

(1) Authentication systems are contained in Appendix VIII, this Annex.

c. IFF Code Assignments.

(1) See Appendix IX, this Annex.

13. UNIT RESPONSIBILITIES.

a. See Appendix I, this Annex.

14. ELECTRONIC COUNTERMEASURES (ECM).

a. Electronic countermeasures will be controlled at the Umpire level.

b. All communications and radar activities should be alert to the possibilities of the enemy's use of electronic countermeasures.

c. Electronic countermeasures are not to be employed in a manner which will jeopardize the safety of any unit or aircraft by confusing its safe maneuver or deceiving it into a dangerous situation.

d. Electronic countermeasures are not to be employed to the extent where it will seriously confuse operating forces or impede the main objective of joint tactical and operational training. They are to be utilized only for short periods not to exceed ten (10) minutes and not more than once each hour perspecific circuit.

e. Active communications countermeasures will not be employed.

f. Neutral circuits such as Maneuver Commander, Umpire, Press, Civilian, Search and Rescue, etc. will not be subjected to electronic countermeasures.

g. Aids to air navigation such as Instrument Landing System (ILS), Ground Control Approach (GCA), Beacons, and Glide Path Frequencies will not be subjected to electronic countermeasures.

15. REFERENCE PUBLICATIONS.

a. FM 31-35.

b. TB-SIG-5.

c. TB-SIG-54.

d. AF Manual 100-25.

e. AFL-AFOIR 311.5 dated 3 mar 49, Security of Airborne Reconnaissance Operations.

f. AFL-AFQAC-311 dated 10 Feb 49, Joint Electronic Countermeasures Policy.

16. TIME.

a. Instructions relative to time are contained in JANAP's 121 and 144.

b. A date time group or time group will be used on all messages and all signal or voice radio transmission when a later reference may be required.

c. Message reference will be made by use of the originators abbreviated title plus the date-time group of the message; e.g., CGAFF 121343Z. This stipulation does not preclude the additional use of internal serial numbers if considered essential.

d. Zebra time will be used for message date time groups.

e. Local Zone time plus Zone designation applies for operations.

NOTE: In the event of an actual emergency, the Exercise Commander will send to all units "Exercise Terminated". Upon receipt of this message, each unit shall:

1. Terminate exercise conditions.

2. Place all communications in standby status, clear channels of exercise traffic and await instructions as to emergency requirements.

Operation Plan
TFAF No. 3-50

APPENDIX I TO ANNEX F

UNIT RESPONSIBILITIES

1. Specific unit communications responsibilities for the implementation of the operation plan are as follows:

a. 502nd Tactical Control Group:

(1) In the Headquarters, Tactical Air Force (Prov) Advance area:

(a) Install, maintain and operate one (1) TACC.

(2) In the MAXTON AIRBASE area:

(a) Install, maintain and Operate one (1) TADC-H.

(3) In the CANDOR area:

(a) Install, maintain and operate one (1) TADC-LW

(4) In the V Corps area MACKALL AIRBASE:

(a) Install, maintain and operate six (6) TACP's.

(5) In the SANDSTONE HILL area (FORT BRAGG):

(a) Install, maintain and operate one (1) GCI (Ground Control Intercept Station).

(6) Provide personnel and equipment to establish communication nets for ground control of aircraft and point to point inter-communications systems between TACC, TADC and TACP's. These nets will be as required to implement the tactical mission of the 502nd Tactical Control Group in providing early warning, aircraft control and facilitate tactical air operations in support of Ground Forces.

(7) Frequencies and unit call signs to be employed by the Task Force Air Force units will be published by Headquarters Exercise SWARMER and will be as indicated in Appendix II & III, this Annex.

b. The 934th Signal Bn (Sep Tac):

(1) Install, operate and maintain the following facilities in the CAMP MACKALL area:

(a) One (1) Auto Manual Swbd, 100 phone service at Headquarters, Tactical Air Force (Prov) Advance.

(b) Terminals for Telephone trunk service from Tactical Air Force (Prov) Advance Swbd as follows:

Three (3) to MANCOM Swbd.

Six (6) to V Corps Headquarters Swbd.

(c) Terminals for Simplex TTY service from Headquarters, Tactical Air Force (Prov) Advance to:

LANGLEY AIR FORCE BASE Operations.

CONGAREE AIRBASE Operations.

SHAW AIR FORCE BASE Operations.

MAXTON AIRBASE Operations.

(d) Terminals for Simplex TTY trunk service from Headquarters, Tactical Air Force (Prov) Advance Swbd to MANCOM Swbd.

Two (2) to V Corps Headquarters Swbd.

(e) Terminal for Duplex TTY service (RTTY) from Headquarters, Tactical Air Force (Prov) Advance to Headquarters, Tactical Air Command, LANGLEY AIR FORCE BASE.

(f) Terminals for private line Service (Telephone) from JOC as follows:

One (1) to LANGLEY AIR FORCE BASE Operations.

One (1) to CONGAREE AIRBASE Operations.

One (1) to SHAW AIR FORCE BASE Operations.

One (1) to MAXTON AIRBASE Operations.

(g) Terminals for HF/RT net to include the following stations.

LANGLEY AIR FORCE BASE.

CONGAREE AIRBASE.

SHAW AIR FORCE BASE.

MAXTON AIRBASE.

Headquarters, Fourteenth Air Force.

Headquarters, Tactical Air Command, LANGLEY AIR FORCE BASE.

(h) Provide CW net terminal NCS at Headquarters, Tactical Air Force (Prov) Advance to include the following stations:

LANGLEY AIR FORCE BASE.

CONGAREE AIRBASE.

SHAW AIR FORCE BASE

MAXTON AIRBASE.

(1) Communications Center, to include:

Message Center.

Crypto Center.

Traffic Center.

(2) Commercial facilities required for above commitments will be arranged for by this Headquarters. All other equipment will be furnished by the 934th Signal Bn (Sep Tac).

(3) Frequencies for radio circuits are contained in Appendix II, this Annex.

(4) Crypto and Authentication Systems to be used will be found in Appendix VIII, this Annex.

c. Base Commanders.

(1) Base Commanders of LANGLEY, CONGAREE, SHAW and MAXTON AIR FORCE BASE, will be responsible for installation, operation and maintenance of terminal communications facilities for all Combat Forces, USAF (Friendly) which are assigned or otherwise attached to their bases during Exercise SWARMER to include:

(a) One (1) terminal for Telephone trunk service to Tactical Air Force (Prov) Advance Swbd.

(b) One (1) terminal for Simplex TTY service from base operations to Tactical Air Force (Prov) Advance Swbd.

(c) One (1) terminal for Private Line service (Telephone) to JOC.

(d) One (1) terminal for HF/RT loop or trunk service to Tactical Air Force (Prov) Advance Swbd.

(e) Net CW Station to Tactical Air Force (Prov) Advance.

(f) Communications Center to include:

Message Center.

Crypto Center.

Traffic Center.

(2) Commercial facilities required for above commitments will be arranged for by this Headquarters. All other equipment will be furnished by the bases concerned.

(3) Frequencies for radio circuits will be listed in Appendix II, this Annex.

(4) Crypto and Authentication Systems will be as indicated in Appendix VIII, this Annex.

d. Tactical Units will:

(1) Crystallize aircraft in accordance with Appendix II, this Annex.

(2) Maintain aircraft radio equipment as required.

APPENDIX X TO ANNEX F

TIME SIGNALS

1. Standard frequency transmissions are made continuously, day and night as a public service by the National Bureau of Standards over it's standard Frequency station, WWV, on the following frequencies:

MC	POWER (KW)
2.5	0.7
5.0	8.0
10.0	9.0
15.0	9.0
20.0	8.5

a. A .005-second pulse may be heard as a faint tick every second except the 59th second of each minute. These pulses may be used for accurate time signals. The audio frequencies are interrupted at precisely one minute before each hour and each five minutes thereafter (59th minute; 4 minutes past hour; 9 minutes past hour, etc.), resuming after an interval of precisely one minute. This one-minute interval is provided to give Eastern Standard Time (ZONE R) telegraphic code and to afford an interval in the checking of radio frequency measurements free from the presence of audio frequencies. The announcements of the stations services and call are given by voice at the hour and half hour. The time interval marked by the pulse every second is accurate to 0.000001 second. The beginning of the periods when the audio frequencies are resumed are synchronized with the basic time service of the U.S. Naval observatory.

2. The TACC will maintain a master time clock. Frequent time check will be made to insure the accuracy of this clock. TADC's and DF stations will obtain frequent time hacks from the TACC to insure all time hacks provided aircraft in flight are properly synchronized and accurate.

ANNEX G

METEOROLOGICAL PLAN

1. General:

a. All units participating in exercise "SWARMER" operating from their home bases will be provided weather data and facilities by local weather detachments. Flight Service will provide any supplemental weather information necessary.

b. The 2060th Mobile Weather Squadron will establish detachments at CONGAREE, MANTON and MACKALL AIR BASES, and at the Joint Operations Center, Hq TAF. These detachments will provide twenty-four (24) hour observation and forecasting service as required.

2. Weather Observation:

a. Pilots will comply with existing Air Force policy in reporting "in-flight" weather phenomena as requested or in reporting any hazardous weather encountered. Proper voice radio procedure for this report will be as outlined in AN 08-15-1, (Radio Facility Chart), Page 153 Par D, "In Flight Weather Reports Sequence".

3. Dissemination:

a. TACC will be provided current weather data on an hourly basis, twenty-four (24) hours a day by the designated detachment.

b. In addition to maintaining current weather maps, special short and long range forecasts will be furnished the JOC as required.

RESTRICTED

SECRET-SWARMER-SECRET

c. POPE AIR FORCE BASE weather detachment will provide ground to air weather information as required, either through the local AACS station or POPE AIR FORCE BASE tower.

ANNEX I

ADMINISTRATIVE ANNEX

1. GENERAL.

a. The Commanding Generals of parent Air Forces are responsible for providing logistical support to their units until such units arrive at the maneuver base.

b. All units will be inspected by Station Commanders at home station prior to departure to insure that units depart with equipment and supplies required for maneuver participation except as noted in Joint Support Agreements shown as Appendices to this Annex.

c. Property accountability and responsibility for supplies and equipment will be maintained throughout the field exercise in accordance with the provisions of AFM 67-1.

d. All requisitions submitted for equipment or supplies for the maneuver will contain a statement that items are required for Exercise SWARMER and Supply priority S-2 with Blue Streak action is authorized per ACMSA041-2-493-F.

e. Supply economy will be enforced at all echelons during the period of the maneuver.

f. Reports of survey for lost, damaged or destroyed TO&E property will be processed upon return of the unit to the home station.

g. Equipment on a loan basis from the maneuver bases that require survey action, will be placed on a report of survey prior to departure of the unit from the maneuver area. Units will not clear the maneuver area until all outstanding accounts have been settled.

2. Supply.

a. POPE AIR FORCE BASE.

(1) Supports Airdrome Control Unit and advance detachments of 314th Troop Carrier Wing and 4th Fighter Interceptor Wing at MAXTON AIR BASE for Class I and III from 15 March 1950 until opening of Carolina Base Section, CUTTER CAMP MACKALL.

(2) Continues to support elements of TFAF as are assigned maneuver sites within the POPE AFB area.

b. SHAW AIR FORCE BASE.

(1) Supports 20th Fighter Bomber Wing and USAF Tenant Units for all Class I, III, IV, and V supplies, and all services required beyond organizational abilities. Reference Appendix 3 to this Annex.

c. LANGLEY AIR FORCE BASE.

(1) Continues support of 84th and 85th Bomb Squadron during maneuver period.

d. MAXTON AIR BASE.

(1) Serves as Distribution Point for Classes I, III and IIIA to units based at MAXTON AIR BASE from 1 April to end of maneuver period.

e. CONGAREE AIR BASE.

(1) Serves as Distribution Point for Classes I, III and IIIA to units based at CONGAREE AIR BASE.

f. FOURTEENTH AIR FORCE

(1) Supports logistically Hq TFAF and all USAF units based in the maneuver area.

(2) Furnishes augmentation personnel for POPE AFB, MAXTON AIR BASE and CONGAREE AIR BASE.

(3) Furnishes supplies and equipment to units based at MAXTON AIR BASE, CONGAREE AIR BASE and POPE and SHAW AIR FORCE BASES, when such supplies and equipment are not available through T/O&E authorizations, but required for maneuver operations. (Reference Appendices 2, 3, and 4).

(4) Furnishes necessary fire and crash equipment and personnel required for airstrip operations within the CAMP MACKALL AREA.

(5) Furnishes necessary Air Combat Maneuver Funds required by USAF units participating in the Exercise, and for necessary repairs, utilities and rehabilitation at MAXTON and CONGAREE AIR BASES.

g. Army Installations.

(1) Carolina Base Section.

(a) SUPPLY POINT, OUTER MACKALL, opens 20 March, serves all USAF units based at MAXTON AIR BASE with Class I and III.

(b) Supply Point, FORT JACKSON, opens 20 March 1950, serves all USAF units at CONGAREE AIR BASE with Classes I and III.

(2) FORT BRAGG, NORTH CAROLINA.

(a) Cross-servicing agreement effective for support of POPE AFB and such minor units satallited thereon prior to opening of Carolina Base Section Supply Points.

h. Navy Installations.

(1) Naval units participating as USAF forces will operate from home stations, with logistical support through established naval channels.

i. Class I.

(1) MAXTON AIR BASE AREA.

(a) Airdrome Control Unit will consolidate requirements of USAF units and forward to Carolina Base Section, estimated three (3) days in advance.

(b) Supply Point distribution will be effected by Airdrome Control Unit from ration breakdown point established at MAXTON AIR BASE.

(c) Consolidated refrigerated facilities will be utilized at MAXTON AIR BASE Supply Point, with distribution direct to organizational messes.

(d) From 15 March until opening of Carolina Base Section Supply Point at CAMP MACKALL AREA, Airdrome Control Unit will submit requisitions to POPE AFB.

(2) SHAW AIR FORCE BASE.

(a) 20th Fighter Bomber Wing will provide Class I requirements to USAF Tenant Units.

(3) CONGAREE AIR BASE.

(a) USAF units will requisition on Supply Point, Carolina Base Section, FORT JACKSON. Supply Point distribution from consolidated requirement as determined by Airdrome Control Unit.

(4) LANGLEY AIR FORCE BASE.

(a) LANGLEY AFB will continue Class I support of 84th and 85th Bomb Squadrons.

j. Class II.

(1) MAXTON AIR BASE.

(a) USAF units will enter maneuver area with such individual and organizational equipment as required for the maneuver period, except as noted in Joint Use Agreement between 4th Fighter Wing, 314th Troop Carrier Wing, and 14th Air Force, attached as Appendix 2, 14th Air Force will furnish items in excess of T/O&E and T/A authorizations, and items specified in cited Joint Use Agreement, to avoid excess transportation costs.

(b) Thirty day level will be taken to maneuver area.

(c) All troop carrier and transport type aircraft will arrive at maneuver base with one parachute for each passenger seat, one loading ramp and one air cargo mooring kit per aircraft.

(2) SHAW AIR FORCE BASE.

(a) USAF Tenant Units will bring to SHAW AIR FORCE BASE all T/O&E and T/A equipment required to accomplish their assigned mission.

(b) Additional requirements will be furnished by SHAW AIR FORCE BASE and 14th Air Force. (Reference Appendix No. 3).

(c) Transport aircraft will arrive with one parchute for each passenger seat, one loading ramp and one air cargo mooring kit for each aircraft.

(3) CONGAREE AIR BASE.

(a) USAF units will arrive with necessary T/O&E and T/A equipment and supplies required to accomplish assigned mission.

(b) Additional requirements will be provided by 14th Air Force, (Reference Appendix No. 4).

(c) Transport aircraft will arrive with one parachute for each passenger seat, one loading ramp and one air cargo mooring kit for each aircraft.

(4) LANGLEY AIR FORCE BASE.

(a) Units based at LANGLEY AF BASE will furnish T/O&E and T/A equipment required to accomplish their assigned mission.

k. Class III.

(1) MAXTON AIR BASE.

(a) Airdrome Control Unit will submit consolidated vehicle gas and oil requirements for base units to Carolina Base Section, estimated three (3) days in advance.

(b) Supply point distribution OUTER CAMP MACKALL and MAXTON AIR BASE.

(2) SHAW AIR FORCE BASE.

(a) Requirements for base and tenant units will be procured through normal channels.

(3) CONGAREE AIR BASE.

(a) Motor gas and oil consolidated requirements for base units will be requisitioned by Airdrome Control Unit from Supply Point, Carolina Base Section, FORT JACKSON.

(4) LANGLEY AIR FORCE BASE.

(a) Requirements for units based at LANGLEY AFB will be processed through normal channels.

l. Class IIIA.

(1) Requirements for avgas and JP-1 fuel for all USAF units will be determined by Hq 14th AF and submitted to Hq ConAC.

(2) Hq ConAC, will effect necessary contractual arrangements to make available through local contractors the requirements of each maneuver base.

(3) Base supply officers will contact appropriate local contractors and arrange for scheduling of tank cars and/or trucks to appropriate maneuver bases.

(4) Hq. 14th AF will notify the foregoing officers of names and locations of avgas contractors.

(5) Similar procedures will be effected for procurement of necessary aircraft oils.

m. Class IV.

(1) USAF units will take the field with necessary Class IV supplies to include automotive spares to sustain their operation during the maneuver period.

(2) Expendable office supplies, cleaning materials, toilet paper, etc, will be provided from unit stocks and taken to maneuver area, except as indicated in Appendices 2, 3 and 4.

n. Class IVA.

(1) All participating units moving to maneuver bases will carry supplies sufficient to support their requirements during the maneuver period. Such supplies to include engines, oxygen, and normal maintenance spares.

o. Class V and VA.

(1) None required other than for security purposes; furnished by units.

(2) No live ammunition will be in the possession of individuals or units in the field excersise except that specifically authorized by the Commanding General, Task Force Air Force. Upon arrival in the maneuver area, each unit commander will certify in writing to the Commanding General, Task Force Air Force, that no live ammunition is on hand or in the possession of individuals of his unit.

p. Resupply.

(1) Resupply of Classes II and IIA and IV and IVA will be limited to emergency and AOCP requirements.

(2) Units based at MAXTON AIR BASE will effect resupply and AOCP procedures through home stations via assigned aircraft.

(3) SHAW AF BASE Supply will process AOCP requests for USAF Tenant Units.

(4) USAF units based at CONGAREE AIR BASE will process resupply and AOCP requirements through MATS channels.

(5) Units based at LANGLEY AF BASE will effect resupply through normal channels.

q. Salvage.

(1) Salvage generated at MAXTON AIR BASE will be turned into POPE AF BASE.

(2) Salvage generated at CONGAREE AIR BASE will be turned in to SHAW AF BASE.

(3) Salvage generated by base and tenant units at SHAW and LANGLEY AF BASE will be processed by station salvage officers.

3. Transportation.

a. Movement.

(1) Units moving to maneuver bases from home stations will move in accordance with movement plan shown in Appendix 1 to this Annex.

(2) Transportation officers at home stations of units concerned will be responsible for the movement of vehicles, via rail or convoy, from points of departure to destination, to include compliance with existing state laws and military regulations, and coordination with Commanding General of appropriate Army area concerned.

(3) Organizational aircraft will be utilized to the maximum.

(4) All movement will utilize the most economical mode of transportation possible.

(5) Loading and unloading of transport aircraft during the maneuver period to include necessary personnel and equipment, will be a responsibility of 7th Medium Port Units at maneuver bases.

4. Services.

a. Medical - Installations.

(1) MAXTON AIR BASE AREA.

(a) Unit-medical facilities will be supplemented by evacuation to, Field Hospital, V Corps, MAXTON AIR BASE for actual casualties.

(2) CONGAREE AIR BASE.

(a) Units medical facilities will be supported by Base Hospital, FORT JACKSON, SOUTH CAROLINA.

(3) SHAW AIR FORCE BASE.

(a) Base facilities will support all USAF units based at SHAW AFB.

(4) Actual deaths incurred during the Exercise will be evvacuated in accordance with Annex XV to General Plan, "SWARMER", dated 16 February 1950.

b. Medical - Health and Sanitation.

(1) Immunization will be current in accordance with existing regulations.

c. Maintenance.

(1) Current maintenance policies remain effective.

(2) Organization and field maintenance will be performed by all units to the maximum extent consistant with availability of equipment and skill of personnel.

(3) Aircraft, vehicles and other equipment requiring repair beyond the capabilities of organizations will be reported to 14th AF.

d. Construction and Repair.

(1) Anticipated and minimum requirements for repair construction and rehabilitation of facilities at MAXTON and CONGAREE AIR BASES will be performed by Airdrome Control Units except renovation of fuel storage system at MAXTON AIR BASE.

which will be performed by the 14th AF.

e. Laundry.

(1) USAF units based at MAXTON AIR BASE and POPE AFB will utilize the facilities of the Post QM Laundry, FORT BRAGG, in accordance with schedules arranged by the Airdrome Control Unit MAXTON AIR BASE, and the Supply Officer POPE AFB, respectively.

(2) USAF units based at CONGAREE AIR BASE will provide laundry service by local contract.

(3) USAF Units based at SHAW AND LANGLEY AFB will utilize existing base facilities.

f. Post Exchange.

(1) MAXTON AIR BASE AREA will be serviced by branch post exchange operated by FORT BRAGG.

(2) USAF Units in CONGAREE AIR BASE will be serviced by branch exchanges from FORT JACKSON, SOUTH CAROLINA.

(3) USAF Units at POPE, LANGLEY and SHAW AFBBASES will utilize current facilities.

g. Funds.

(1) Requirements for air combat maneuver funds will be computed by all USAF participating units and furnished to Hq, 14th AF by 15 March 1950.

(2) Allocation of fund requirements will be effected by Hq, 14th AF for expenditures directly required for participation in Exercise SWARMER.

5. Personnel.

a. Troop Strength Reports and Records.

(1) Strength of units will be as authorized in T/O&E applicable to individual unit.

(2) Reports. All Air Force units who move their administrative headquarters to operations area of SWARMER will prepare and forward morning reports and other required personnel reports to the Commanding General of the respective Air Force headquarters to which they are assigned, attention: Director of Statistical Services. Other units of the Air Force who have personnel on duty with subject operations will make appropriate remarks daily in the remarks section of their morning report and indicate the total number of officers and airmen who are on TDY with Exercise SWARMER. Detachments participating in subject exercise will not prepare detachment reports except as may be required by their parent unit. It will be the responsibility of the parent Air Force units to forward all instructions and directives to organizations concerned for preparing personnel reports.

(3) Records. Essential records and allied papers will accompany units while in maneuver area.

b. Replacements.

(1) Current policies will govern. Actual replacements will not join units after their departure from home station until their return thereto.

c. Personnel Procedures.

(1) Leaves and passes. Personnel participating in the exercise will not be granted leave, except for emergency reasons. Passes may be granted at the discretion of unit commanders if off duty time permits. Uniform while on pass will be class "A" Summer.

d. Morale.

(1) Pay of Airmen. All units ordered to maneuver area will be paid by the finance officer regularly paying the unit at home station. Unit Commanders will appoint Class "A" Finance Agent who will arrange with home station finance officer to make payment of airmen and officers in the maneuver area at the regular pay roll date.

(2) Payment for rations issued in kind. All Airmen authorized to ration separately will be removed from such status by appropriate Commander prior to departure from home station. They will not again be authorized separate rations until they return to home station. Officers eating at troop messes will pay cash for all meals to the mess officer of the mess in which meals are consumed.

(3) Personal affairs. No dependents will accompany sponsors to maneuver area. All Commanders will instruct officers and airmen prior to departure to arrange their personal affairs to insure that a minimum of headship is caused dependents by the absence of heads of families during the maneuver period.

(4) Special Services. Every effort will be made to furnish entertainment to airmen during pre-and post maneuver periods by Air Force Base Commanders.

(a) All units will bring the minimum essential athletic equipment from home station.

(5) Postal Service. Mail will be handled, insofar as practicable, in accordance with procedures for a theater of operations, (Reference Chapter 5, TM 12-205.)

(a) All mail, official and personal, addressed to organization or Air Force personnel on the maneuvers, except as noted in (b) below, will be addressed with name, grade, service number, number of Squadron, Group, Wing or next higher element to which the unit is assigned or attached and addressed to the Maneuver Base to which the unit is ordered from home station.

Operation Plan
TFAF No. 3-50

EXAMPLE: Pvt Joh Jones, 32 000 000
60th TC Sq, 385 TC Wing
Shaw AFB, S.C.

(b) All mail addressed to observers, will be plainly marked "Observer" followe d by "Visitors Bureau", Exercise Exercise Swarmer, Fort Bragg, N. C.

EXAMPLE: Capt John Smith AO 275 000
Observer - Vistor's Bureau
Exercise Swarmer
Fort Bragg, N.C.

e. Civilian Personnel: will not participate in this Exercise.

f. Law and Order.

(1) The Provost Marshal, FORT BRAGG, N. C. is responsible for coordination with Hq. V Corps, Hqs TFAF and North Carolina State Police with reference to military police functions and responsibilities in the FORT BRAGG, CAMP MACKALL - LAURINBURG-MAXTON AREA. The Provost Marshal, FORT JACKSON, S. C. will effect similiar coordination for South Carolina.

(2) The Commanding General, V.Corps and Commander Carolina Base Section, is responsi ble for law and order and traffic control in the sectors of the maneuver area under their control.

(3) Commanding General, TFAF, is responsible for traffic control and maintenance of law and order in his sector of operations.

(4) Troops will be contained within the sector of operations. Collection points will be operated to serve as control points for apprehension of absentees and stragglers. (See para, g, below).

(5) Courts Martial Jurisdiction. For the purpose of the exercise, all personnel assigned to Air Force units will come under the Commanding General, 14th Air Force for General Court Martial jurisdiction and Article of War 104 jurisdiction when appropriate. Attachment of individuals or units for administration includes attachment for Courts-Martial Jurisdiction.

(6) Claims. The responsibility for designation of claims officers to investigate accidents or incidents which might result in claims by or against the Government rests with the Commanding Officer of Groups or commensurate units. (Ref AFR 112 series).

g. Prisoners of War.

(1) Facilities needed for handling prisoners of war is the responsibility of the Commanding General, V Corps and Commanding General, TFAF.

Operation Plan
TFAF No. 3-50

(2) Captured personnel will not be held longer than 48 hours for interrogation. Chief Umpire is responsible for daily exchange of Prisoners of US and Aggressor Forces.

h. Miscellaneous Personnel Activities.

(1) Public Information activities will be as prescribed by the Commanding General TFAF.

(2) Identification tags will be worn by all personnel participating in the Exercise.

6. Miscellaneous.

a. Location of Headquarters.

(1) Hq. TASK FORCE SWARMER, FORT BRAGG, NORTH CAROLINA.

(2) Hq. TFAF, OUTER CAMP MACKALL, NORTH CAROLINA.

(3) Hq. V Corps OUTER CAMP MACKALL, NORTH CAROLINA.

(4) Hq. 14th Air Force, ROBINS AIR FORCE BASE, GEORGIA.

(5) Hq. 9th Air Force, LANGLEY AIR FORCE BASE, VIRGINIA.

(6) Hq. Carolina Base Section, OUTER CAMP MACKALL, N. C.

b. Special Reports.

(1) Unit Commanders will submit the following reports to commander of installations to which units are assigned for maneuver participation, forty-eight (48 hours prior to departure of personnel from home station. Report will apply to all movements shown in Appendix 3 and will include.

(a) Departure date.

(b) ETA.

(c) Troop Strength (roster of troops).

c. Administration.

(1) Uniform for maneuver period will be Summer.

APPENDIX I TO ANNEX I

MOVEMENT PLANS

1. GENERAL. Air Force organizations will move from home stations to the maneuver area as prescribed below. Redeployment from maneuver area to home stations will be as prescribed by the TFAF at a later date. Maneuver Base Commanders will be notified by the Unit Commanding Officers seven (7) days in advance of the arrival of personnel, giving strength of officers and airmen for necessary arrangements for rations.

2. 314th Troop Carrier Wing.

a. Scheduling.

(1) Personnel and equipment for the Airdrome Control Unit will arrive at MAXTON AIR BASE in sufficient time to be operational by 15 March 1950.

(2) The advance party will arrive at MAXTON AIR BASE not later than 1 April 1950.

(3) The Main Body will arrive at MAXTON AIR BASE not later than 13 April 1950 and the entire Wing at MAXTON AIR BASE will be in operational readiness by 15 April 1950.

b. Type of Movement.

(1) The Airdrome Control Unit will move by motor convoy with heavy equipment to be shipped by rail.

(2) The Advance Party will move by assigned aircraft and motor convoy.

(3) The Main Party will move by assigned aircraft and motor convoy.

3. 4th Fighter-Interceptor Wing.

a. Scheduling.

(1) Personnel and equipment for the Airdrome Control Unit will arrive at MAXTON AIR BASE in sufficient time to be operational by 15 March 1950.

(2) The Advance Party will arrive at MAXTON AIR BASE not later than 1 April 1950.

(3) The Main Body will arrive at MAXTON AIR BASE to be operational by 15 April 1950.

RESTRICTED

SECRET-SWARMER-SECRET

b. Type of Movement.

(1) All personnel and equipment will move by aircraft under the control of the Commanding General, 9th Air Force.

4. 7th Troop Carrier Squadron.

a. Scheduling.

(1) The Advance Liaison Detachment will arrive at the maneuver base not later than 1 April 1950.

(2) The Main Body will arrive at the maneuver base not later than 15 April 1950 and the squadron operational by 15 April 1950.

b. Type of Movement.

(1) All personnel and equipment will move by assigned aircraft.

5. 84th and 85th Bomb Squadrons.

a. Will operate from home station, LANGLEY AFB, with no movement involved.

6. 20th Fighter Bomber Wing.

a. Will operate from home station, SHAW AFB, with no movement involved.

7. 161st Tactical Reconnaissance Squadron.

a. Will operate from home station, SHAW AFB, with no movement involved.

8. 502nd Tactical Control Group.

a. Will operate in the Maneuver Area as directed by TFAF. Assigned vehicles will be used for all movement.

9. 934th Signal Battalion.

a. Will operate in the Maneuver Area as directed by TFAF. Assigned vehicles will be used for all movement.

10. 1st Shoran Beacon Unit.

a. Will operate in the Maneuver Area as directed by TFAF. Assigned vehicles will be used for all movement.

11. 4th Liaison Flight.

a. Will operate in the Maneuver Area as directed by TFAF.

12. Troop Carrier Units (Reserve).

a. Scheduling.

(1) Advance liaison detachments (ref appendix 3) will arrive SHAW AFB not later than 15 April 1950.

(2) Remaining units will arrive SHAW AFB not later than 27 April and be operational by 29 April 1950.

b. Type of Movement.

(1) Personnel and equipment will move via assigned aircraft.

13. MATS.

a. Scheduling.

(1) Will arrive at CONGAREE AIR BASE in sufficient time to be in operational readiness by 15 April 1950.

b. Type of Movement.

(1) Personnel and equipment will move via assigned aircraft.

APPENDIX II TO ANNEX I

SUPPORT AGREEMENT - MAXTON AIR BASE

1. GENERAL. This appendix delineates mutual support agreed upon by and between Commanding General, 14th Air Force, Commanding General 314th Troop Carrier Wing, and Commanding General, 4th Fighter Interceptor Wing, for joint tenancy for MAXTON AIR BASE during the period 1 April 1950 to 15 May 1950 for participation in Exercise SWARMER.

2. Administration.

a. The Commanding General, 314th Troop Carrier Wing will have command responsibility of common administrative and logistic functions of the Air Base.

(1) To perform these functions, there will be established an Airdrome Control Unit to be manned and equipped by Commanding General, 314th Troop Carrier Wing augmented by the Commanding General, 4th Fighter-Inteceptor Wing as mutually agreed upon between the two commanders concerned.

(2) Administrative and Logistic responsibilities of the Airdrome Control Unit will include the following:

(a) Administrative operation of base headquarters.

(b) Base Operations and fire and crash protection.

(c) Repairs and utilities functions.

(d) Class I supply point distribution. Consolidation of requirements and submission to Carolina Base Section.

(e) Class III and IIIA procurement, storage and issue. Coordination with contractor and Carolina Base Section for delivery of fuel to MAXTON AIR BASE.

(f) Internal security.

3. Activation of MAXTON AIR BASE

a. The Commanding General, V Corps will acquire use of the MAXTON AIR BASE and certain facilities thereat for use of USAF Units during the period 13 March 1950 to 15 May 1950.

b. The Airdrome Control Unit will prepare air field for occupancy by accomplishing the following prior to 1 April 1950.

(1) Appoint a responsible officer who will establish an M/R Account with POPE AFB for those items furnished by Headquarters, 14th Air Force and FORT BRAGG.

(2) Renovation of water and sewage systems.

(3) Renovation of electrical system.

(4) Arranging with local Utilities Companies for service during period of Exercise.

(5) Erection of washing, bathing and latrine facilities.

(6) Repairs to buildings, grounds, roads, runways and parking aprons as approved by Headquarters, 14th Air Force.

(7) Installation of field lighting system.

(8) Clearing bivouac areas.

(9) Cutting grass on airdrome.

(10) Repairing wind direction indicator.

c. The Commanding General, 14th Air Force will support the Commanding General, 314th Troop Carrier Wing, Commanding General, 4th Fighter Interceptor Wing, and Commanding Officer, Airdrome Control Unit, as follows:

(1) Arrange for renovation of fuel storage systems by Contract, Ready date - 1 April 1950.

(2) Arrange with Carolina Base Section, FORT BRAGG, and POPE AFB for local support of USAF Units during period of Exercise. Local support will consist of the following.

(a) Class I supplies.

(b) Class III supplies.

(c) Exchange, laundry and theater services.

(3) Submit Class IIIA requirements to highter headquarters and arrange for tank car delivery to MAXTON AIR BASE as required.

(4) Furnish 4th Fighter Interceptor Wing general and special purpose vehicles required to accomplish their assigned mission. This does not include vehicles, equipment, ground handling equipment and tools peculiar to assigned aircraft.

(5) Furnish Commanding Officer, Airdrome Control Unit, general and special purpose vehicles, equipment, tools and personnel beyond the capabilities of the Commanding General, 314th Troop Carrier Wing, and Commanding General, 4th Fighter Interceptor Wing.

Operation Plan
TFAF No. 3-50

4. Operations.

a. The 314th Troop Carrier Wing, 4th Fighter Interceptor Wing and Airdrome Control Unit will be under Operational Control of TFAF while based at MAXTON AIR BASE.

APPENDIX III TO ANNEX I

SUPPORT AGREEMENT - SHAW AIR FORCE BASE

1. GENERAL. This appendix delineates the support agreed upon by the Commanding General, 14th Air Force and the Commanding General, 20th Fighter Bomber Wing, to be furnished USAF Tenant Units at SHAW AFB during Exercise SWARMER.

2. Administrative and Logistical Support.

a. Facilities.

(1) Billeting and Messing.

(a) 20th Fighter Bomber Wing will furnish barracks, cots, bedding, kitchen and mess equipment, etc., for housing and messing for 100 officers and 150 airmen of the USAF Tenant Units.

(2) Administrative and Operational Office Space.

(a) 20th Fighter Bomber Wing will furnish required administrative office space, operation briefing rooms, etc., to USAF Tenant Units in locations mutually agreed upon.

(3) Communications.

(a) 20th Fighter Bomber Wing will provide necessary telephones, point to point radio, crytographic equipment required for operating personnel of the USAF Tenant Units.

(4) Refueling and Crash Fire Requirements.

(a) To be furnished by 20th Fighter Bomber Wing, with augmentation personnel from USAF Tenant Units if required.

(5) Maintenance Shops, Working and Parking Areas.

(a) 20th Fighter Bomber Wing will furnish parking space for a maximum of thirty-six cargo type aircraft, and the use of such common shop facilities and equipment as may be used by personnel of USAF Tenant Units for repair of unit aircraft. No covered maintenance area will be available.

b. Funds.

(1) 14th Air Force will provide ACW funds to SHAW AFB for requirements generated by USAF Tenant Units during the maneuver period.

(2) Local procurement of items peculiar to Exercise SWARMER will be charged to ACW Funds.

c. Supply.

(1) Class I - Furnished by 20th Fighter Bomber Wing.

(2) Class II and IIA.

(a) USAF Tenant Units will bring to SHAW AFB such items of T/O&E, T/A and individual equipment required for performance of their maneuver mission.

(b) 14th Air Force will provide such equipment, special purpose vehicles and ground handling equipment required but impracticable for air shipment from home station and not available from 20th Fighter Bomber Wing.

(3) Class III and IIIA.

(a) Avgas, JP-1 and aviation oils will be made available at SHAW AFB for all USAF Units as prescribed in paragraph 2 Annex I.

(b) Motor vehicle gasoline and oils will be procured by 20th Fighter Bomber Wing from normal sources for USAF Tenant Units on a reimburseable basis from ACM Funds.

(4) Class IV and IVA.

(a) USAF Tenant Units will bring supplies sufficient to support assigned aircraft during the maneuver period.

(b) Emergency resupply and AOCP items will be effected by 20th Fighter Bomber Wing.

d. Transportation and Services.

(1) Vehicle transportation required by USAF Tenant Units for transporting personnel to and from working and billeting areas will be furnished by 20th Fighter Bomber Wing.

(2) Normal base services, including medical, laundry, post exchange, theaters, etc., will be furnished to the USAF Tenant Units by the 20th Fighter Bomber Wing.

3. Operations.

a. USAF Tenant Units will be under the operational control of Troop Carrier Force while on tenant status.

Operation Plan
TFAF No. 3-50

4. Miscellaneous.

a. USAF Tenant Units will provide a liaison supply officer to 20th Fighter Bomber Wing by 15 April 1950, to act as responsible officer for use of non-expendable equipment and supplies furnished by 20th Fighter Bomber Wing.

APPENDIX IV TO ANNEX I

SUPPORT AGREEMENT - CONGAREE AIR BASE

1. GENERAL. This appendix delineates the mutual support agreed upon by the Commanding General, MATS, Commanding General 62nd Troop Carrier Wing and the Commanding General, 14th Air Force for the use of CONGAREE AIR BASE during Exercise SWARMER.

2. Administration. The 14th Air Force will make the necessary arrangements with Adjutant General, South Carolina for the use of CONGAREE AIR BASE and certain facilities thereat as listed in paragraph 3.

3. Facilities.

a. Billeting and messing.

(1) Barracks and mess installations are available for approximately 2000 men.

(2) No bedding or mess equipment available.

b. Administrative and Operational Buildings.

(1) Sufficient covered space is available for administrative requirements, and for base operations, briefing, etc.

(2) No hangar space is available for maintenance work.

(3) Covered storage is available for base supply activities.

c. Gasoline Storage.

(1) Operational 100,000 gal avgas storage is available, less normal operational requirements of ANG.

(2) 25,000 gal motor vehicle gas storage is available.

d. General and special purpose vehicles:

(1) Crash and Structural Fire Fighting.

(a) 1-125 - Crash Trucks.

1-135 - Crash Trucks.

1- Ambulance.

(2) No refueling units can be furnished by ANG.

(3) No general or special purpose vehicles or ground handling equipment of any kind can be furnished by the ANG.

(4) Building No. 72, roof and concrete floor only, may be utilized for motor pool activities.

e. Utilities.

(1) Water, sewage and electricity will be available.

4. USAF Units will be responsible for provision of:

a. All aircraft crews and supporting maintenance and supply personnel.

b. Organizational equipment required to support the C-54 aircraft during the maneuver period to include:

(1) 20 day level of class IVA supplies peculiar to C-54 aircraft.

(2) Necessary administrative personnel for performing the operational mission.

c. Individual equipment, to include mess kits, clothing, and toilet articles.

5. The 14th Air Force will support the operational functions of USAF Units by providing normal base housekeeping functions.

a. To perform these functions, the 14th Air Force will establish an Airdrome Control Unit, which will be responsible for:

(1) Administrative operations of base headquarters.

(2) Operating messing facilities for USAF Units.

(3) Renovation, Repairs and Utilities functions.

(4) Maintaining and operating general and special purpose vehicles required.

(5) Medical, laundry, and exchange services.

(6) Internal Security of Air Base.

(7) Necessary transient services.

(8) Provision of billets for USAF personnel to include cots and blankets only.

(9) Class I.

(a) Effecting necessary arrangements with Supply Point, Carolina Base Section, FORT JACKSON, for daily requirements.

(b) Operating ration breakdown point at CONGAREE AIR BASE.

(10) Class III.

(a) Arranging with supply point Carolina Base Section, FORT JACKSON for daily requirements.

(b) Operating storage and distribution point at CONGAREE AIR BASE.

(11) Class IIIA.

(a) Arranging with designated contractor for delivery of daily avgas requirements.

(b) Operating avgas storage and issue point.

(c) Operating aircraft refueling units to provide necessary service to USAF Units and transient aircraft.

(12) Operations of crash and fire equipment.

b. To support the Airdrome Control Unit, the 14th Air Force will provide all personnel, supplies, equipment, vehicles, and fuel required.

c. The 14th Air Force will arrange with SHAW AFB for the following:

(1) Purchasing and Contracting Services required at CONGAREE AIR BASE.

(2) Provisions from base stocks or by requisition, supplies and equipment designated by 14th Air Force for support of CONGAREE AIR BASE.

D/M Report Form No. 1 (Daily as of 2400 hrs)

TO: Commanding General, Task Force Air Force

FROM: (Applicable Unit)

(a) Number aircraft on hand

(b) Number aircraft in commission

(c) Number aircraft ACCP

(d) Number aircraft out for maintenance

(e) Number aircraft lost from accidents

(f) Number aircraft damaged (simulated)

(g) Number aircraft destroyed (simulated) (f) & (g) as ruled by Air Umpires)

(h) Number hours flown

(i) Amount of fuel consumed by type in gallons (Aviation)

(j) Amount of Engine oil consumed by type on gallons (Aviation)

(k) Oxygen consumed (No. of sylinders)

(l) Number engine changes

(m) Number vehicles on hand

(n) Number vehicles VDP

(o) Number vehicles out for maintenance

(p) Number vehicles lost through accident

(q) Amount gasoline consumed (vehicles)

(r) Amount of oil consumed in quarts (vehicles)

(s) Number special purpose vehicles on hand

(t) Number special purpose vehicles VDP

(u) Number special purpose vehicles out for maintenance

(v) Number special purpose vehicles lost through accident

Note: The above information will be furnished by breakdown according to symbol and will include only those portions that pertain to the unit.

TAB A

For Example:

(a) 25

(b) 20

(d) 2

(h) 30

(i) 6000 dash 100/130

(j) 100 gals 1120
etc.

d. Above report would indicate that as of midnight 25 A/C are on hand, 20 A/C in commission; no A/C AOCP; 2 A/C out for maintenance; 30 hours flown that day. 6000 gallons of 100/130 grade AvGas consumed that day: 100 gallons of 1120 oil consumed that day: etc.

General Plan, Exercise Swarmer

Changes)
No. 5)

22 March 1950

I. All previous changes are included herein. Changes 1 thru 4 are rescinded.

II. Cover letter: Date is changed from 6 February 1950 to 17 February 1950.

III. The following general changes apply to the General Plan and to all Annexes and Appendices thereto.

A. All references to Fort Jackson and Congaree Airfield, S.C. are changed to read: "Greenville Air Force Base, S.C." except as indicated in IV below.

B. All references to Tactical Air Force (Prov) are changed to read: "Air Task Force SWARMER" except as indicated in par 3b(4) to General Plan.

IV. The following specific changes are applicable to paragraphs as indicated:

GENERAL PLAN:

I. General

* * * * * * * * * *

3. Situation:

* * * * * * * * *

b. Friendly

* * * * * * * *

(2) Theater Army, composed of the V, X, XI, and XII Corps, has the mission of defending the Gulf and Atlantic coastline from the Mississippi - Louisiana boundary to Elizabeth City, N. C. with Corps mission as follows:

* * * * * * * *

(b) X Corps defends the Gulf Coast from the Mississippi - Louisiana boundary to Applachicola, Florida.

* * * * * * *

(3) Theater Air Force has the mission of the air defense of the Gulf and Atlantic coastline from the

the Mississippi - Louisiana boundary to Elizabeth City, N. C. and the Tactical Air Support of units of the Third Army as determined by SET.

(4) Delete and substitue therefor: "With the AGGRESSOR penetration into the Carolinas, SET establishes TASK FORCE "SWARMER" for the purpose of mounting an airborne operation to secure the Camp Mackall, N.C. Fort Bragg, N.C. - Fayetteville, N.C. area, and to dislodge AGRESSOR from the Atlantic seacoast. To accomplish this, V Corps is released from the Theater Army and Tactical Air Force (Prov) is released from the Theater Air Force, and are assigned to TASK FORCE "SWARMER". The 11th and 82nd Airborne Divisions and the 3rd Infantry Division (CPX only) are assigned to V Corps. AIR TASK FORCE "SWARMER" is established (General Order Number 8, Headquarters - Maneuver Commander, Exercise SWARMER, 16 March 1950), and is assigned the following USAF units:

Tactical Air Force (Provisional)	
4th Fighter-Interceptor Wing	3 Squadrons (Ftr) 2 Squadrons (Lt (Bomber)
20th Fighter-Bomber Wing	3 Squadrons
314th Troop-Carrier Wing	6 TC Squadrons
62nd Troop-Carrier Group	1 TC Squadron
161st TAC Reconnaissance Sq	1 Squadron
Navy Air Group	5 Squadrons
VMR 153	1 TC Squadron
Strategic Air Transport Wing (Prov)	MATS
363rd Reconnaissance Tech Squadron	1 Squadron
502nd TAC Control Group (-)	
934th Signal Bn	

Due to the commitment of all U.S. Forces in the Southeastern Theater, a ground link-up with the airborne forces is not contemplated for more than 30 days, and therefore supply must be maintained by airlift.

* * * * * * * * * *

II. Concept

5. Mission - Add paragraph "i"

* * * * * * * * * *

i. To test the feasibility of supporting and military combat operation by strategic airlift.

* * * * * * * * * *

10. Administrative Arrangements: Delete paragraphs as indicated and substitute therefor:

* * * * * * * * * *

0188

d. The Commanding General, Fort Bragg, is responsible for:

Add:

(3) The provision of Exchange facilities for troops stationed at Greenville Air Force Base, as agreed and coordinated with the Commander Carolina Base Section.

e. The Commanding General, Fort Jackson, is responsible for:

(1) Delete entire sub-paragraph.

(2) Redesignate to be (1).

f. The Commanding General, V Corps, is responsible for:

* * * * * * * * *

(3) Conduct of United States Forces Army tactical operations, training, administration, and logistical support for forces under his command during the period 1 April - 8 May 1950.

* * * * * * * * *

(5) Acting as Commander, Carolina Base Section prior to 20 March 1950 for planning of administration and logistical support to V Corps during the period 1 April - 8 May 1950.

ANNEX I

1. Command Responsibilities: Amend to read

* * * * * * * * * *

b. United States Forces, (Task Force SWARMER): Lieutenant General John R Hodge USA, will command Task Force SWARMER, utilizing Maneuver Headquarters Staff.

* * * * * * * * * * *

(3) Carolina Base Section: Brigadier General Paul F Yount.

0190

AMENDMENTS

To Directive for Joint (Army-Air Force) Exercise, FY 1950

1. Amend paragraph 4, to read as follows:

* *) * *

4. Participating forces:

a. Maneuver Commander is assigned the following troops and units to implement the concept stated in paragraph 3:

(1) Army:
Corps headquarters
2 Airborne divisions
1 Infantry division hq (CPX)
1 Infantry RCT
AGGRESSOR CHQ units, Ft Riley, Kansas
Necessary combat and service support.

(2) Air Force:
Tactical Air Force (Prov)
7 Troop carrier squadrons
Additional transport aircraft as required
4 Fighter groups minus 2 squadrons
2 Light bomb squadrons
2 Tactical reconnaissance squadrons
Elements of tactical control group
Elements of Signal battalion
1 Liaison flight
Detachment SHORAN beacon unit
1 Reconnaissance technical squadron
AACS and AWS support as required by Maneuver Commander.

All Air Force units listed above organized on wing base plan will furnish necessary supporting units for combat groups.

Incl #2

0220

b. Reserve components -- no change.

c. Maneuver Commander will publish general plan indicating use of assigned forces and plan of maneuver.

* * * * *

2. Delete Inclosure 1 to directive.

3. Reserve components - Employment of ANG and Air Reserve units and personnel is authorized. Maneuver Commanders requirements will be coordinated by Commanding General, Continental Air Command.

4. Tasks and Responsibilities.

a. Continental Air Command will:

(1) Designate the Deputy Chief Umpire.

(2) Coordinate the Maneuver Commanders requirements for ANG and Air Reserve units.

(3) Provide necessary augmentation for Tactical Air Force Headquarters (Provisional), based on requests submitted by Commanding General, Tactical Air Force (Provisional).

(4) Process fuel and ordnance requisitions as requested.

(5) Monitor entire operation and provide all other assistance within scope of funds available.

b. Tactical Air Command will:

(1) Monitor Air Force activities during the exercise to insure compliance with existing doctrine and procedures, and render all assistance possible to the Maneuver Commander and Tactical Air Force (Provisional).

c. Tactical Air Force (Provisional) will:

(1) Be responsible for tactical employment of Air Force units assigned this exercise.

(2) Be responsible for the operation of the Air Force Combat Operations Section of the Joint Operations Center, and supervision of the Tactical Control System.

(3) Forward requests for augmentation of Tactical Air Force (Provisional) to Headquarters Continental Air Command for this exercise. (Requests to include rank, MOS, and reporting date)

THIS PAGE IS DECLASSIFIED IAW EO 13526

(4) Make available to Fourteenth Air Force necessary information for prompt submission of budget estimate and justification.

(5) Determine exact requirements and troop list of units allocated to this exercise in paragraph 3, above.

(6) Forward to Headquarters, Continental Air Command, copies of all orders and instructions issued to subordinate units.

(7) Prepare and publish the Air Operation Plan for the conduct of this exercise and issue necessary implementing orders and instructions to all participating Air Force units.

(8) Submit requests for movement of all Air Force units, to Headquarters, Continental Air Command, in accordance with paragraph 11, Air Force Regulation 75-20 immediately upon receipt of this directive.

(9) Issue movement orders for all Air Force units upon receipt of authority from Headquarters, Continental Air Command.

(10) Establish immediate liaison and conduct concurrent planning with appropriate agencies.

d. Fourth Air Force will:

(1) Train, equip, and make available on request of Commanding General, Tactical Air Force, required elements of those Fourth Air Force units assigned to this exercise (paragraph 3, above).

(2) Furnish Commanding General, Tactical Air Force, for submission of movement requests to Headquarters, Continental Air Command, necessary information concerning participating Fourth Air Force units.

Directive for the Implementation of Joint Army-Air Force Exercise, Fiscal Fiscal Year 1950 - "Swarmer" (Contd)

(3) Submit detailed budget estimate and justification to Headquarters, Continental Air Command, for Fourth Air Force units participating in the maneuver.

e. Ninth Air Force will:

(1) Train, equip, and make available on request of Commanding General, Tactical Air Force, required elements of those Ninth Air Force units assigned to this exercise (paragraph 8, above).

(2) Furnish Commanding General, Tactical Air Force, for submission of movement requests to Headquarters, Continental Air Command, necessary information concerning participating Ninth Air Force units.

(3) Submit detailed budget estimate and justification to Headquarters, Continental Air Command, for Ninth Air Force units participating in the maneuver.

f. Fourteenth Air Force will:

(1) Provide necessary logistical and administrative support within maneuver area for all Air Force units participating in this exercise.

(2) Prepare necessary logistics and administrative plans as requested by Commanding General, Tactical Air Force.

(3) Submit to Headquarters, Continental Air Command, logistics requirements which are beyond the capabilities of Fourteenth Air Force.

(4) Submit detailed budget estimate and justification to Headquarters, Continental Air Command, on Fourteenth Air Force units and Air Umpire Group.

(5) Train, equip, and make available, upon request of Commanding General, Tactical Air Force, required elements of those Fourteenth Air Force units assigned to this

Directive for the Implementation of Joint Army-Air Force Exercise, Fiscal Year 1950 - "Swarmer" (Contd)

exercise (paragraph 3, above).

(c) Furnish Commanding General, Tactical Air Force, for submission of movement requests to Headquarters, Continental Air Command, necessary information concerning participating Fourteenth Air Force units.

5. Direct communication is authorized between all addressees of this directive for planning purposes and execution of this exercise.

RESTRICTED

"SWARMER"

DEPARTMENT OF THE ARMY DEPARTMENT OF THE AIR FORCE

Washington 25, D. C., 10 December 1949

Directive for Joint (Army-Air Force) Exercise, FY 1950

1. Directive A Joint Army - Air Force exercise involving airborne landings, ground and tactical air operations, will be held in the Third Army and Fourteenth Air Force area, in April - May 1950.

2. Purpose

a. To provide training and experience in the operation of a joint maneuver headquarters.

b. To study the organization and operation of an airhead.

c. To develop aerial resupply procedures and techniques.

d. To train Army and Air Force units and staffs in the procedure, tactics, and techniques incident to air-ground and airborne operations.

e. To test and evaluate methods of close air support for airborne units.

f. To determine requirements for special equipment which may be substituted for equipment in the land tail of airborne units.

g. To test tactical application of new developments in weapons.

h. To evaluate training proficiency of participating units as a basis for prescribing further training for combat readiness.

3. Concept

a. That air attacks followed by an airborne landing by AGGRESSOR nation have created a state of war between AGGRESSOR and the United States.

b. That having gained local control of the air against the dispersed United States Air Force units, an airhead is established by AGGRESSOR in North Carolina.

c. That having concentrated air and ground forces under the command of the Commanding General, Tactical Air Force, and Commanding General, Third Army, the United States is able to cut off AGGRESSOR's supply line and check AGGRESSOR advance.

d. That a timely airborne operation by Joint United States Forces contributes to the eventual annihilation of AGGRESSOR forces in the airhead.

4. Participating Forces

a. United States Forces:

(1) Army: One airborne division and supporting units.

(2) Air Force: Seven Troop Carrier Squadrons.

(Same units used by AGGRESSOR)

One Fighter Group

Two Light Bomb Squadrons

One Tactical Reconnaissance Squadron

Elements of Tactical Control Group

Elements of Signal Battalion

One (1) Liaison Flight

Detachment SHORAN Beacon Unit

b. AGGRESSOR Forces

(1) Army: One Airborne Division (less one RCT and less one BCT) with supporting units.

AGGRESSOR GHQ units, Fort Riley, Kansas

(2) Air Force: Seven Troop Carrier Squadrons

One Fighter Group

One Tactical Reconnaissance Squadron

Elements of Tactical Control Group

c. Reserve Components

Employment of National Guard and Organized Reserve Corps units and personnel is authorized. Maneuver Commander's requirements will be coordinated by Chief, Army Field Forces, and by Commanding General, Continental Air Command.

5. Command Structure (Appendix A)

a. The maneuver director will be designated by the Chief of Staff, United States Air Force.

b. AGGRESSOR forces will be controlled by the Maneuver Commander. Joint Tactical Air Force - Army organization in the AGGRESSOR headquarters will be simulated. The Joint Operations Center will be the only element of the AGGRESSOR headquarters which will actively operate.

c. Unilateral components of the United States maneuver forces will be designated by respective services. The Maneuver Commander is authorized to prescribe the formation of a joint United States maneuver force or a joint AGGRESSOR Force and designate Commander thereof.

d. Chief, Army Field Forces, will designate the Chief Umpire for the Exercise. Commanding General, Continental Air Command, will designate the Deputy Chief Umpire.

6. Joint Maneuver Staff

a. The United States Air Force will provide personnel for the joint maneuver staff, to be organized as prescribed by Maneuver Commander.

b. Chief, Army Field Forces, will issue necessary orders to Army Commanders for provision of Army personnel required for the joint maneuver staff as prescribed by Maneuver Commander.

7. Responsibilities

a. Maneuver Commander is responsible for the overall conduct and planning of the exercise. His activities will include:

(1) Establishment, supervision, and training of umpire group.

(2) Establishment and supervision of Public Relations Bureau.

(3) Establishment and supervision of Visitors' Bureau.

(4) Tactical employment of AGGRESSOR forces.

b. Chief, Army Field Forces, is responsible for implementation of Department of the Army participation in the exercise.

c. Commanding General, Third Army (under coordination and supervision of Chief, Army Field Forces) will be responsible for:

(1) Provision of necessary housing and facilities for the joint maneuver headquarters.

(2) Administrative and logistical support of the Army maneuver forces and umpire group.

(3) Procurement and distribution of maps for all participating Army units.

(4) Provision of personnel for the Air-ground operations section of the United States Forces Joint Operations Center.

(5) Administration of special field exercises funds for the Army elements of the exercise.

d. Commanding General, Continental Air Command, will be responsible for:

(1) Provision of Air Force units outlined in paragraph 4.

(2) Designation of agencies responsible for the logistical and administrative support of participating Air Force units and umpire group.

(3) Designation of agencies responsible for submission of requirements for Air Combat Maneuver Funds and umpire group.

(4) Designation of agencies responsible for the production of the Air Operation Plan.

e. Commanding General, Tactical Air Force, will be responsible for:

(1) Tactical employment of maneuver United States Air Force units.

(2) Operation of the United States Forces Combat Operations Section of the Joint Operations Center, and supervision

of the Tactical Control System.

8. Intelligence

During preliminary planning stages, this exercise will be classified as restricted. As soon as necessary movement instructions have been issued to units, and on instructions of Maneuver Commander, security classification will be eliminated. For the play of the exercise intelligence problems will be incorporated in all phases. AGGRESSOR will be used to develop the enemy situation so that United States forces intelligence agencies may simulate operational conditions.

9. Communication

a. Maneuver Commander is authorized to call upon participating units for such personnel as may be required in the conduct of his activity.

b. Direct communication is authorized among the major commanders and the Chief, Army Field Forces, indicated herein.

10. Reports

Maneuver Commander will prepare reports covering the exercise, limited to essential facts.

BY ORDER OF THE SECRETARIES OF THE AIR FORCE AND ARMY:

/s/ S. E. Anderson
/t/ S. E. ANDERSON
Major General, U. S. Air Force
Director of Plans and Operations.

/s/ Clift Andrus
/t/ CLIFT ANDRUS
Major General, U. S. Army
Director of Organization & Training

FOREWORD

This manual will provide Air Umpires with pertinent Umpire rules and Damage Assessment Tables for easy reference.

These rules and instructions are provided as a standard and should not be dogmatically invoked when common sense and good judgement dictate the necessity for deviation, provided the spirit of the written directive is not violated.

The safety of participating personnel should be considered when invoking decisions contrary to published criteria.

THIS PAGE IS DECLASSIFIED IAW EO 13526

SYNOPSIS OF EXERCISE SWARMER

1. GENERAL

a. Exercise Swarmer is a joint Army-Air Force-Navy maneuver being held in the Camp MacKall-Fort Bragg area during the period 24 April to 8 May. It is planned to include the tactical air movement of an estimated 18,000 Army Airborne troops. It is, in the main, a controlled maneuver, control being exercised through an umpire organization, which also operates to maintain realistic combat situations. There is to be a minimum of assumed forces in the maneuver area proper.

b. The primary purpose of this maneuver is the study of problems involved in the establishment and maintenance of an airhead in the face of air and ground opposition; particularly, the capability of the USAF to defend troop and supply movements and necessary airfields from air attack and to also provide close support to the airborne troops in their ground battle.

c. Secondary purposes are:

(1) To provide training and experience in the operation of a joint headquarters.

(2) To develop procedures and techniques of aerial resupply.

(3) To train Army and Air Force units and staffs in the procedures, tactics, and techniques incident to Air-Ground and Airborne operations.

(4) To test and evaluate methods of close air support for Airborne units.

(5) To determine requirements for special equipment that may be substituted for the heavy non-air-transportable equipment in the "by-land" tail of airborne units.

THIS PAGE IS DECLASSIFIED IAW EO 13526

(6) To test tactical application of new developments in weapons.

(7) To evaluate training proficiency of participating units as a basis for prescribing further training for combat readiness.

2. SITUATION

a. General: A state of war exists between AGGRESSOR nation and the United States caused by invasions of the United States. AGGRESSOR, taking advantage of the normally scattered U. S. Armed Forces, has seized the Florida peninsula, and has invaded North Carolina by amphibious and airborne operations, generally from the coast in the Wilmington area; he is capable of an added invasion either into Georgia, or from the eastern Gulf. Third Army and Tactical Air Force have concentrated forces to operate against the invader in the North Carolina area.

b. Special: U. S. Forces plan to establish an airhead within the invaded area, in the vicinity of Fort Bragg, for the purpose of cutting AGGRESSOR supply lines, stopping his advance to the north and west, and destroying the main elements of the AGGRESSOR forces. U. S. Forces from west of the Great Smoky Mts., are to seize the small, lightly defended, Camp MacKall airfield as a first air supply point, and drop airborne troops in three areas of the Fort Bragg reservation. Pope Air Force Base is the second objective of these ground troops, in order to gain a fully developed airdrome for air landing of additional troops, equipment and supplies. A third objective is the capture of the Fayetteville Airport (assumed, just south of the Reservation) that is being used as a supply point, by airlift, for

0243

the AGGRESSOR Forces.

3. TROOPS

a. U. S. Forces, Army

(1) 82nd Airborne Division

(2) 11th Airborne Division (reduced)

(3) One Liaison flight

b. U. S. Forces, Air

(1) 3 Fighter Groups: 4th: F86, 20th: F84, USMC: 2 Sqdns

(2) 3 Troop carrier Gps: 7 Squadrons: 1 Sqdn of 62d: C54, 314th: 1 Sqdn C82, 2 of C119, 316th: C82

(3) 1 Transport Group: MATS, 4 of 5 Sqdns: C54

(4) 1 Tac. Recon. Sqdn

(5) 1 Tactical Control Group (reduced)

(6) Air Bases at Shaw, Congaree, Langley, Oceana, and Charlotte (the last assumed, actually using Laurinburg-Maxton).

c. AGGRESSOR Forces, Army

(1) 15th Infantry, heavily reinforced

(2) 44th Tank Battalion

(3) One Liaison flight

d. AGGRESSOR Forces, Air

(1) 1 Fighter Group, 31st: 3 Sqdns F84, 1 Tac. Recon. Squadron

(2) Troop Carrier and Transport minor use of same units as U. S.

(3) Forces above Elements of a Tactical Control Group.

(4) Air Base assumed in the Wilmington area, actually using Langley.

4. Information:

a. Department of the Army and Department of the Air Force Joint (Army - Air Force) Exercise Fy 1950 dated 10 December 1948 directed that a joint exercise be conducted in the Third Army and Fourteenth Air Force area in April - May 1950. The purpose of the exercise is:

(1) To provide training and experience in the operation of a maneuver Headquarters.

(2) To study the organization and operation of an airhead.

(3) To develop aerial resupply procedures and techniques.

(4) To train Army and Air Force Units and Staffs in the procedure tactics, and techniques incident to air-ground and airborne operations.

(5) To test and evaluate methods of close Air support for Airborne units.

(6) To determine requirements for special equipment which may be substituted for equipment in the land tail of airborne units.

(7) To test tactical application of new developments in weapons.

(8) To evaluate training proficiency of participating units as a basis for prescribing further training for combat readiness.

b. The Chief Umpire was appointed by the Maneuver Commander Per Ltr Order No 122 Headquarters Sixth Army, Dated 16 Jan 50. Umpires for ground and Air were subsequently appointed by the department of the Army and Air Force.

c. This operation plan is based upon Chief Umpire Command Memorandum, dated 24 Feb 1950 and covers the operations of the Air Umpire Group in connection with Joint Exercise (Swarmer).

d. Enemy forces: None

e. Friendly forces: None

f. For details of forces to be umpired and observed see, Par 3b(4) GENERAL PLAN FOR TRAINING EXERCISE SWARMER.

5. Mission: The Air Umpire Group will;

a. Procure Personnel and equipment for the group.

THIS PAGE IS DECLASSIFIED IAW EO 13526

b. Organize and train the group.

c. Administer the group.

d. Prepare Air Umpire Rules and instructions for all Air Operations.

(1) Air Umpire rules to be guided by FM 105-5, FM 30-101, FM 30-103, FM 30-102, FM 31-35, FM 71-30 USF 79A, USF 79(A)-1

(2) Air Umpire rules to be completed by 10 March 1950.

e. Umpire Invasion and Aggressor Force air elements during all phases.

(1) Umpire Air Planning.

(2) Umpire establishment and functioning of Air Force elements at all bases used in the maneuver.

(3) Umpire Air Operations and action.

(4) Pay particular attention to preparation, movement, control, coordination, and protection of airborne and troop carrier elements.

f. Reporting and Assignment Dates for Umpires.

(1) All Air Umpires will report to Ft Bragg, North Carolina for training not later than 25 March 1950.

(2) All Air Umpires will be in place with units to be umpired not later than 10 April 1950.

g. Upon completion of the exercise submit a report of Air Umpire activities in sufficient detail to permit the Chief Umpire to evaluate performance of all Air elements.

h. Execute other functions as directed.

6. Tasks:

a. D/CAU operations will:

(1) Assemble and coordinate the rules and regulations under which SAUS operates.

(2) Direct the planning, training and operational activities of all Air Umpires.

(3) Conceive, prepare, and monitor the operational and intelligence requirements for the Air Umpires Manual for all air elements.

b. DCAU Personnel will:

(1) Perform personnel and administration duties (to include adjutant functions) for Headquarters SAUS.

(2) Conceive, prepare, and monitor the personnel and administration requirements for the Air Umpire Manual.

c. DCAU/Communications will:

(1) Establish and maintain communication facilities for SAUS.

(2) Conceive, prepare, and monitor the communications requirements for the Air Umpire Manual.

d. DCAU Materiel will:

(1) Perform materiel function for SAUS to include individual Air Umpires during the training period.

(2) Conceive, prepare, and monitor the logistical requirements for the Air Umpire Manual.

7. Administration and Logistics: See Annexes C and D to this plan.

8. Command and Communications.

a. Communications in accordance with Air Umpire Communications plan, Annex B to this plan.

b. Chief Air Umpire will be located as follows:

(1) Headquarters SAUS, Fort Bragg North Carolina, 15 February 1950 - 10 April 1950.

(2) Headquarters SAUS, Camp McKall North Carolina, 10 April 1950 - 8 May 1950.

(3) Headquarters SAUS, Fort Bragg, North Carolina, 8 May 1950 - 15 May 1950.

AIR UMPIRE SECTION (SWARMER)
Fort Bragg, North Carolina

Annex "A"
To Chief Air Umpire
Operations Plan
1-50

27 February 1950

RULES AND INSTRUCTIONS

ANNEX A

Purpose:

1. The purpose of this annex is to prescribe those rules and instructions necessary for Air Umpires to properly judge and observe the effectiveness of air operations in joint service operations; examine the validity of current techniques and procedures for joint umpire operations, and to accumulate knowledge and data concerning the principles governing a joint air support-airborne-troop carrier operation; evaluate capabilities of new items of equipment for their suitability in joint operations.

Coordination of Air and Ground Umpires:

2. In order that the Air Umpire Section proceeds on a coordinated basis the following outline will be utilized as a guide:

a. The Air Umpire Section will umpire the following:

(1) All air-to-air combat. Damage will be assessed in accordance with damage assessment tables, Section VII, this annex.

(2) All troop carrier responsibilities in the Airborne assault.

(3) Effectiveness of each air attack, both air-to-air and air-to-ground expressed in percentage. Effectiveness of attack will be determined in general by:

a. Tactics employed.

b. Types of formation flown.

c. Overall operation of the unit with regard to such matters as briefings, take off and join up, ability to operate in existing weather conditions, and whether or not the proper target was actually located and attacked.

(4) All aerial reconnaissance missions, both visual and photographic.

(5) Damage to airbases and aircraft on air bases by hostile attack.

(6) Damage inflicted on attacking aircraft by air base defense.

(7) Operation of Tactical Air Control Center and Subordinate Echelons with respect to overall effectiveness in controlling aircraft, passing on necessary information, detecting incoming hostile air attacks, and integration of communications with ground anti-aircraft defense in the assault area.

b. The Ground Umpire Section will umpire the following phases of air operations:

(1) The preparation for Emplaneing in aircraft, the actual "jump" and operations of the airborne unit thereafter.

(2) Damage to all ground targets by attacking aircraft.

(3) Damage to attacking aircraft by ground anti-aircraft defenses.

3. Coordination of Logistics Umpiring.

a. Planning Phase.

(1) All Air Umpires:

a. Judge the appropriateness of directives issued to bring required items for air supply to loading points.

b. Judge concurrently with the Ground Umpires, the preparation of loading plans of Air Force units with Airborne units. Also, observe the adequacy of aircraft provided and combat loading. Determine further if these plans support the tactical requirements for the units.

b. Preparation Phase.

(1) All Air Umpires:

Determine the completeness and adequacy of the Air Force units preparations for the maneuver and corrective action taken as a result of discrepancies discovered.

c. Assault Phase.

(1) All Air Umpires

Observe handling of air force materials to determine that appropriate procedures are followed in handling equipment or cargo by all air force organizations and that delivery schedules are met in order to meet tactical commitments.

d. During free phases, the Invasion and Defense Forces will operate under their respective plans to carry out their assigned missions. Both Invasion and Defense Forces will be umpired. In the event that opposing actions are such that no contacts will result, the Chief Umpire, with the concurrence of the Maneuver Commander, will take such action as he may deem desirable to keep contact between the opposing forces.

e. During controlled phases, the Defense Force will be employed in general conformance with FMs 30-101, 30-102, 30-103, 30-104 insofar as is necessary to insure adequate training of the Invasion Force. Basically, the Defense will be planned, organized and executed under the supervision of the Defense Commander. The Defense and Invasion Plans will be studied by the Chief Air Umpire and Control Plans prepared to insure inclusion of training. These control plans will control air missions and action by the Defense to insure meeting training objectives. Control plans will be consolidated by the Chief Umpire. After approval by the Maneuver Commander, control plans will be forwarded to the Defense Commander for execution. Local adjustments may be made to control plans during the execution phase by the Chief Air Umpire as may be required for successful execution of the exercise. The Chief Umpire will be kept informed of control plan changes. During controlled phases, the Invasion Force will be umpired, the Defense Force will be observed, and casualties assessed as appropriate.

f. The consolidated control plan will be distributed to the Maneuver Commander, Defense Commander and Umpire Group only, prior to completion of exercise.

4. Phases of Air Umpiring.

a. Each Umpire will judge certain phases of air operations for the purpose of this exercise. Where damage assessment is made by other than Air Umpires, the Air Umpire will make an evaluation of the attack and include it in the Air Umpire's final report to the Chief Umpire.

b. Ground and Air Umpires will judge their respective components throughout airborne planning and execution. Casualties to aircraft and crews will be assessed by Air Umpires, and casualties to airborne elements will be assessed by Ground Umpires, if appropriate. Any casualties to airborne elements will be restored prior to reaching of drop zone.

c. Coordination of prisoner exchange will be as prescribed by Chief Ground Umpire.

d. Coordination of "out of action" will be as prescribed by Chief Ground Umpire for Army equipment, and will be as prescribed by Chief Air Umpire for aircraft and related aviation equipment in Section VII.

0256

e. Each Umpire Group will judge and observe communications within its scope of umpiring. See Annex B .

5. Umpiring Air Operations.

a. All air-to-air operations will be judged by air umpires.

The following will be considered in evaluating air operations generally:

(1) Tactics employed.

(2) Types of formation flown.

(3) Gaining and maintaining air superiority.

(4) Escort and defense of troop carrier.

(5) Overall operation of the unit with regard to briefings, communications, takeoff and join up, and ability to operate in existing weather conditions.

(6) Operation as directed by the Tactical Air Controller.

(7) Relative performance, armament.

b. Interceptions.

Interceptions will be judged on the following:

(1) Element of surprise.

(2) Altitude Advantage.

(3) One pass only by attackers (There will be no melees or Dog Fights).

(4) Whether or not the proper target was actually located and attacked.

c. Escort Missions will be judged on the following:

(1) Joint planning.

(2) Rendezvous.

(3) Tactics employed.

THIS PAGE IS DECLASSIFIED IAW EO 13526

4

d. Combat Air Patrol will be judged on the following:

(1) Ability to follow directions from the Air Controller.

(2) Receipt of sufficient instructions from the Air Controller to make an interception.

(3) Tactics employed.

e. Air-to-surface operation will be judged by the following:

(1) Joint planning.

(2) Tactics employed.

(3) Types of formations flown.

(4) Overall operation of the unit with regard to briefings, critiques, takeoff and join up, ability to operate in existing weather conditions.

f. Deep and Close Air Support will be judged by the following:

(Damage assessment by ground umpires, except attacks on air installations).

(1) Operation as directed by the Tactical Air Controller.

(2) Element of surprise.

(3) Correct time over target.

(4) Whether or not the proper target was actually located and attacked.

(5) Type of attack and accuracy resulting.

(6) Proper armament.

g. Troop Carrier missions will be judged on the following:

(1) Joint planning as to selection and preparation of route to drop zone.

(2) Coordination with fighter escort.

(3) Joint training.

0258

THIS PAGE IS DECLASSIFIED IAW EO 13526

(4) Aerial resupply and evacuation of wounded.

(5) Tactics employed.

(6) Types of formation flown.

(7) Overall operation of the unit with regard to briefings, take-off and join up and ability to operate in existing weather conditions.

(8) Whether or not the proper drop zone was reached and the jump properly performed.

(9) Return route and tactics employed.

h. Aerial reconnaissance missions will be judged on the following:

(1) Joint planning.

(2) Preparation.

(3) Results of visual reconnaissance.

(4) Results of day photographic reconnaissance.

(5) Results of night photographic reconnaissance.

(6) Dissemination of information gained on the mission.

(7) Whether or not the reconnaissance covered the objective or proper target.

i. All simulated operations will be within the limits as established by the Maneuver Commander and will be judged by Air Umpires in the same manner as an actual action:

(1) When aircraft are dispatched on a simulated mission, a like number of the same type will be grounded for the same period of times that it would take to complete the mission and return to home base and re-service.

(2) Damage will be assessed to both sides in accordance with the appropriate damage assessment tables.

(3) Aircraft grounded as a result of simulated operations may be utilized for flights which are not part of the maneuver.

(4) Aircraft are not subject to capture. They are only subject to simulated destruction.

6. Assumptions (To be announced by Maneuver Commander, at a later date.)

7. Decisions of Air Umpires:

a. Since the primary purpose of this exercise is to provide the maximum training for all personnel and units involved, the Air Umpires will be guided in rendering decisions on assessment of damage as outlined in section VII, Damage Assessment Tables.

b. It is desired that competition and decisions creating a sense of victory or defeat be avoided between the participating units in favor of promoting combined service training.

c. Air Umpires will make every effort to familiarize themselves with the training objectives of the other services.

d. The intent and spirit of unification of the services must be adhered to through close cooperation and understanding of mutual problems.

e. When existing umpire rules require amplification, the approved doctrines of the various services may be employed as guides. In the interest of using newly-developed umpire rules or methods based on recent exercises, modifications may be based upon reports and recommendations of these exercises where applicable.

f. Air Umpires will be assigned to units but are not required to be a part of the unit to which assigned. An officer designated to umpire his own unit will perform his duties impartially. His reports are not subject to review by any officer of the unit of force to which he is assigned.

g. All unit umpires will conform to umpire rules and procedures; however, units may call on umpires for decisions when needed, or for clarification of decisions already made.

8. <u>Air Base.</u>

a. The following Air Bases will utilized during the exercise as indicated:

	For the Defense	For the Invasion Forces
Pope AFB	X	X
Congaree AFB		X
Langley AFB	X	
Shaw AFB		X
MacKall AFB		X
Oceana NAS		X

0260

Campbell AFB

Laurinburg-Maxton AFB

9. Distinguishing markings of Aircraft.

To be announced by Maneuver Commander.

10. Security:

a. All classified material will be handled in accordance with the provisions of:

(1) JANAP 122

(2) Air Force Regulation 205-1

(3) Command Security Manuals and instructional documents of various crypto systems employed by using agencies.

b. If maneuver play dictates, orginators of correspondence, dispatches, and documents for use in Exercise SWARMER will designate two security classifications for materials prepared.

c. On correspondence and documents the maneuver classification will be shown below the actual classification. For Example:

RESTRICTED

SWARMER TOP SECRET SWARMER

d. In the texts of dispatches the words Swarmer SECRET (or other classification designated) will be included to show the maneuver classific tion. However, the actual classification will govern the necessary handling and servicing of dispatches and transmission of documents between headquarters.

e. Air Umpires will not divulge any Swarmer Umpire information to either the Invasion or Defense Forces.

11. Psychological Warfare:

a. Both the Invasion Force and Defense Force Commanders may use psychological warfare during the Swarmer exercise. Plans should include all measures that would be appropriate and practicable in actual war, but those measures not to be executed (simulated) should be stipulated as such.

b. Actual techniques employed will be confined to those of the Tactical Psychological Warfare; the normal civil life of the maneuver area must not be disturbed.

c. In order to avoid actual results that would be harmful to United States interest, the following policies are set forth to govern the execution of planned measures.

(1) No actual psychological warfare measures will be executed that will offend any group of United States citizens on account of race, religion, political or geographical background.

(2) No actual psychological warfare measures will be planned or executed that will intimate that opposing forces represent or resemble any nation other than the United States or "Aggressor".

(3) No actual psychological warfare measures will be executed that will tend to cause ill-feeling among branches of the U.S.Armed Forces.

(4) Psychological warfare themes aimed at the morals of opponents may be planned, but not included, in propaganda. Air Umpire these activities will be observed and commented in Air Umpire reports.

12. Intelligence

a. The Maneuver Commander will act as overall coordinating authority in matters pertaining to intelligence.

b. The Invasion and Defense Commanders will obtain intelligence through agencies normally available to themselves and their component commanders.

C. The Invasion and Defense Forces will consist mainly of actual Units assigned, but may include simulated units determined by the Maneuver Commander (after consultation with Invasion and Defense Commanders) to be necessary in order to insure meeting the training requirements set forth by the joint Chiefs of Staff.

13. Administrative, Logistical and Medical:

Air Umpires will observe and report on those logistical, fiscal, administration and medical aspects of the exercise that have a direct bearing on the effectiveness of the operational unit in combat in accordance with check-list provided by the Chief Air Umpire.

0262

Umpires of all echelons will enforce supply discipline to insure conservation, care, and preservation of supplies and equipment.

14. Uniforms, Air Umpires:

a. Air Umpire will wear the prescribed Air Force Uniforms.

b. Distinctive insignia is to be prescribed later.

THIS PAGE IS DECLASSIFIED IAW EO 13526

Appendix 1 to Annex A
Chief Air Umpire Operation Plan 1-50

1 March 1950

Responsibilities of Air Force Umpires

1. Invasion and Defense Force Umpires will be responsible for accomplishing the following:

a. Observe, evaluate and report on staff and command functions of the Force to which assigned. This will include planning, operations, intelligence, administration and logistics.

b. To receive, evaluate and consolidate reports from subordinate Umpires for preparation and forwarding to the Chief Air Umpire.

c. Organize, supervise and monitor umpires of the Force's subordinate elements to provide umpire coverage of all phases of the maneuver and to compile data concerning the performance of these units.

d. Perform other functions as directed by The Chief Air Umpire.

2. Airdrome Umpires will be responsible for accomplishing the following:

a. Organize, supervise and monitor the activities of the Wing, Group and Squadron Umpires.

b. Assimilate, consolidate and forward information and/or reports received from subordinate umpires to the Force Umpire.

c. Establish himself in an accessible location on the airdrome in order to facilitate the efficient functioning of the Umpires.

d. Assess damage inflicted to airdrome facilities and/or aircraft operations.

e. Prepare final umpire reports for submission to the Force Umpire with the assistance of subordinate umpires.

f. Perform other functions as directed by the Force Umpire.

3. Wing Umpire will be responsible for accomplishing the following:

a. Observe, evaluate and report on staff and command functions of the Wing to which assigned. This will include

THIS PAGE IS DECLASSIFIED IAW EO 13526

planning, operations, intelligence, administration and logistics.

b. To receive, evaluate and consolidate reports from subordinate Umpires for preparation and forwarding to the Airdrome Umpire.

c. Organize, supervise and monitor umpires of the subordinate element to provide umpire coverage of all phases of the Wing's part in the maneuver and to compile data concerning the performance of these units.

d. Assist Airdrome Umpire in preparation of final umpire report.

e. Perform other functions as directed by the Airdrome Umpire.

4. Group Umpires will be responsible for accomplishing the following:

a. Observe, evaluate and report on staff and command functions of the Group to which assigned. This will include planning, operations, intelligence, administration and logistics.

b. Direct, supervise and coordinate subordinate umpires in order to provide adequate coverage of all phases of the maneuver and to compile data concerning the performance of these units.

c. Assimilate information and reports from subordinates for submission to the Wing Umpire.

d. On Group missions, assess aircraft damage in accordance with damage assessment tables within his sphere of responsibility.

e. Perform other functions as directed by the Wing Umpire.

5. Squadron Umpire will be responsible for accomplishing the following:

a. Observe, evaluate and report on staff and command functions of the Squadron to which assigned. This will include planning, operations, intelligence, administration and logistics.

b. Appoint, instruct, direct, supervise and coordinate organic umpires in order to provide adequate coverage of all phases of the Squadron's part in the maneuver and to compile data concerning the performance of the unit.

c. Prepare reports for submission to the Group Umpire.

d. Accompany aircraft on Squadron missions within his reasonable capabilities. Requirements exceeding his capabilities will be met by the selection of organic air umpires.

e. Perform other functions as directed by the Group Umpire.

6. Tactical Air Control Center Umpire will observe, rate and report to the Force Umpire on the TACC and Tactical Air Control Group to which assigned on the following:

a. Ability of Unit to clearly present a continuous and timely representation of the air picture.

b. Ability of Unit to efficiently utilize organic communication facilities and equipment.

c. Ability of Unit to identify all friendly aircraft through knowledge of flight plans, radar, data, and other related information.

d. Ability of Unit to utilize information of air situation to effectively employ fighter aircraft and AAA.

e. Ability of Unit to safeguard equipment and personnel.

f. Ability of the Tactical Air Control Group to perform its primary mission. This mission is to observe, evaluate and report on staff and command functions of the TACG to which assigned. This will include planning, operations, administration and logistics.

7. Tactical Air Direction Center Umpire will observe and report to the Tactical Air Control Center Umpire on the following:

a. Ability of Unit to efficiently operate organic radar and IFF equipment, reporting data [illegible] with minimum time delay according to Standard Operating Procedure.

b. Ability of Unit to clearly present a continuous and timely presentation of the air picture.

c. Ability of Unit to utilize air information to control combat forces.

d. Ability of Unit to efficiently utilize organic communication equipment.

e. Ability of Unit to safeguard equipment and personnel.

8. Air Liaison Officers: There will be provided two Air Liaison Officers (U.S. Forces, Aggressor Force) who will be responsible to the Chief Air Umpire. They will perform the following duties:

0266

a. U.S. Force Liaison Officer will maitain liaison with Army Ground Forces and Aggressor Liaison Officer, and advise him of location, disposition and plans of the United States Forces.

b. Aggressor Force Liaison Officer will maintain liaison with United States Force Liaison Officer and advise him of location, disposition and plans of the Aggressor Force. This information will not be divulged to the U. S. Forces Commander unless specifically directed by the Chief Air Umpire.

c. The Aggressor Force Liaison Officer will maintain liaison with the Aggressor Force Commander and keep him informed of the U. S. Forces dispositions and plans.

d. Force Liaison Officers will maintain contact with the Chief Air Umpire at all times and will keep him informed of Air Force and Army dispositions.

e. Force Liaison Officers will perform such other duties as may be directed by the Chief Air Umpire from time to time.

9. Radar Umpire Officers will be responsible for accomplishing the following:

a. Observe, rate and report on the functions of the radar site to which assigned. This will include interceptions, plotting, siting, condition of equipment and capabilities of operating personnel. The latter will particularly include the recognition and action taken against electronic counter-measures.

b. Prepare reports for submission to the TACC Umpire.

c. Perform other functions as directed by the TACC Umpire.

10. Joint Operation Center Umpires will observe, rate and report to the Chief Air Umpire on the JOC to which assigned on the following:

a. Ability to coordinate staff and command functions, to include planning within the JOC.

b. Perform other functions as directed by the Chief Air Umpire.

11. Signal Battalion Umpire will observe, rate and report to the Force Umpire to include the following:

a. Ability to perform staff, command and operational functions. This will include planning, administration and logistics.

b. To review and evaluate the adequacy, and ability to perform the communication plan published by higher headquarters as regards the necessary provisions to accomplish the mission of the Signal Battalion.

c. Ability of Unit to efficiently operate organic communication equipment.

d. Ability of Unit to safeguard equipment and personnel.

12. Air Umpires at all echelons will be responsible for determining the degree to which participating organizations employ security practices in the preparation, transmission, reception, storage, recording and destruction of classified materials. Umpires will be guided by the provisions of Air Force Regulation 205-1 and JANAP 122.

THIS PAGE IS DECLASSIFIED IAW EO 13526

Appendix 2 to Annex "A"
CAU Operation Plan 1-50

27 February 1950

AIR AGGRESSOR CONTROL PLAN

1. Definition:

a. The Control Plan controls specific air action by the Aggressor Air Force in order to achieve training objectives.

2. Purpose:

a. The purpose of Control Plan is to substitute wartime unknown factors similar to those encountered in actual combat for known factors which are usual in peace-time maneuvers.

3. Concept:

a. The initiation of Air Operations rests with the Aggressor Air Forces and the least possible interference in planned missions is anticipated.

b. The responsibility of controlling such missions rests with the Chief Air Umpire in order to avoid violations of certain air concepts established by doctrine.

c. The primary purpose of this maneuver is to provide training for all participants, and the Control Plan will contribute in accomplishing this purpose. Furthermore it is highly desirable that maximum utilization be made of all aircraft in the maneuver without violating accepted concepts.

d. The Aggressor Control Plan will go in effect on the day the Invasion Forces achieve Air Superiority. The Chief Air Umpire will determine the date when Air Superiority has been achieved.

4. Operations:

a. After Air Superiority has been achieved, Aggressor Air Force will forward all contemplated missions to the Chief Air Umpire for approval and control as to their feasibility in the light of existing situations.

b. Defensive missions requiring spontaneous decisions will depend on Aggressor's capabilities and action of the opposition.

c. Offensive missions must be submitted six (6) hours in advance of execution.

d. In addition to Air Aggressor planned missions, the Chief Air Umpire may order specific missions. This may be done to exploit the flexibility of opposing Air Forces and provide the desired training for participants. All such strikes will be ordered as much in advance as practicable.

e. Planned air strikes may be changed by the Chief Air Umpire as the situation dictates, in order to achieve successful execution of the exercise.

f. The Chief Air Umpire will be kept informed of implementation of Control Plan.

g. Attached is numbered list of type strikes which may be ordered by the Chief Air Umpire when appropriate.

TYPES OF AIR STRIKES WHICH MAY BE ORDERED BY
CHIEF AIR UMPIRE DURING CONTROLLED PHASE

1	Fighter attack (s) on Troop Carrier Serial (s).
2	Fighter bombing, rocket, and strafing attack on U. S. Air Forces Bases.
3.	Fighter mission (s) in close support of Aggressor Ground Forces.

THIS PAGE IS DECLASSIFIED IAW EO 13526

Appendix 3 to Annex "A"
CAU Operation Plan 1-50

Air Umpire Visual Signals.

1. It is desired to develop the use of visual signals for Air Umpiring in order to reduce communications traffic.

2. Flying Air Umpires should encourage the use of Visual Signals in transmitting the percentage of effectiveness of an air strike to the flight leader. The Air Umpire will include such percentages in his report to the next higher Air Umpire echelon.

3. Flying Air Umpires are responsible for briefing flight leaders in the employment of visual signals.

4. Visual signals for indicating the percentage of effectiveness of an air strike will be transmitted by the Air Umpire if practicable. This may be accomplished by flying parallel to the flight leader and executing the applicable signal. A list of sample signals follow:

a. Mission complete failure - Dive the aircraft.

b. Mission 25% effective - Rock wings.

c. Mission 50% effective - Porpoise aircraft.

d. Mission 75% effective - Fishtail aircraft.

e. Mission 100% effective - Pull up into a steep climb.

(These signals may be revised if necessary)

5. At the completion of the exercise Air Umpires will submit the list of signals used and make recommendations as to their practicability for future exercises.

THIS PAGE IS DECLASSIFIED IAW EO 13526

Air Safety

1. Air Umpires will be completely familiar with USAF and Naval fl- flying safety regulations. Reports of Violations will be made in Air Umpire Reports.

2. In addition the following safety rules will be observed, and any violations will be reported by Air Umpires:

a. Jet aircraft will not attack other aircraft closer than one thousand (1,000) feet. Propeller - driven aircraft will not attack other aircraft closer than five hundred (500) feet.

b. Individual dog-fighting between aircraft is prohibited.

c. Only one pass will be allowed in any one engagement.

d. Transport type aircraft will not be attacked. Intent to attack may be signified by a parallel pass with a minimum of one thousand (1,000) feet clearance.

e. Unnecessary low or "hot shot" flying.

3. Air Umpires will insure that they are completely familiar with the established Search and Rescue procedures.

4. Airdrome Umpires will check the following:

a. Adequacy of crash fire-fighting equipment.

b. Smoking near parked aircraft.

c. Fire guards when aircraft is started.

d. Fast and/or careless taxiing.

e. Check for control of takeoff, landing and parking of aircraft.

f. Protection of troops from propellers.

g. Any laxity - protection of personnel and equipment.

h. Provisions for care of actual and simulated casualties.

5. Flying Umpires where applicable will check:

a. If troops and passengers are instructed in wearing of parachute and wearing of safety belts.

0273

THIS PAGE IS DECLASSIFIED IAW EO 13526

b. If smoking regulations are enforced in aircraft.

c. On any violations of safety regulations or dictates of common sense affecting safety.

THIS PAGE IS DECLASSIFIED IAW EO 13526

Appendix 5 to Annex "A"
CAU Operation Plan 1-50

Damage Assessment

1. Damage assessment will be in accordance with tables contained in this Handbook:

a. Air to air:

(1) Joint planning/training.

(2) Overall tactics including formation(s), axis of of attacks(s), element of surprise, altitude advantage, air superiority measures, relative aircraft performance, etc.

(3) Unit operational readiness/effectiveness including briefing(s), communications, takeoff/join-up, existing weather capabilities, mission results, critique(s), etc.

(4) Compliance with Tactical Air Controller instructions and sufficiency of such directions. (Proper target actually located and attacked at time specified, with armament required).

(5) One pass only by attacker(s) (No melees or dog fights).

b. Air to Surface:

See a (1), (2), (3), and (5) above.

c. Escort:

(1) See a (1), (2), (3), and (5) above.

(2) Rendezvous.

(3) Troop Carrier Serial(s) defense.

d. Combat Air Patrol (CAP):

See a (2), (3), (4), and (5) above.

e. Interception:

See a (2), (4), and (5) above.

f. Night/All Weather Interceptions:

See a (2), (3), (4), and (5) above.

THIS PAGE IS DECLASSIFIED IAW EO 13526

(Damage assessment made by control center umpire(s).

g. Deep/Close Air Support:

See a (1), (2), (3), and (4) above.

(Damage assessment made by Army Umpires except upon air installations).

h. Troop Carrier:

(1) See a (1) above.

(2) Selection and preparation of route(s) to objective(s).

(3) Air movement of airborne troops.

(4) Fighter escort coordination.

(5) Air supply and evacuation.

(6) See a (2) and (3) above.

i. Air Reconnaissance:

(1) See a (1), (2), and (3) above.

(2) Information dissemination procedures.

(3) Whether pilots adjudged casualties and furnished mission report(s)/photograph(s) to unit(s).

j. Simulated Operations:

(Will be within limits established by Maneuver).

Commanded and umpired in same manner as actual action(s).

2. Aircraft Ruled Out of Action:

a. Aircraft that are part of a formation, ruled out of action by Air Umpires, will continue on with the remainder of the formation, but will not be counted as attacking the target for damage assessment purposes.

b. Single aircraft (including liaison type and night intruders) ruled out of action by appropriate umpires will return to base immediately when so instructed by the umpire.

c. Aircraft ruled out of action will be available as replacements upon return to home base only after having beem completely serviced.

d. Aircraft on the surface, ruled out of action due to bombing attacks on the airdrome, will be considered out of action for the same period of time that the airdrome is closed and/or ruled out of action in accordance with damage assessment tables X and XI.

e. Aircraft on the surface, ruled out of action due to strafing attacks, will be available as replacements in thirty (30) minutes elapsed time after termination of attack.

(See Damage Assessment Tables VII and VIII).

f. Aircraft on the surface, not damaged by strafing attacks, (Damage assessment Tables VII and VIII), will be grounded only for the time interval that airdrome is closed in accordance with Damage Assessment Table IX.

g. Crews of out-of-action aircraft will not divulge any information concerning flight upon return to base, and will maintain radio silence for the out-of-action period except in case of emergency.

Inclosure 2
to Appendix 5
Annex "A"
CAU Oper
Plan 1-50

27 February 1950

DAMAGE ASSESSMENT

ANTI-AIRCRAFT VS AIRCRAFT

1. a. GENERAL: Aircraft lost as a result of anti-aircraft fire will be calculated by selecting the proper loss, (that is, the loss shown for the number of aircraft and number of batteries effective), in the basic loss tables as shown in Table 1 and by correcting this figure as shown in subsequent tables.

b. Effectiveness of Guns:

The table of basic aircraft loss (Table 1) to heavy anti-aircraft artillery is calculated on the assumption that all guns of all batteries are fully effective. If the effectiveness of four batteries has been determined by the AAA Umpire to be .25, .80, 1.00 and .50, add these figures. The answer (2.55) gives the number of batteries to consider for a collected basic loss number. When anti-aircraft artillery is not physically present, the penalties on batteries should be disregarded, and the basic loss facters in Tables 1 and 7 will be used.

TABLE 1 - BASIC AIRCRAFT LOSS TO GUNS ("X" VALUE)

Number of Aircraft	Number of 90mm Batteries Effective					
	1	2	3	4	5	6
	Aircraft Losses					
1	0.30	0.67	1.00	1.00	1.00	1.00
2	.30	..67	1.00	1.33	1.50	2.00
3	.30	.75	1.00	1.50	1.87	2.25
4	.40	.80	1.00	1.50	2.00	2.40
6	.42	.90	1.20	1.50	2.00	2.40
8	.48	..96	1.20	1.60	2.40	2.80
9	.56	1.00	1.35	1.80	2.70	3.15
12	.60	1.20	1.80	2.40	3.00	3.60
16	.80	1.60	1.92	2.72	3.20	4.00
24	.96	1.68	2.40	3.12	4.08	4.80

NOTES:

If only a fraction of a battery is effective, interpolate between batteries. Example: 3.5 batteries effective against 12 attacking aircraft result in the loss of 2.10 aircraft $\frac{(1.80 + 2.40)}{2} = 2.10$.

0279

c. Altitude ("A" Factor)

Calculation of rounds fired and accuracy of rounds result in the following corrections (Table 2)

TABLE 2 - ALTITUDE ("A" FACTOR)

Altitude	"A" Factor
3,000	0.70
6,000	.78
9,000	1.00
12,000	.74
18,000	.17
20,000	.018

d. Speed of Aircraft (S" Factor)

The corrections to be applied to the losses due to speed of aircraft is shown in Table 3.

TABLE 3 - SPEED ("S" FACTOR)

Speed of Aircraft	"S" Factor
180	1.33
200	1.20
220	1.09
240	1.00
260	.92
280	.86
300	.80
320	.70
400	.50
500	.30

e. Evasive Action ("V" Factor)

The table of basic loss (Table 1) assumes that no evasive action is taken. For loss reduction due to evasive action, factors listed in Table 4 will be employed.

TABLE 4 - EVASIVE ACTION ("V" FACTOR)

Evasive Action	"V" Factor
Evasive Action	0.30
No Evasive Action Employed	1.00

NOTE:

Evasive action is credited if the attacking aircraft is climbing, diving or turning, to avoid anti-aircraft fire.

f. Formation ("F" Factor)

The table of basic loss assumes a tight formation. For loss reduction due to formation, correction factor "F" (Table 5) will be employed.

0280

THIS PAGE IS DECLASSIFIED IAW EO 13526

TABLE 5 - FORMATION ("F" FACTOR)

FORMATION	"F" FACTOR
Tight	1.00
Loose	.85
Very Loose	.70

NOTES:

(1) Tight Formation: The interval between aircraft does not exceed a lateral distance of one wing span or a longitudinal distance of one aircraft length.

(2) Loose Formation: The interval between aircraft varies from two to four wing spans and aircraft lengths.

(3) Very Loose: The interval between aircraft exceeds four wing spans and aircraft lengths.

g. Subsequent Runs ("R" Factor)

Table of Basic Loss assumes a single run through the zone of fire. Additional runs will be assessed by applying the factor "R" (Table 6) to losses determined for the first run.

TABLE 6 - SUBSEQUENT RUNS ("R" FACTOR)

Run	"R" Factor
First Run (No Warning)	0.50
First Run (Prior Warning)	1.00
Second Run	1.50
Third Run	2.00

(1) If the formation attacks in waves, which are so widely separated that each wave may be engaged by the entire anti-aircraft artillery defense, the formation will be considered as making two or more runs, and the losses increased on the subsequent runs.

(2) When anti-aircraft artillery units are actively participating in a maneuver, it will be considered that prior warning has been received if the target is engaged before it reached the perimeter of the anti-aircraft artillery defense.

h. Application of Basic Loss Table and Corrections

(1) Losses for a particular attack may be determined by the following formula:

Loss = ASVFRxX

0281

Example: 12 aircraft flying at 6000 feet and 220 MPH in loose formation, employing evasive action, attack on Airdrome where there are five (5) batteries of 90mm guns of which only 4½ batteries are effective. Prior warning has been received.

X =	2.7	(From Table 1)
A =	.78	(From Table 2)
S =	1.09	(From Table 3)
V =	.60	(From Table 4)
F =	.85	(From Table 5)
R =	1.00	(From Table 6)

Loss = .78X 1.09 X .60 X .85 X 1.00 X 2.7 = 1.17 Aircraft. The loss of one aircraft will be assessed.

(2) Value of "X" in basic loss table may **EXCEED** 100 percent of actual aircraft. If final answer exceeds 100 percent of aircraft, 100 percent loss will be assessed.

(3) If the entire formation makes a second run over the target, the number of aircraft against which losses will be assessed will be the net number of remaining after the first run.

2. Losses Due to Automatic Weapons:

The table of basic loss (Table 7) due to automatic weapons has been compiled with certain characteristics of aircraft, automatic weapons, guns/battery, etc; (FM 105-5) being assumed. A 40mm gun is considered equivalent in firepower to a quadruple mount cal. .50 machine gun. Losses will be calculated from the basic loss tables and corrections made in the same manner as for the 90mm anti-aircraft guns, using the formula: Loss = ASVFRxX. Losses of aircraft to Automatic Weapons will not be assessed unless such aircraft are at an altitude of 6000 feet (above terrain or below.

a. Effectiveness of Automatic Weapons:

When the number of batteries which are effective against a flight of aircraft has been determined by a Ground Umpire, aircraft losses may be calculated by means of loss tables.

b. Basic Loss Table for Automatic Weapons:

Table 7 indicates the basic loss of aircraft ("X" Value) to automatic weapons.

TABLE 7 - BASIC LOSS TO AUTOMATIC WEAPONS ("X" VALUE)

Number of Aircraft	Number of Batteries Effective					
	1	2	3	4	5	6
	Aircraft Losses					
1	1.0	1.0	1.0	1.0	1.0	1.0
2	1.50	2.0	2.0	2.0	2.0	2.0
3	2.5	3.0	3.0	3.0	3.0	3.0
4	3.0	4.0	4.0	4.0	4.0	4.0
6	3.2	5.0	6.0	6.0	6.0	6.0
8	3.5	6.0	8.0	8.0	8.0	8.0
9	3.5	6.0	8.0	9.0	9.0	9.0
12	3.5	6.0	8.0	9.5	11.0	12.0
16	3.5	6.5	8.5	10.0	11.5	14.5
24	4.0	7.0	9.0	10.0	12.0	15.0

c. Altitude Correction ("A" Factor)

Calculation of r-unds fired and average ranges result in the foll wing corrections for altituc : ("A") (Table 8) to be made, due to altitude of the attack:

TABLE 8 ALTITUDE ("A" FACTOR)

Altitude (FT)	"A" Factor
200	0.25
500	.33
1,000	.61
1,500	.67
2,000	1.00
2,500	.88
3,000	.58
3,500	.48
4,000	.29
4,500	.24
5,000	.13
5,500	.10
6,00	.07

d. Speed Correction ("S" Factor)

The correcti ns f und in Table 9 will be made to basic loss table for the speed of the attacking aircraft.

0283

THIS PAGE IS DECLASSIFIED IAW EO 13526

TABLE 9 - SPEED ("S" FACTOR)

Speed of Aircraft (M P H)	"S" Factor
180	1.40
200	1.25
220	1.12
240	1.00
260	.90
280	.83
300	.78
320	.70
400	.40
500	.15

e. Evasive Action ("V" Factor):

When it is discernible that the attacking aircraft are maneuvering to avoid anti-aircraft fire, evasive action will be credited.

Corrections found in Table 10 will be made to Basic Loss Table for evasive action taken:

TABLE 10 - EVASIVE ACTION ("V" FACTOR)

Evasive Action	"V" Factor
Evasive Action	0.80
No Evasive Action Taken	1.00

f. Formation:

Corrections found in Table 11 will be made to Basic Loss Table to account for formation of attacking aircraft.

TABLE 11 - FORMATION ("F")

Formation	"F" Factor
Tight	1.00
Loose	.85
Very Loose	.70

NOTE:

For definitions of formations, see note 1, 2, and 3 under Table 5).

g. Subsequent Runs ("R" Factor)

The Basic Loss Table is computed for the first run over the zone of fire after prior warning has been received. The correction is made in accordance with Table 12.

THIS PAGE IS DECLASSIFIED IAW EO 13526

TABLE 12 - SUBSEQUENT RUNS ("R" FACTOR)

Run	"R" Factor
First Run (No Warning)	0.00
First Run (Prior Warning)	1.00
Second Run	2.00
Third Run	3.00

h. Combined Losses:

Losses to flights which are engaged by both guns and automatic weapons (Alt. between 3000 and 6000 ft.) will be the sum of the losses incurred from each type of anti-aircraft fire.

i. Umpires will assume that all airdromes will be defended by one Battalion of anti-aircraft automatic weapons and by one Battalion of 90 MM Guns, except where the number is determined by the development of the tactical situation. In this case the Umpire will be given prior notification.

Losses of Aircraft Attacked by Night
or All-Weather Fighters.

1. Damage assessment of aircraft attacked by night or all-weather fighters will be made by the Umpire at the direction center which controls the intercepting aircraft. The aircraft will be judged destroyed when the radar screen at the control center shows a separation range of 1,000 feet or less.

THIS PAGE IS DECLASSIFIED IAW EO 13526

Appendix 6
To CAU Oper
Plan 1-50

REPORTING PROCEDURE

1. Air Umpire reports will be limited to essential facts pertaining to the mission and operations of the organization umpired.

2. Classification : All operations reports will be classified "Swarmer Secret".

a. Weekly Report: A weekly report will be submitted by the Chief Air Umpire to the Chief Umpire summarizing air umpiring activities. The initial report will be submitted on Friday following the initiation of reconnanissance operations on or about 15 April 1950. Subsequent reports will be submitted by the Chief Air Umpire on Friday of each week until 8 May 1950.

3. Air Umpire Summaries:

a. All Air Umpires will maintain a Chronological Summary of alll air activities pertaining to Operation Swarmer of the units they are umpiring,-ie, Force, Airdrome, TACC,-(and TADC when reportin direct to the Force, Air Umpire). Air umpires will include in their chronological summary a resume of all air activities observed by air umpires within their sphere of operation. This summary will be maintained for future reference in compiling the final report for the Chief Umpire. Summaries from lower echelons will be submitted to Airdrome Umpires at the Airdrome Umpier's direction.

4. Air Umpire Reports:

a. Strike Report: A strike report will be submitted by Airdrome Umpires to the Chief Air Umpire, with information copies to the Chief Umpire and the respective Force Air Umpire, immediately upon completion of each strike. See inclosure 1 (Completed Strike Mission Dispatch Report) and inclosure 2 (Hostile Strike Dispatch Report) for form of report.

b. Daily Operational Summary Report: A daily operational summary report will be submitted by each TACC (and TADC when reporting direct to the Force Air Umpire) Air Umpire to the Chief Air Umpire with information copies to the respective Force Air Umpire and the Chief Umpire as of 2400 EST daily, covering the past twenty-four hours. This report must reach the Chief Air Umpire by 1200 hours the following day. Reports are to begin 17 April 1950 and continue to the end of the exercise. Report will be consolidated from locally observed sources and the TADCs under the control of the TACC and/or the TADC. For form of report see (inclosure 3) TACC and/or TADC Operational Summary Report.

0298

5. Voice Radio Report:

a. Flying Umpire: In order to give the appropriate umpires as much information as possible it is necessary for the flying umpires to make certain reports over the Air Umpire Broadcast Net during each flight. Each airdrome of the Invasion and Defense Forces has been assigned a code letter and all strikes from each base will be numbered serially. Required reports are as follows:

(1) Within five (5) minutes after becoming airborne, the Flying Umpire will broadcast over the Air Umpire Broadcast Net, the base code letter and strike number, point and time of departure, number and type of aircraft, armament, and mission and/or specific targets, if known. This transmission need not be receipted for, and should not be repeated more than once even though no acknowledgement is received. Message form and sample message as follows:

(a) Code name or letter of objective, if known; if code name or letter of objective is unknown, use code letter "X-RAY".

(b) Flight Code letter and number.

(c) Number and type of remaining aircraft.

(d) Mission and/or specific target, if known (coordinates, if land target).

(f) Bearing and distance from target and altitude.

(g) Sample report: GEORGE BASE THIS IS FLIGHT ABLE FIVE ONE ZERO X EIGHT [illegible] X THREE ANGLES X FULL LOAD AMMO AND EIGHT ROCKETS PER AIRCRAFT X [illegible] ABLE ABLE POSITION AT FIVE FOUR ZERO SEVEN [illegible] X BEARING ZERO MILES X ANGLES FIVE X.

(2) In the event of an air attack in support of friendly ground troops, the report outlined in 5. a. (1) should be directed to the Umpire of the unit requesting the air strike, See example 5. a (1).

(3) Immediately after an attack, the Flying Umpire will call over the Air Umpire Broadcast Net and notify the surface or ground umpire whether or not a successful attack was made. Message form and Sample message as follows:

THIS PAGE IS DECLASSIFIED IAW EO 13526

(a) Call letter of unit attacked, if known: if unknown use code letter "X-RAY".

(b) Flight code letter and number.

(c) Attack completed.

(d) Effectiveness of attack.

(f) Sample report: CAPTAIN THIS IS FLIGHT BAKER FIVE ONE X ATTACK COMPLETED X SEVENTY FIVE PERCENT X.

6. Transmission of Reports: Unit, Squadron, Group and Wing Umpires will transmit strike reports and any daily operational summary reports required by the Airdrome, TACC and/or TADC Umpire to the next senior umpire in the umpire chain of control by personal contact, telephone or other available means. Airdrome, TACC (and TADC when reporting direct to the Force Air Umpire) Air Umpires will submit the daily operational summaries to Air Umpire Communication Center on that station for transmission to the Chief Air Umpire. (See Communications Annex for further clarification and methods of transmission of information)

7. Final Reports:

a. Airdrome Umpires will submit reports in the following form to their respective Force Air Umpires for consolidation, indorsement and submission to the Chief Air Umpire. Through the employment of a forwarding letter in which the assigned mission of the unit is outlined the Air Umpires above will submit information regarding the following:

Part I - Planning Phase

Part II - Training Phase

Part III- Operation Phase

Part IV - Redeployment Phase (this part to cover redeployment of Umpire elements only).

b. The completed report from each force umpire will be submitted to the Chief Air Umpire by 10 May 1950

AIRDROME OFFICERS SUMMARY REPORT

The Airdrome Officers Summary Report (MESSAGEFORM WD AGO Form 11-168) will be completed by answering the questions A thru L below and filling in the blanks opposite the same letters on the MESSAGEFORM with their answers:

a. List the Tactical Units on the station.

b. Numbers and type A/C possessed on the station by each unit.

c. Number and type of missions performed by each unit.

d. Number of A/C available for each mission by units.

e. Number and type of missions cancelled and reasons.

f. Personnel and Administration (pertaining to their effect upon the mission of each unit).

g. Intelligence items (pertaining to their effect upon the missions).

h. Operations items (pertaining to their effect upon the mission).

i. Maintenance and supply items (pertaining to their effect upon the missions).

j. Communications items (pertaining to their effect upon the missions).

k. List the subject and the date time groups of all messages dispatched to the Chief Air Umpire during the 24 hour period reported on.

l. Remarks: (List any pertinent items not covered in A thru L. When an item has previously been reported and there has been no change the words "NO CHANGE" will be entered in that space in lieu of repeating the same item).

AIR UMPIRE CHECK LIST

INSTRUCTION SHEET

1. To insure that the Air Umpire Group accomplished its mission as outlined, basic check lists have been prepared and are contained in this Appendix. Check Lists are provided for the following:

   a. Tactical Reconnaissance to include liaison type aircraft.

   b. Fighter (Jet).

   c. Troop Carrier.

   d. Light Bombardment.

   e. TACC

   f. TADC

2. In order to secure standardization and to achieve a means of evaluating the performance of participating tactical air units, the USAF, Operational Readiness Tests (ORT's) and the USN Administrative and Material Inspection Forms were used as a guide in preparing the Check Lists. Integrated into these tests and forms were the Training Objectives for each type organization.

3. In accomplishment of the Check Lists, it must be borne in mind that they were designed as a guide to assist in compilation of the final report on the exercise. Accordingly, it is not intended that they restrict or confine the scope of inquiry or observations of the umpire in his effort to determine fairly and accurately the status of a unit that he is observing. If additional items are observed, which are not included in the Check Lists, the items observed, together with manner of performance, may be included under REMARKS in the appropriate sections.

The evaluation of these additional items will be made by the Chief Air Umpire, and appropriate credit given to the particular unit.

4. The attached Check List enumerated in paragraph 1 above are each in two (2) parts. These are "Air Umpire Check List and Score Sheet" and "Air Umpire Final Score Sheet". The FORMAT used for the "Check List and Score Sheet" is similar to the form that is to be used in submitting Final Reports. This will obviously expedite compilation of the Final Reports. Based on job assignment, each umpire with tactical air units will accomplish both the appropriate "Air Umpire Check List and Score Sheet" and the "Air Umpire Final Score Sheet", or applicable portions thereof.

5. The "Air Umpire Check List and Score Sheet" is divided into three (3) main parts. (Part I: Planning Phase, Part II: Training Phase, Part III: Operations Phase). Each Part is sub-divided into five (5) Sections. (A: Personnel and Administration, B: Intelligence, C: Operations, D: Logistics, and E: Communications). Each Section contains one or more items to be checked. Each item has a scoring box beside it on the right hand margin. One half of the scoring box contains a number. This number represents the maximum amount that the umpire may give for that particular item.

6. The umpire will fill in the right hand half of the scoring box <u>ONLY</u> for those items personally checked, evaluated or observed. The remaining item score boxes will remain unscored.

7. When Umpire has completed scoring all possible items (right hand half of scoring box), he will then add up the maximum scores of only those items observed and place that total maximum score in the "MAX" side of the score box opposite each section heading. Then he will add up the unit's score (Umpire's rating) and place that total score in the Unit side of the score box opposite each section heading. This process is repeated for each of the five Sections in each of the three "Parts".

THIS PAGE IS DECLASSIFIED IAW EO 13526

8. The five Section Maximum scores are then added.

9. Next, total the five (5) section Unit scores and place the total score in the "Unit" side of the Score Box opposite "Total Score for Part I, II, or III as the case may be.

10. Now you are ready to fill in the "Air Umpire Final Score Sheet". In "Summary of Umpires Score" section, take each section separately and add the total score (Max and Unit) for each of the three parts. These total scores are to be placed opposite appropriate Items rated under proper heading (Max Score or Unit Score).

EXAMPLE:

II Part I - Planning Phase

	MAX	UNIT
Section B: Intelligence	15	12
Part II - Training Phase		
Section B: Intelligence	10	5
Part III - Operation Phase		
Section B: Intelligence	20	8
Final Score for Section B Intelligence	45	25

Opposite "Intelligence" under "MAX" Score, place 45

Opposite "Intelligence" under "UNIT" Score, place 25

12. Repeat this procedure for each of the other four (4) sections, add each score separately (Max and Unit), and divide total Max Score by total Unit Score. The result will be the "FINAL SCORE" in percentage.

13. <u>SUBMISSION</u>: Each Tactical Air Umpire will submit one copy of his completed Check Lists and Final Score Sheet to the next higher Air Umpire echelon. The Score Sheets will be consolidated and in turn be forwarded. On arrival at each echelon of command the Check Lists will be utilized in

THIS PAGE IS DECLASSIFIED IAW EO 13526

preparing the required Final Reports. Individual Squadron/Group Umpire Check List(s) will be attached to the various Final Reports as inclosures when forwarded. The form will be SWARMER SECRET when filled out. The originator will be responsible for having the complete form stamped SWARMER SECRET.

14. SUMMARY:

a. THE IMPORTANCE OF THE SUMMARY CONNOT BE OVER-EMPHASIZED. PROMULGATED HEREIN IS THE CRUX OF THE ENTIRE MANEUVER. HERE IS THE ONE OPPORTUNITY FOR THE AIR UMPIRE TO DEVIATE FROM THE STEROTYPE NUMERICAL RATING SYSTEM AND EXPRESS HIS INDIVIDUAL OPINIONS CLEARLY AND CONCISELY.

b. THE SUMMARY WILL BE THE FOCAL POINT OF ATTENTION FOR ALL REVIEWING AGENCIES. THE EFFICIENCY OF THE UMPIRE, AS WELL AS THE SUCCESS OF THE JOINT MANEUVER, IS REFLECTED BY HOW CAREFULLY AND CONCISELY THE SUMMARY IS PREPARED.

c. EACH PHASE MUST BE SUMMARIZED UPON COMPLETION OF THAT PARTICULAR PHASE. FOR THE PURPOSE OF REPORTING STANDARDIZATION, THE PHASE SUMMARY WILL INCLUDE:

(1) DISCUSSION OF UNUSUAL DIFFICULTIES OR ACCOMPLISHMENTS.

(2) UMPIRE COMMENTS.

(3) UMPIRE RECOMMENDATION(S)

AIR UMPIRE CHECK LIST AND SCORE SHEET

TROOP-CARRIER

Date____________

PART I - Planning Phase

Section A: Personnel and Administration — MAX | UNIT

SCORE: MAX | UNIT

		MAX	UNIT
(1)	Administration and Records: Is the unit capable of efficient administration and maintenance of records, operating either as an independent squadron or as a part of a task force, wing or group?	10	
(2)	Medical: Evaluate apparent status of health of personnel of the Unit with respect to accomplishment of its mission.	5	
(3)	Does Unit plan include Chaplains' services?	5	
(4)	Mess: Quality, operation and supervision. Ability to operate in the field.	5	

REMARKS:

Section B: Intelligence — MAX | UNIT

		MAX	UNIT
(1)	Are Intelligence personnel fully utilized in mission planning?	5	
(2)	Are there adequate facilities for operational briefings?	5	
(3)	Are briefing personnel familiar with subjects such as: (a) Identification of drop zone (b) Importance of target (c) Alternate target (d) Enemy capabilities (e) Reporting procedures	10	

0345

THIS PAGE IS DECLASSIFIED IAW EO 13526

TROOP CARRIER

Air Umpire Check List and Score Sheet Cont'd

REMARKS:

Section C: Operations

MAX	UNIT

(1) Is operations section prepared to sustain unit effective flying? (Ability of unit to schedule 75% of assigned aircraft operational during the maneuvers?) — 25

(2) Does operations have a plan and a standing operating procedure which adequately covers the unit phase of maneuvers? — 15

(3) Was the DZ selected jointly with the commander of the Airborne Unit? — 5

(4) Was there a mutual exchange of liaison personnel between troop carrier and Airborne Units? — 5

(5) Was pertinent photo coverage requested? (DZ, LZ, Routes) — 5

(6) Was a joint Command Post established at the departure base? — 5

(7) Were joint-planning conferences held? — 5

REMARKS:

Section D: Logistics

MAX	UNIT

(1) Has movement and staging preparations for proposed move to combat area been thoroughly planned? — 25

(2) Do plans provide for aerial re-supply of ground units? If so, have the plans been coordinated with other sections? — 5

0346

TROOP CARRIER

Air Umpire Check List and Score Sheet Cont'd

(3) Evaluate completeness of logistical plan for support of unit mission(s) — 10

REMARKS:

Section E: Communications — MAX | UNIT

(1) Evaluate completeness of communications plan for execution of unit mission. — 30

(2) Has the communications plan been properly coordinated with other units? — 10

REMARKS:

TOTAL SCORE FOR PART I PLANNING PHASE

PART II - Training Phase

Section A: Personnel and Administration — MAX | UNIT

(1) Personnel: Observe officers and airmen, both on and off-duty, for general military appearance, courtesy and conduct. — 15

(2) Training Status: Are all personnel adequately trained in primary duty? (Assignment) — 10

(3) Records: Are training records adequate and up-to-date? (Appropriate level) — 5

0347

TROOP CARRIER

Annex "B"
CAU Oper
Plan 1-50

AIR UMPIRE SECTION (SWARMER)
Ft Bragg, North Carolina

COMMUNICATIONS

1. MISSION

It is the purpose of this plan to:

(a) Provide communications facilities for the immediate transmission of Air Umpire control orders and information as required during every phase of Exercise Swarmer.

(b) Indicate correct routing procedures for Air Umpire traffic.

(c) Outline methods to be utilized in providing unit reports on maneuver activities to the Chief Air Umpire for final evaluation.

2. COMMUNICATIONS FACILITIES

a. Wire will be the primary means of point to point communications for Air Umpire traffic. Circuits will be provided for control orders and umpire information as follows:

(1) Between each Air Base and its Force Headquarters

(2) Between each Force Headquarters and the Chief Air Umpire

(3) Between the Chief Air Umpire and other sections within the Chief Umpire Headquarters.

(4) Between the Liaison Officers of the two Force Headquarters

(5) Between the Air Umpire, U.S. Force Headquarters, and the Tactical Air Force

(6) Between the Air Umpire, U.S. Force Headquarters, and the Tactical Air Control Center

(7) Between the Tactical Air Control Center and each Tactical Air Direction Center

(8) Three (3) circuits between the Chief Air Umpire and the Air Task Force

(9) Between the Chief Air Umpires and the Ground Task Force.

0385

THIS PAGE IS DECLASSIFIED IAW EO 13526

(10) Necessary switching points will be established at Force Headquarters and JOC-JACC to permit the completion of circuits between Air Umpires and Ground Umpires

(11) Presently existing permanent wire circuits will be utilized between Air Base Umpires and Unit Umpires located on the same installation.

b. The VHF Air-Ground Net will be used by Flying Air Umpires to pass information concerning the Umpire Air Action to other interested umpires, and the transmission of orders. A VHF channel as designated by COI, Maneuver Headquarters, will be used only by Air Umpires. Care must be exercised at all times by Air Umpires flying with Troop Carrier aircraft to preclude excessive use of the aircraft command radio for umpire purposes. Such use of these radios will be made secondary to tactical use. Air Umpires will at all times ascertain that tactical transmission or reception is not contemplated by aircraft crews prior to use of the command radio. The VHF Air-Ground Net will be composed of stations as follows:

(1) Flying Air Umpires

(2) Chief Air Umpires (Mackall Air Base)

(3) Air Umpire, U.S. Force (Mackall Air Base)

(4) Air Umpire, Defense Force (Pope Air Force Base)

(5) Airdrome Umpire (Langley Air Force Base)

(6) Airdrome Umpire (Shaw Air Force Base)

(7) Airdrome Umpire (Congaree Air Base)

(8) Airdrome Umpire (Laxton Air Base)

(9) Airdrome Umpire (Oceana Naval Air Station)

(10) Air Umpire Tactical Air Control Center (Mackall Air Force Base)

(11) Air Umpire Tactical Air Direction Center

(12) Air Umpire Tactical Air Direction Center

(13) Air Umpire Tactical Air Direction Center (Defense)

(14) Ground Umpire (Anti-Aircraft)

(15) Ground Umpire (Anti-Aircraft)

c. HF Radio will be used as the primary means of communications between the Air Umpire, U.S. Force, and the Air Umpire moving between units being resupplied by air within the maneuver area. Further, this channel will serve as a secondary or back-up circuit for those circuit outlined in paragraph 2 a above in the event of saturation and/or failure of wire circuits. HF radio stations will be established as follows:

(1) Chief Air Umpire - - NCS (Mackall Air Base)

(2) Air Umpire, Defense Force (Pope Air Force Base)

(3) Airdrome Umpire (Langley Air Force Base)

(4) Airdrome Umpire (Shaw Air Force Base)

(5) Airdrome Umpire (Maxton Air Base)

(6) Airdrome Umpire (Congaree Air Base)

(7) Airdrome Umpire (Oceana Naval Air Station)

(8) Air Umpire - - Mobile (Fort Bragg Maneuver Area)

d. All radio facilities provided for Air Umpire activities on Mackall Air Base will be installed, and maintained by personnel of the Umpire Group. Those facilities provided other Air Umpire will be installed, operated, and maintained as follows:

(1) On SCR 399 Radio Set will be provided each Air Umpire listed in paragraph 2c above to be installed, operated, and maintained by personnel assigned by the Chief Air Umpire for this purpose.

(2) One SCR 624 Radio Set will be provided each Umpire listed in paragraph 2b above. In the case of those Air Umpires also provided with HF radio facilities, personnel assigned for the installation, operation, and maintenance of SCR 399 Radio Sets will similarly install and maintain VHF ground stations. Those VHF ground stations provided Air Umpires of Tactical Air Control organizations will be installed and operated by personnel of the organization.

3. ROUTING PROCEDURES

a. Channels available for the routing of traffic within the Air Umpire communications net are as indicated on inclusures 1,2,3.

b. Airdrome Umpires will transmit reports to Force Umpires in the manner and priority as listed below:

(1) Wire telephone

0387

(2) Radio Telephone

(3) Radio Telegraph

(4) Teletype (Command and administrative channels)

(5) VHF radio relay

c. TACC Umpires will make reports to Force Umpires in the same manner as paragraph 3b above.

d. Flying Umpires can make flash reports to any activity included as a part of the VHF airground net as listed on inclosure 2. Reports to be forwarded to the Chief Air Umpire will be transmitted to the station within the nearest proximity to Mackall Air Base, with a request to relay the message to the Chief Air Umpire by wire circuits.

e. Force Umpires will transmit necessary reports to the Chief Air Umpire by telephone.

f. All reports telephoned to an Air Umpire at Umpire Headquarters Mackall Air Base, will be called in to "Air Umpire Report" through the switchboard at Mackall Air Base.

g. A central reporting center will be established by the Chief Air Umpire to receive, transcribe, and deliver all reports received by telephone and radio.

h. The Chief Air Umpire will have available those channels listed in paragraph 3b above for the transmission of control and administrative traffic to subordinate air umpires. In addition, circuits will be available to the Tactical Air Force switchboard insuring access to direct operational circuits to each participating air base for control of tactical organizations.

COMMUNICATIONS OPERATING INSTRUCTIONS

a. GENERAL:

1. This COI will be effective between the dates 1 April - 10 May inclusive.

2. Signal communications within the Air Umpire Group will conform with the instructions listed herein.

3. Any signal matter not covered by these instructions will be reported to the Communications Officer, Air Umpire Group.

4. In the event of communications equipment failure, the Communications Officer, Air Umpire Group, will be notified so that necessary arrangements can be made to effect immediate repairs.

b. AIR UMPIRE COMMUNICATIONS SYSTEMS:

1. Telephone will be the primary means of ground point-to-point communications between Air Umpires.

2. HF Radio will be provided as an overload net.

3. VHF Radio will be used for Air - Ground umpire traffic.

4. Teletype circuits are provided between Maneuver Headquarters at Mackall Air Base and all Air Bases for command and administrative purposes. These teletype circuits may be used by Air Umpires in case of emergency when Air Umpire circuits are not available.

c. TELEPHONE:

1. Wire nets are as indicated on Inclosure 1, Annex B Operations plan 1-50.

2. All telephonic Air Umpire reports at Mackall Air Base will be received by a central reports section, processed, and delivered to the addressee by messenger.

3. Base telephone systems will be used by unit umpires in reporting to Base Umpires.

d. RADIO:

1. HF Radio Nets as indicated on Inclosure 3, Operations Plan 1-50

THIS PAGE IS DECLASSIFIED IAW EO 13526

2. VHF Radio Nets are as indicated on Appendix 2, Operations Plan 1-50

3. Radio Frequencies and Call Signs are as listed in Appendix 3, Operations Plan 1-50

4. Air Umpire facilities will not use any frequency or call signs listed on Appendix 3, Operations Plan 1-50 without prior approval of the Chief Air Umpire.

5. The highest headquarters operating in the net will act as Net Control Station unless otherwise indicated.

6. All HF Radio stations will be operated from 0800 - 2000 daily unless otherwise directed.

c. RADIO TELEPHONE PROCEDURE:

1. All messages will be clear and concise.

2. Messages will be spoken slowly, in natural phrases, with each word enunciated. Since messages will be copied, time must be allowed for the receiving operator to copy in printed form.

3. All stations will maintain a copy of messages sent and received, including the name of sender and receiver, with the date and time of the originator.

4. When necessary to identify any letter or numeral, the following standard phonetics will be used:

A - ABLE	J - JIG	S - SUGAR
B - BAKER	K - KING	T - TARE
C - CHARLIE	L - LOVE	U - UNCLE
D - DOG	M - MIKE	V - VICTOR
E - EASY	N - NAN	W - WILLIAM
F - FOX	O - OBOE	X - XRAY
G - GEORGE	P - PETER	Y - YOKE
H - HOW	Q - QUEEN	Z - ZEBRA
I - ITEM	R - ROGER	

0393

1 - WUN	6 - SIX
2 - TOO	7 - SEV - VEN
3 - THUH - REE	8 - ATE
4 - FO - WER	9 - NINER
5 - FI - YIV	0 - ZERO

5. Difficult words will be spelled phonetically and the word will be spoken before and after the spelling, EXAMPLE, "MAXTON - I SPELL, MIKE, ABLE, XRAY, TARE, OBOE, NAN - MAXTON"

6. Numbers will be spoken digit by digit except that exact multiples of hundreds and thousands may be spoken as such. EXAMPLE

39	THUH - REE NINER
14	WUN FO - WER
400	FO - WER HUN - DRED
7568	SEV - VEN FI - YIV SIX - ATE
7000	SEV - VEN THOW - ZAND

7. Dates and time groups will always be spoken by digits.

8. All plain language messages transmitted by radio or wire making reference to simulated enemy or combat forces, such as in combat or amplifying reports will be identified by the use of the word "Umpire" at the beginning and end of the text. This procedure for identifying such traffic is used in order not to alarm units or persons not engaged in Exercise Swarmer.

ELECTRONICS COUNTERMEASURES:

1. No countermeasures will be used against Air Umpire Communications.

2. Any report of jamming of air aids to navigation, Umpire Communications Circuits, or commercial circuits will immediately be reported to the Chief Air Umpire, stating time, frequency, type of jamming, and direction if known.

0394

SECURITY:

1. Traffic to be routed over Air Umpire Channels will not be enciphered. Traffic of such a nature to warrant enciphering will be enciphered and transmitted by the use of organizational command and administrative facilities.

2. No radio circuit in the Air Umpire net will be authorized as an approved circuit for the transmission of classified information.

3. Careless or excessive use of radio telephone is a serious hazard to transmission security. Since such equipment can be operated by other than trained communication personnel, strict control must be exercised to maintain correct procedure, circuit discipline, and adherence to security precautions.

4. The following malpractices will be avoided:

   a. Misuse and confusion of Call Signs. This may result in the non-delivery of an important message.

   b. Unofficial conversations between operators.

   c. Transmitting in a directed net without permission of the NCS.

   d. Unnecessary transmissions including unnecessary test periods.

   e. Incorrect and unauthorized procedure.

   f. Excessively long calls.

   g. Failure to guard operating frequencies.

5. No authentication will be used on Umpire Channels.

6. Umpire circuits will not be required to observe silence.

7. The Chief Air Umpire will monitor all tactical frequencies utilized during Exercise Swarmer.

TIME: The time zone suffix QUEEN (Q) will be used for all traffic transmitted on Air Umpire Channels.

THIS PAGE IS DECLASSIFIED IAW EO 13526

Appendix 2
Annex "B"
CAU Oper
Plan 1-50

COMMUNICATIONS CHECK LIST

1. Unit Air Umpires will be provided check lists to provide the necessary guides in furnishing the Chief Air Umpire a comprehensive evaluation of communications and electronics activities as employed during Exercise Swarmer.

2. Check Lists A and B will be used by all unit umpires reporting on units employing communications.

3. Check List C will be used only by Air Umpires reporting on radar activities. Those officers will also be guided by so much of Check Lists A and B as pertains to the type of organization being umpired.

4. Normally all items included on check lists will be used as guides with the final report including only those items that were outstanding or deficient in nature.

5. It is to be borne in mind that reports are intended to give an accurate reflection of the operational effectiveness of the unit being umpired.

CHECK LIST A

Planning and Training Phase

1. Is the communications plan of the next higher headquarters adequate to make provisions for all requirements of the unit being umpired ?
2. Is the Unit Communications Plan adequate to support the mission ?
3. Does the plan provide for an alternate method of communications ?
4. Are all personnel familiar with established SOP or CCI ?
5. Are adequate publications on hand ?
6. Is there any shortage of authorized communications personnel ?
7. Does the T O & E provide sufficient personnel in the necessary classifications ?
8. Is communications briefing of air crews adequate ?
9. Is there a shortage of major items of equipment or supply ? If so, why ?
10. Does the T O & E provide sufficient equipment to perform the mission ?

CHECK LIST B

Operational Phase

1. Were any changes made in the Communications Plan ? Why ?
2. Were any communications problems encountered that were not anticipated ?
3. Were communications facilities adequate ?
4. What communications failures were observed ?
5. To what can these failures be attributed ?
6. Was there any radio interference ? If so, of what nature ?
7. Were adequate physical security measures employed to safeguard classified information ?
8. Was classified communications traffic prepared in accordance with security standards ?
9. Were there any reported violations of cryptographic security ?
10. To what extent can communications be improved ?

THIS PAGE IS DECLASSIFIED IAW EO 13526

CHECK LIST C

Radar

1. Were radar installations sited such that the maximum capability of the equipment could be exploited?
2. Were interceptions accurately and quickly made?
3. Was jamming encountered?
4. How was jamming or other electrical interference combatted?
5. Was plotting rapid, accurate, and effective?
6. At what range were pips detected on early warning sets?
7. Did operating personnel exhibit adequate qualifications in duty specialties?
8. Was the equipment adequate to perform the mission?

Annex "C"
CAU Oper
Plan 1-50

AIR UMPIRE SECTION (SWARMER)
Ft Bargg, North Carolina

L O G I S T I C S   I N S T R U C T I O N S

1. The purpose of this annex is to furnish information relative to logistic support for Air Umpires, and guidance in determining and locating data concerning the causes of logistic effect on air operations.

2. Umpires:

a. The 95th Military Government Group, Ft. Bragg, is charged with the responsibility of furnishing billets, mess, transportation, office and school equipment, supplies and Umpires kits for Air Umpires assigned to Ft. Bragg and Camp Mackall. Student Air Umpires will be afforded same facilities as cited above during stay at Ft. Bragg.

b. Umpire personnel assigned to field areas shall be furnished billets, mess transportation, supplies and equipment from organization to which assigned.

3. Concept of data concerning Air Umpire Check-Off list and Score sheet:

a. Supply and Maintenance. In determining the effect of maintenance and supply on the overall mission, it behooves each umpire to secure information from the activity responsible for the performance of that part of the mission affected.

(1) Information leading to logistical plans for tactical and supporting units, and to the availability and condition of required supplies and equipment will be in possession of the Wing Materiel Officer or Organization Commanders.

(2) Information as to adequacy and/or inadequacy of supply and equipment to support organizations can best be obtained from the appropriate accountable officer.

(3) Air Forces and Signal supplies and equipment to support radar, fixed, and mobile communications equipment will be located at each net installation.

(4) To determine technical qualifications of materiel personnel, it is necessary to observe and note their performance of maintenance and supply functions with reference to percentage of aircraft in commission, combat readiness, and mission aborts (Special attention will be given AOCP percentages and its contributing causes.)

(5) Tactical unit facilities are those facilities affording efficient maintenance and arming of aircraft, hangars, maint docks, stands, engine change mounts, jacks, etc., and transportation for loading and ready delivery of supplies and equipment.

(6) Efficient refueling is dependent on proper spotting and spacing of aircraft as well as quantity and quality of the servicing units and operations.

b. Transportation. Comments and recommendations are invited on the adequacy of air and vehicular transportation in relation to its effectiveness in supporting the overall mission.

Annex D
CAU Oper
Plan 1-50

AIR UMPIRE SECTION (SWARMER)
Ft Bragg, Nort Carolina

ADMINISTRATIVE INSTRUCTIONS

ANNEX "D"

1. Strength, Records, and Reports.

a. Morning Reports.

(1) All air umpires and airmen assigned to the Umpire Group will be carried on the morning report of the 95th Mil Govt Det, Exercise Swarmer (Prov), while on duty at Fort Bragg and Camp Mackall.

(2) Air umpires and airmen placed on further TDY with units participating in the maneuver, and who are ordered to return to the Umpire Group at Fort Bragg upon completion of the exercise, will continue to be carried on the morning report of the 95th Mil Govt Det, Exercis Swarmer (Prov), for administrative purposes, and will be picked up on the morning report of the unit to which assigned for quarters and rations only.

(3) Air umpires placed on further TDY to units participating in the maneuver, and who will be directed to report directly to their home station upon completion of the exercis, will be dropped from the morning report of the 95th Mil Govt Det, Exercise Swarmer (Prov) and picked up by the unit to which assigned as umpire.

b. Strength Accountability.

(1) The 95th Mil Gov Det, Exercise Swarmer (Prov), will submit a daily strength report to the Chief Air Umpire indicating the status of all Air Force Personnel assigned to the umpire Group.

(2) Changes in status of air umpires and airmen on duty with units participating in the maneuver will be reported to the Chief Air Umpire by Airdrome umpires.

c. Personnel Records.

(1) Personnel records of airmen will be maintained by the 95th Mil Govt Det, Exercise Swarmer (Prov).

(2) Personnel records of Air Force and Naval Officers will be maintained by the J-1 of Maneuver Headquarters.

d. Effectiveness Reports. Effectiveness Reports will be submitted by the Chief Air Umpire on all officers under his jurisdiction when required by current Air Force directives. Effectiveness Reports are not required for those Air Force officers whose period of TDY is less than sixty (60) days.

e. Disposition of Records. All records on file in the office of the Chief Air Umpire upon completion of the maneuver will be disposed of as directed by the Maneuver Commander.

2. Replacements.

a. Casualties and AWOLs. Air Umpires or airmen casualties or AWOLs serving with units participating in the exercise normally will be replaced by personnel assigned to the office of the Chief Air Umpire.

b. Disposition Upon Return to Duty. Air umpires or airmen returning from hospital or sick-in-quarters to a duty status will report to their immediate superior umpire for instructions. Such personnel normally will be instructed to continue their umpire duties in the exercise.

3. Discipline, Law, and Order.

a. Courts-Martial Jurisdiction. The Commanding General, Fourteenth Air Force, exercises General Courts-Martial jurisdiction over all Air Force personnel assigned to the Umpire Group.

b. Conduct and Dress. All Air Force officers and airmen assigned to duty with the Umpire Group will maintain their dress and appearance, and will conduct themselves in such a manner as to reflect credit upon the United States Air Force.

c. Chain of Command. The normal chain of command for air umpires serving with units participating in the exercise will be from squadron umpire to group umpire, to wing umpire, to airdrome umpire, to Force Umpire, to the Chief Air Umpire.

4. Fatalities.

a. Reports. Air umpire fatalities will be processed through normal channels as required by current directives.

b. Disposition of Effects. Effects of deceased air umpires will be disposed of as provided by current directives.

5. Morale.

a. Postal.

(1) Personnel on duty with the office of the Chief Air Umpire at Fort Bragg or Camp Mackall will have their mail addressed

0403

with name, grade, service number, and the word "Umpire", followed by "Exercise Swarmer", Fort Bragg, North Carolina.

EXAMPLE: Captain John S. Smith 123456 A
Umpire - Exercise Swarmer
Fort Bragg, North Carolina

(2) Air umpires or airmen serving with units participating in the maneuver will have mail addressed with name, grade, service number, followed by the unit to which attached, and the maneuver base from which the unit is operating.

EXAMPLE: Captain John S. Smith 23456 A
21st Fighter Squadron
Pope AFB, Fort Bragg, North Carolina

b. Finance.

(1) Airmen will be paid on the regular payroll of the 95th Mil Govt Det, Exercise Swarmer (Prov) while at Smoke Bomb Hill, Fort Bragg, and at Camp Mackall. Airmen who are attached to tactical units participating in the exercise will be paid a partial payment prior to their departure, provided the date of departure is such as to justify such payment.

(2) All officers will be responsible for making suitable arrangements with the Post Finance Officer at Fort Bragg, their home station, or, if applicable, the organization which they umpire, regarding their own pay matters.

(3) The 95th Mil Govt Det, Exercise Swarmer (Prov), will prepare travel allowance vouchers for officers and airmen on duty at Fort Bragg, or Camp Mackall.

c. Religious Services.

(1) Religious services for personnel on duty at Fort Bragg will be provided by the Commanding General, Fort Bragg.

(2) Religious services for personnel on duty at Camp Mackall will be provided by the Commanding General, V Corps.

(3) Religious services for personnel serving on duty with tactical units participating in the exercise will be provided by the unit to which they are attached.

d. Decorations and Awards. Current directives regarding recommendations for awards or decorations will apply.

THIS PAGE IS DECLASSIFIED IAW EO 13526

e. Leaves and Passes:

(1) Passes for air umpires and airmen will not be granted during the actual maneuver period.

(2) Leaves will be authorized only in the case of a bona fide emergency verified by the Red Cross. Such leaves must be approved by the Chief Air Umpire.

6. Administrative Methods:

a. Personnel Requirements:

(1) The Chief Air Umpire will determine the personnel requirements for his staff and for air umpires necessary to umpire the maneuver.

(2) Requisitions for personnel will be submitted to the Maneuver Commander through the Chief Umpire.

b. Assignment of Air Umpires:

(1) The Chief Air Umpire will determine the unit of assignment of all air umpires.

(2) Orders pertaining to the assignment of air umpires and airmen will be issued by the Maneuver Commander upon request from the Chief Air Umpire.

c. Mess:

(1) Messing facilities for officers and airmen serving with tactical units participating in the exercise will be furnished by the unit to which they are assigned.

(2) Messing facilities for officers and airmen on duty with the Chief Air Umpire at Fort Bragg will be furnished by the 95th Mil Govt Group.

(3) Messing facilities for officers and airmen on duty at Camp Mackall will be furnished by the Commanding General, V Corps.

(4) Officers eating in troop messes will pay cash for each meal.

(5) Enlisted men will not be authorized to ration separately.

0405

THIS PAGE IS DECLASSIFIED IAW EO 13526

d. Quarters:

(1) The 95th Mil Govt Group will provide quarters for all officers and airmen while at Fort Bragg.

(2) Quarters for officers and airmen on duty at Camp Mackall will be provided by the Commanding General, V Corps.

(3) Quarters for officers and airmen serving with tactical units participating in the exercise will be provided by the unit to which attached.

7. Medical:

a. Fort Bragg. The 95th Mil Govt Det, Exercise Swarmer (Prov), will maintain the sick report for all personnel at Fort Bragg. Personnel reporting on sick call will use the facilities of the dispensary in the 4th Signal Bn Area.

b. Camp Mackall. The Commanding General, V Corps, will provide medical facilities for personnel at Camp Mackall.

c. Tactical Units. Medical facilities for air umpires and airmen serving with tactical units participating in the exercise will be provided by the unit to which attached.

8. Miscellaneous:

a. Flying:

(1) Air Force Officers on flying status who are serving as members of the Chief Air Umpires staff will be attached to Pope Air Force Base for flying.

(2) Inadequacy of flying facilities precludes the possibility of furnishing an opportunity to officers attending the Air Umpire School to maintain their flying proficiency.

(3) Air Force Officers on flying status who are serving with tactical units participating in the exercise will be attached to the unit with which serving for flying.

THIS PAGE IS DECLASSIFIED IAW EO 13526

b. Forms 5: Air umpires on flying status, who report to the Umpire Group for the purpose of attending the Air Umpire School, will retain their Forms 5 in their possession until they report to the tactical unit which they are to umpire, at which time they will turn their Forms 5 over to the Operations Officer of the unit.

AIR UMPIRE SECTION (SWARMER)
Fort Bragg, North Carolina

ANNEX "E"
CAU OPER
PLAN 1-50

23 February 1950

ANNEX E

Definitions

Airborne - A Term: 1. Applied to personnel, equipment, etc., organically transported by air, such as Airborne Infantry.

2. Used to indicate gear and other equipment not an integral part of the plans, such as Airborne Radar, etc.

3. Applied to an aircraft from the instant it becomes entirely sustained by air until it ceases to be so sustained. A Lighter-Than-Air aircraft is not considered to be airborne when it is attached to the ground, except that moored balloons are airborne whenever sent aloft.

Air Defense - All measures designed to nullify or reduce the effectiveness of the attack of hostile aircraft or guided missiles after they are airborne.

Air Space Reservation - The air space located above an area on the surface of the land or water, designated and set apart by executive order of the President or by a State, Commonwealth, or Territory, over which the flight of aircraft is prohibited or restricted for the purpose of National Defense or for other Governmental purposes.

Air Superiority - That degree of capability (Preponderance in morale and material) of one air force over another which permits the conduct of air operations by the former at a given time and place without prohibitive interference by the opposing Air Force.

Air Support - An air operation designed to create an effect which will assist in the accomplishment of the task assigned the Force as a whole.

Artillery Adjustment - Is the placing of Artillery Fire upon known or suspected enemy installations and/or upon a known point, which may be used as a reference point for shifting fires, using observed or unobserved means after applying Registration corrections to the firing data.

Counter-Intelligence - Is that aspect of intelligence relating to all security control measures, both active and passive, designed to insure the safeguarding of information, personnel, equipment, and installations against the espionage, sabotage, or subversive activities of foreign powers and of disaffected or dissident groups or individuals which constitute a threat to the National Security.

Counter-Measures - That form of Military Science which by the employment of devices and/or techniques, has as its objective the impairment of the operational effectiveness of enemy activity.

0408

THIS PAGE IS DECLASSIFIED IAW EO 13526

D-Day - The term used to designate the unnamed day on which an initial assault landing or phase of operations is to commence.

Dissemination - The distribution of intelligence and information in such a manner as to insure that it reaches the agencies needing it, in usable form, and in accordance with this urgency.

Echelon - 1. The subdivisions of a headquarters, as forward echelon, rear echelon.

2. Separate levels of Command; as compared to regiment, division is a higher echelon, and battalion is lower echelon.

3. The different fractions of a command in the direction of depth, to each of which a principal combat mission is assigned.

Embarkation - The loading of troops with their supplies and equipment into aircraft.

Escort - 1. To convoy.

2. A combat unit or units assigned to accompany and protect a weaker force.

3. Airplanes assigned to protect other aircraft during a mission.

4. An armed guard that accompanies a convoy, a train, prisoners, etc.

Espionage - The use of secret agents to obtain information concerning a possible or actual enemy or theater of operations, including terrain and weather.

Evacuation - 1. The process of moving casualties from a battle field and subsequently of moving them along the chain of evacuation as necessary.

2. The clearance of personnel, animals, or materiel from a given locality.

Evaluation - The determination of the pertinence, credibility, reliability and accuracy of an item of information.

Fields, Emergency - Landing fields that may be utilized by aircraft which have encountered unforeseen difficulties in flight.

Flight - 1. In Naval and Marine usage a specified group of aircraft usually engaged in a common mission.

2. The basic Tactical Unit in the Air Force, consisting of two or more aircraft.

Force (s) - A body of troops, or aircraft, or combination thereof.

Formation - The arrangement of the elements of a command in any prescribed manner.

THIS PAGE IS DECLASSIFIED IAW EO 13526

IFF (Identification Friend or Foe) - A system of radio interrogation and reply (if friend). Generally used in connection with radar for identifying an aircraft, ship, or craft.

Intelligence - The product resulting from the collecting, processing and evaluation of information concerning actual and potential situations, conditions and capabilities relating to foreign activities, and to foreign or enemy-held areas.

Interception - 1. The process of flying friendly aircraft to meet a force of hostile aircraft and of engaging the enemy force to hinder or prevent it from carrying out its mission.

2. The process of gaining possession of communications intended for others by copying, recording, or by any other means.

Interdiction - To prevent or hinder, by any means, enemy use of an area or route.

Jamming, Radar - The deliberate radiation of electromagnetic waves to prevent radar from being effective.

Liaison - That contact or intercommunication maintained between parts of an Armed Force to insure mutual understanding and unity of purpose and action. It is often aided by exchange of Officers and/or men in order to keep up an exchange of information.

Logistics - That part of the entire Military activity which deals with production, procurement, storage, transportation, distribution, maintenance and evacuation of personnel, supplies and equipment; with induction, classification assignment, welfare and separation of personnel; and with facilities required for the support of the Military establishment, including construction on and operation thereof. It comprises both planning and implementation.

Organic - Assigned to, and forming an essential part of, a Military Organization. Organic parts of a unit are those listed in its tables of organization for the Army, Air Force, and Marine Corps, and are those assigned to the administrative organization of the operating forces for the Navy.

Organic Air Umpire - An Air Umpire assigned to, and forming an essential part of, the Military Organization upon which he rates and renders umpire reports for an exercise. He is appointed by, and functions as directed by, a member of the Air Umpire Group.

Pathfinders - 1. (Aircraft) Experienced airplane crews who lead a formation to the drop zone, release point, or target.

2. (Airborne) Teams dropped at an objective to establish signal devices for aircraft homing in preparation for an airborne mission.

Psychological Warfare - The employment of any non-lethal means designed to affect the morale and behavior of any group for a specific Military purpose.

Reconnaissance - The directed effort in the field to gather information of the enemy, terrain or resources which is undertaken by an appropriate element of the Armed Forces. Not to be confused with espionage.

Search & Rescue - The use of aircraft, surface craft, submarines, and other special equipment employed for the rescue of personnel in distress on land or at sea.

Security - Measures taken by a command to protect itself from espionage, observation, sabotage, annoyance, or surprise.

Security, Communications - The protection resulting from all measures designed to deny to unauthorized persons information of value which might be derived from communications.

Sortie - One aircraft airborne on a mission against the enemy. Four aircraft would be 4 Sorties, etc.

Strategic Air Warfare - Air combat and supporting operations designed to effect, through the systematic application of force to a selected series of vital targets, the progressive destruction and disintegration of the enemy's war-making capacity to a point at which he no longer retains the ability or the will to wage war.

Strike - Aconcerted air attack on a single objective.

Supply, Air - The delivery by Air of items to drop or landing area.

Support, Close Air - The attack by aircraft of hostile ground targets which are so close to friendly forces as to require detailed integration on each Air Mission with the fire and movement of these forces.

Support, Deep Air - Those supporting air operations that take place in the objective area, but at such range from friendly ground forces as to require no direct coordination between aircraft and front line units other than the establishment of a bomb line, beyond which offensive air operations are unrestricted.

Tactical Air Controller - The Officer in charge of all operations of the tactical control center. He is responsible to the tactical Air Commander for the control of all aircraft and air warning facilities within his area of responsibility.

Tactical Air Control Center (TACC) - The principal air operations installations (land or sea base) from which all aircraft and air warning functions of a tactical air command are controlled. The Tactical Air Control Center is the operational component of the tactical air control group operating at Army or Amphibious Forces level.

Tactical Air Direction Center (TADC) - A subordinate air operations installation (land or sea based) from which all aircraft and air warning operations within a restricted area are directed. The Tactical Air Direction Center is the operational component of a tactical air control group operating at corps level or amphibious group level.

Tactical Air Control Group - (Land-Based) A flexible administrative and Tactical Component of a Tactical Air Force which provides aircraft control and warning functions ashore for offensive and defensive missions within the Tactical Air Force area of responsibility.

Tactical Air Control Party (TACP) - A subordinate operational component of the land-based Tactical Air Control Group designed for the control of aircraft from forward observation posts. The tactical air control party operates at division, regimental, or battalion level.

Theater of Operations - A term used to designate that portion of a theater of war necessary for Military operations, either offensive or defensive, pursuant to an assigned mission and for the administration incident to such Military Operations; theater limits are usually designated by competent authority.

Transport Aircraft - Any airplane designed primarily for the purpose of transportation of material, supplies or passengers.

Troop Carrier Aviation - Air Force Units which are specially organized, equipped, and trained to transport troops and supplies into combat, to re-supply such forces until they are withdrawn or can be supplied by other means, and to evacuate casualties, troops and material.

Troops - A collective term for uniformed Military Personnel (usually not applicable to sailors afloat).

1. (Airborne Troops) - Those troops especially trained to be transported to the combat zone by air and dropped or landed therein.

2. (Combat Troops) - Those units or organizations whose primary mission is destruction of enemy forces and/or installations.

Zone, Drop - A specified area into which airborne troops, equipment or supplies are dropped.

Zone, Landing - A specified zone within an objective area into which gliders or powered aircraft will be landed.

Abbreviations -
1. BCT - Battalion Combat Team
2. COC - Combat Operations Center
3. DCAU - Deputy Chief Air Umpire
4. IFF - Identification Friend or Foe
5. JOC - Joint Operations Center
6. TAC - Tactical Air Controller
7. TACC - Tactical Air Control Center
8. TADC - Tactical Air Direction Center

9. TACG - Tactical Air Control Group

10. TACP - Tactical Air Control Party

11. DZ - Drop Zone

12. LZ - Landing Zone

HEADQUARTERS AGGRESSOR FORCE

EXERCISE "SWARMER"

PHASE I - PLANNING

THIS PAGE IS DECLASSIFIED IAW EO 13526

TABLE OF CONTENTS

THIS PAGE IS DECLASSIFIED IAW EO 13526

CONCEPT
OF
AGGRESSOR'S ROLE IN EXERCISE "SWARMER"

The general mission of the Aggressor Force in Exercise "SWARMER" was to provide training opposition for the United States Forces in their development and build-up of an airhead completely supplied by air. Due to the preponderance of the United States Ground and Air Forces over that of those representing the Aggressor opposition, the latter force assumed more or less the role of a training aid wherein close control was essential. It was emphaized during the planning phase, that Exercise "SWARMER" was not to be a two-soded maneuver and that the Aggressor Force would furnish opposition subject to the direction and control of the Maneuver Commander through the Chief Umpire.

CHAPTER I

Personnel, Organization and Administration

Aggressor GHQ

Representatives of Aggressor GHQ participated in the preliminary planning conference for Exercise "SWARMER" held at Third Army Headquarters, Fort McPherson, Georgia. Planning was based on joint Army - Air Force directive dated 10 December 1949.

A conference was held at Headquarters Maneuver Commander, Exercise "SWARMER", Fort Bragg, North Carolina 13 - 16 February 1950. Representatives of the Maneuver Commander, Aggressor GHQ, Aggressor Force Commander and the 15th Infantry Regiment were present. The General Plan, Exercise "SWARMER" and the Maneuver Control Order, Exercise "SWARMER" were discussed as the basis for detailed planning. Requirements for Army personnel, equipment, supplies, housing and movements for the Aggressor Forces were determined on this basis and a request for their provision was submitted to the Maneuver Commander. (See Appendix # 1, Troop List of Ground Elements of Aggressor Forces, Exercise "SWARMER"). Representatives of the 15th Infantry Regiment were briefed on converting the Army units to be made available into Aggressor Order of Battle and equipping them for the Exercise.

THIS PAGE IS DECLASSIFIED IAW EO 13526

Headquarters Aggressor Forces

On 1 March 1950, Major General Robert M. Lee, Commanding General, Tactical Air Command, Langley Air Force Base, Virginia, assumed command of the Aggressor Forces with temporary headquarters at Langley AFB, Virginia.

The Aggressor Force Headquarters was established at Fort Bragg, North Carolina, in the Field Artillery Replacement Training Center Area on 21 March 1950. (See Appendix # 2, General Order No. , and Appendix # 3, Organizational Chart). The Aggressor GHQ joined as part of Aggressor Force and ceased to function as Aggressor GHQ on 21 March 1950.

A conference was held 23 - 24 March 1950 at Headquarters Maneuver Commander, Exercise "SWARMER", Fort Bragg, North Carolina. This conference was concerned with making arragnements for providing Army personnel to perform the functions of units that had not been made available to the Aggressor Forces and checking all other arrangements to date.

All problems pertaining to personnel and administration had been solved satisfactorily except those concerned with the organization of the Headquarters Aggressor Force. The failure to provide a Headquarters Company made it necessary to requisition sufficient individual commissioned and enlisted personnel to handle the administration and housekeeping of the Headquarters. Personnel were provided from different sources

THIS PAGE IS DECLASSIFIED IAW EO 13526

throughout the Army and Air Force on various dates and were not finally organized until shortly before the tactical phase of the Exercise.

All the Aggressor Force Units were in place at Fort Bragg, North Carolina by 20 April 1950.

15th Infantry Regiment (Reinforced)

Upon receiving notification that the 15th Infantry Regiment was to be the major Army unit of the Aggressor Force to participate in Exercise "SWARMER", action was initiated to secure replacements and obtain logistical support from the 3d Infantry Division and The Infantry Center, Fort Benning, Georgia. Establishment of advance detachments and formation of the Army component in sufficient time to allow participating elements to organise, equip, and train for an Aggressor role became of major importance.

Training in Aggressor tactics was necessary in order to familarize units with Aggressor Tables of Organization. The shortage of Aggressor texts, history, and information pertinent to weapons and equipment, led to direct contactwith Aggressor GHQ at Fort Riley for these materials.

The complexity of the Aggressor mission and organization under Aggressor TO & E's, made it necessary to augment available communications by securing additional signal personnel and equipment. Availability of adequate communications was a

0424

THIS PAGE IS DECLASSIFIED IAW EO 13526

major factor in insuring Umpire Control and in obtaining maximum effectiveness of the Aggressor Forces as a training aid.

Requisitions were submitted for officer and enlisted personnel to bring units up to authorized strength and to insure maximum effectiveness. Some difficulty was encountered in obtaining release of special duty and detached service personnel from post activities. The 3d Infantry Division supplied the replacements for most of these personnel from units not committed to Exercise "SWARMER".

An overseas levy was received for shipment of 63 enlisted personnel of the 3d Battalion, 15th Infantry, which at the time was below its authorized manning level. Special authority was obtained from the Department of the Army to delay shipment of these personnel until completion of Exercise "SWARMER".

Battery "A" 599th Field Artillery was attached by the Third Army to supplement the strength of the 3d Battalion, 15th Infantry in order to organize an Aggressor Anti-tank Company.

Upon arrival in the maneuver area, units had an effective strength of approximately 80% of TO & E strength.

Considerable difficulty was encountered in obtaining authority to publish competent orders for advance echelon and reconnaissance parties. This condition made it necessary to send personnel to Fort Bragg without competent orders. Strength

THIS PAGE IS DECLASSIFIED IAW EO 13526

accounting and obtaining rations for the Advance Detachment was most difficult. In order not to delay the planning of the operation, the Regimental Commander authorized the movement of an advanced detachment to Fort Bragg on Movement Orders. Authority to send advanced detachments was secured at a subsequent date from the Third Army.

Detailed planning and coordination was necessary to provide for the administration of rear detachments at home stations. Sufficient trained personnel to handle discharges, retirements, and separations, remained at Fort Benning.

Units forming the Aggressor Force were attached to the 15th Infantry by two different headquarters, specifing different dates. Considerable confusion existed, in that Headquarters SWARMER, attached units for operation while Headquarters V Corps attached the same units for administration.

17th Explosive Ordnance Disposal Squad

On departure from home station, this unit was at T/O strength, and unit TO & E equipment was on hand. The unit traveled by convoy from Fort Knox, Kentucky, to Fort Bragg, North Carolina. Arrangements were made to bivouac in the National Guard Armory's enroute. Unit consisted of one (1) officer, seven (7) enlisted men and three vehicles. No unusual difficulties were encountered by this unit during Phase I.

THIS PAGE IS DECLASSIFIED IAW EO 13526

Det Signal Sec, 53rd Signal Service Company

Detachment Signal Security, 53rd Signal Service Company, (Army Security Agency) consisting of two (2) officers and twenty five (25) enlisted menwas attached to Headquarters, Aggressor Force, Exercise "SWARMER", by Section V to General Order Number 7, Headquarters Maneuver Commander, Exercise "SWARMER", Fort Bragg, North Carolina, dated 12 March 1950, with effective date of attachment 15 April 1950.

The Detachment was organized from the personnel of Security Monitoring Detachment (UMPIRE) (PROV.), 53rd Signal Service Company, Vint Hill Farm Station, Warrenton, Virginia, and re-designated Detachment Signal Security, 53rd Signal Service Company. The detachment was detached from the 53rd Signal Service Company at Camp MacKall, N. C., on 6 April 1950 and reported to Headquarters Aggressor Force, Fort Bragg, North Carolina on the same date.

ASA Liaison Det

The Army Security Agency Liaison Detachment assigned to Aggressor Forces for Exercise "SWARMER" was activated on or about 1 March 1950 at Arlington Hall Station, Arlington, Virginia, with authorized strength of two (2) officers and nine (9) enlisted men. Arrangements were made for the administration to be handled by home stations of personnel concerned.

0427

Personnel were attached from other organizations for Exercise "SWARMER" only.

162d Tactical Ron Sqdn (Night Photo)

This unit was faced with a personnel problem when assigned to Aggressor Forces, Exercise "SWARMER". Of sixty four (64) officers authorized only thirty eight (38) were assigned and thirty two (32) were present for duty. Eight of these officers were expected to depart within a short period of time on temporary duty or change of station.

1st Shoran Beacon Unit

The 1st Shoran Beacon Unit was alerted in the latter part of March 1950, to participate in Exercise "SWARMER". The Unit was ordered to be operational by 15 April 1950, however, movement orders were not received until 12 April 1950. The unit departed Langley Air Force Base, Virginia, 13 April by government motor convoy. No troubles were encountered enroute and the unit was operational on 15 April 1950.

CHAPTER II

Intelligence

Aggressor GHQ

During the planning conference 9 - 13 January 1950, the J-2, Headquarters "SWARMER", in collaboration with representatives of Aggressor GHQ prepared the general and special situations of Exercise "SWARMER". The Aggressor situation recited the events prior to and leading up to the arrival of Aggressor Invasion Force in the objective area. The history of Aggressor actions in previous campaigns against the United States, and events leading up to the second Carolina Campaign (SWARMER) were prepared in the form of an Intelligence Summary for release to the United States Forces. This summary covered the Intelligence build-up for the Exercise.

During the planning conferences of 13 - 16 February and 23 - 24 March 1950, an Aggressor GHQ representative collaborated with J-2, Headquarters "SWARMER" in preparation of additional Intelligence Summaries with supporting documents and additional Intelligence releases. No particular Intelligence problems developed.

15th Infantry Regiment (Reinforced)

Advance Detail:

An advance detail consisting of the Regimental Assistant

0429

S-2 and Battalion S-2's, the I & R Platoon and two draftsmen were sent from Fort Benning, Georgia, to Fort Bragg, N. C. about a month in advance of the main body of the Regiment. The mission of this detail was to keep the Regimental Commander informed of the developments and to prepare for the commitment of the 15th Infantry Regiment (- 1st Bn) in the role of Aggressor in Exercise "SWARMER". Some of the missions accomplished by this detachment indicate the value of this advance preparation:

1. Made route reconnaissance from Fort Benning to Fort Bragg.
2. Requisitioned Maps.
3. Made visual reconnaissance of the terrain.
4. Prepared Tactical Terrain Study. (See Appendix #4, Tactical Study of the Terrain).
5. Converted Recreation Hall into a "War Room" with large wall maps of the Reservation, and organization charts of the United States Ground and Air Forces, of the Aggressor Forces, and of the Umpire Group. This "War Room" was capable of accomodating over two hundred (200) personnel for briefing purposes.
6. Obtained latest texts and other information on Aggressor History, weapons, equipment, tactics and other information from specialists sent by Aggressor GHQ, Fort Riley, Kansas.

THIS PAGE IS DECLASSIFIED IAW EO 13526

7. Established and maintained liaison with Maneuver Headquarters and Aggressor Headquarters for continuous and current information of interest to the Regimental Commander.
8. Purchased certain items generally not obtainable, i.e. - acetate, grease pencils, plywood and celotex from special funds allocated for Exercise "SWARMER".
9. A rubber terrain model of Fort Bragg Reservation prepared for the Department of the Army and loaned by the 82d Airborne Division added to the interesting collection in the "War Room" and was of considerable aid in early planning for tactical disposition of supporting artillery and anti-aircraft weapons by respective commanders.

Planning at Home Station:

1. Plans were made for converting elements of the Regiment into Aggressor units for the formation of Battle Group "GALLO".
2. Preliminary briefings on Exercise "SWARMER" for the Regimental Commander and Staff and various Infantry School Department Chiefs and Instructors were conducted. Material used was that forwarded from the Advance Echelon at Fort Bragg.

3. The loan of pertinent "vault files" at the Infantry School on such matters as Anti-Airborne Defense, Defense on Extended Frontages and Retrograde Movements was arranged for.
4. Four (4) Aggressor Kits were requisitioned from Tactical Research and New Doctrine, Fort Riley, Kansas. (1 per Bn and Regt'l Hqs)
5. A Regimental CPX using Aggressor designation, symbols, etc., was conducted. COMMENT: (The Regimental CPX revealed lack of familiarity of commanders, staffs and enlisted men in use of Aggressor symbols in the field).

Planning at Fort Bragg:

Upon arrival of main body of 15th Infantry at Fort Bragg, a selection of fifty-three (53) enlisted men was made for Special Duty with the Aggressor POW Detachment. Language qualification was used as the basis for selection.

1. A guide was published for requisitioning of Aggressor uniforms and insignia. (See Appendices # 5 and # 6).
2. Prepared Aggressor Order of Battle Chart, Battle Group "GALLO". (See Appendix # 7).
3. Published Order of Battle on United States 11th Airborne Division and of the 82d Airborne Division.

0432

4. Prepared briefing on Operation Plans of the United States V Corps and of the 82d Airborne Division to include scheduled drops of RCT's and their objectives, "D" Day to "Day" plus 3.
5. Prepared pass forms for security of Regimental Headquarters and War Room. (See Appendix # 8).

THIS PAGE IS DECLASSIFIED IAW EO 13526

CHAPTER III

Operations

Aggressor GHQ

During the planning conference of 13 - 16 February 1950, the matter of the troop list of units of the Aggressor Force ground elements was considered and decisions were made as to availability of those units. At that conference, all requested units were reported available except:

a. One (1) Battalion of Infantry.

b. One (1) Headquarters and Headquarters Company, Engineer Combat Group, or equivalent).

c. One (1) Company, Transportation Truck (2½ ton) with twenty four (24) man augmentation team.

d. One (1) Company, Signal Operation.

It was decided that the Headquarters and Headquarters Company, the Truck Company and the Signal Company would not be available, but that efforts would be made to get other personnel and equipment to handle the functions of those units. Plans were made for the movement to Fort Bragg of the Army units to comprise the Aggressor Force. The Commanding Officer, 15th Infantry Regiment was given advice on reorganizing, equipping and training of the Army units in preparation for the Exercise.

THIS PAGE IS DECLASSIFIED IAW EO 13526

Aggressor Forces

During the conference of 23 - 24 March 1950, it was learned that the Infantry Battalion requested would not be available.

As a result, the requirements for organizing a balanced ground force to play the part of a maneuver enemy could not be entirely met. The Aggressor Force as planned was smaller than is considered desirable for such an Exercise and was not balanced.

15th Infantry Regiment (Reinforced)

The Army component of the Aggressor Force was assigned the mission of providing training opposition to the United States Forces participating in Exercise "SWARMER". The development of this mission began with the planning conferences held at Fort Bragg 13 - 16 February 1950, at which time a broad and general concept was outlined to the Regimental Commander.

A Liaison Group at Fort Bragg, initially representing the 15th Infantry Regimental Commander, was composed of three Officers, - an operations officer, a logistics officer and a communications officer. Subsequent to 11 February 1950, this liaison group was successively augmented on 1, 6, and 21 March by additional increments of staff and operating personnel. The liaison group was responsible for participating in the frequent conferences with Headquarters Maneuver Commander, Headquarters

THIS PAGE IS DECLASSIFIED IAW EO 13526

Umpire Group, and Headquarters Aggressor Forces, resulting in an approved scenario and a detailed Order of Battle. This group was also responsible for:

a. The channeling of information by physical liaison and electrical means to home bases of participating ground Aggressor units in order to facilitate reorganization into the Aggressor Order of Battle.

b. Preparation and submission of requisitions for the Aggressor Force and the physical acquisition and storage of that material.

c. Preparation of billeting facilities at Fort Bragg and preparation of a broad training program for units participating as Army component of the Aggressor Force in "SWARMER".

d. Selection of training areas at Fort Bragg and extensive reconnaissance of terrain available for Exercise "SWARMER".

e. Preparation of a communication plan and pre-maneuver installation of wire circuits.

f. Rendition of logistical support to Headquarters Aggressor Forces.

Some difficulty was experienced in definitely determining the composition of the Army component of the Aggressor Force. The advisability and desirability of obtaining a third battalion of Infantry were discussed at frequent conferences and were still under discussion during the week prior to the closing of the combat team into Fort Bragg on 7 April 1950. If another battalion had been committed to the Army component of the Aggressor Force at that time logistical support would have been difficult to establish. It appeared that an early and definite decision as to the exact composition of the Army component of the Aggressor Force would have eliminated a great deal of discussion and unnecessary delay in publishing a firm troop list.

Difficulty was experienced in the formation and build-up of the advanced detachment of the Army component of the Aggressor Force at Fort Bragg. Individuals were moved in and maintained at Fort Bragg for periods up to three weeks without competent orders fro such movement. Belated written authority from Headquarters "SWARMER" eventually led to the issuance of a confirming order on the movement of an advanced detachment. Early written authorization for the establishment of advance detachments would obviate an appreciable amount of duplication in administration. The desirability of such advance groups is believed justified by the support rendered, not only to parent organizations, but also to higher echelons arriving with insufficient logistical and administrative support.

It should be noted that during a considerable period of the planning time, the Aggressor GHQ and Aggressor Cadre units were participating in PORTREX. A considerable measure of uncertainity as to the exact compostion (Order of Battle) of the

Army component of the Aggressor Force could have been relieved if this overlap had not existed. Early and continuing competent technical advice is of the utmost value in realizing the full potential of Aggressor as the training aid.

At the first planning conference, the problem of achieving adequate mobility for the Army component of the Aggressor Force was discussed. The establishment of a provisional truck company developed as a logical answer to this problem. The implementation of this plan had not been accomplished on 13 April, some two months subsequent to the initial discussion. An early definite and implemented decision on this question would have facilitated planning.

Artillery units were organized under Aggressor TO & E, and received training in Aggressor tactics to include tactical deployment, unit designations, order of battle, uniforms and equipment.

The planning phase for the tank units consisted primarily in effecting a transition from the TO & E under which the units were organized to Aggressor TO & E. This necessitated forming an Aggressor Tank Regiment from a R/T Heavy Tank Battalion plus one Infantry Regiment Tank Company. Because of the shortage of Officer personnel, the two battalion headquarters were designed to fulfill purely tactical functions, and the Regimental Headquarters was utilized to perform logistical and administrative functions for the battalions. Supply, maintenance,

THIS PAGE IS DECLASSIFIED IAW EO 13526

reconnaissance, and transportation sections were kept under regimental control. The chief obstacle to the transition was the shortage of communication personnel and equipment.

Command Post Exercises were conducted in defense of drop zones and airfields. Lack of timely information as to the tactical employment of certain elements of the Aggressor Forces precluded advance training that should have been performed. Operational plans should have been drafted sufficiently in advance to allow extensive training, especially where plans require a major change in organization and tactics.

The anti-aircraft battalion was reorganized to provide one Infantry Company in addition to the normal four (4) gun batteries. This reorganization, together with a shortage of sixteen (16) prime movers, had the effect of employing the four firing batteries at 66% of T/O strength and with 20% normal mobility.

The medical support for the 15th Infantry Regiment (Reinforced) for the Aggressor role in Exercise "SWARMER" consisted of the Medical Company, 15th Infantry Regiment (less one platoon), one platoon of the 618th Clearing Company and one platoon of the 559th Ambulance Company. Immediately upon arrival at Fort Bragg, N. C., the collecting platoon became operational and established a central dispensary for the Aggressor ground troops. Aid stations were established by the battalion medical platoons of the 2d and 3d Battalions,

THIS PAGE IS DECLASSIFIED IAW EO 13526

15th Infantry Regiment, 70th AAA Gun Battalion and the medical section of the 41st Field Artillery Battalion. A central dental clinic was established at the central dispensary and was operated by the Dental Surgeon, 15th Infantry Regiment (Reinforced).

162d Tactical Rcn Sqdn (Night Photo)

A critical shortage existed for qualified Radar Mechanics, Navigation (853); (only two (2) were assigned out of twelve (12) authorized) to perform necessary Shoran maintenance for seventeen (17) aircraft.

The unit was prepared to fly visual and photo reconnaissance, bomber strikes, simulated and/or actual night photography (employing the M56A photo flash bomb over uninhabited areas or D-6 flash which may be employed against any target), intruder, and aerial film drop.

CHAPTER IV

Logistics

Aggressor GHQ

During the planning conference of 13 - 16 February 1950, arrangements were made for the assembly and housing of the Aggressor Force in the Field Artillery Replacement Training Center, Fort Bragg, N. C. and for provision of necessary facilities, supplies, and maintenance of the base camp. In conjunction with representatives of the 15th Infantry Regiment, requirements for equipment and supplies needed for the Aggressor Force were computed and requisitions were submitted. Arrangements were made with the Umpire Group to provide necessary pyrotechnics for fire markers.

15th Infantry Regiment (Reinforced)

Approximately 60 days prior to the date set for Exercise "SWARMER", logistical plans were initiated. Unit commanders were advised of the necessity of completely equipping their units and directed to inspect in order to determine shortages. Requisitions for all shortages were submitted and filled.

One officer and one enlisted man accompanied the advance detachment to Fort Bragg for the purpose of:

a. Establishing liaison with Fort Bragg post supply agencies and working out with the Maneuver Headquarters, the

THIS PAGE IS DECLASSIFIED IAW EO 13526

general supply plan required by the formation of the Aggressor Forces.

b. Establishing requirements and drawing in advance the equipment needed to augment normal TO & E equipment, and items of Post, Camp and Station property required for use at Fort Bragg during the training period preceding the Exercise.

The logistical situation in the 70th AAA Gun Battalion developed in an orderly manner. Excellent cooperation received from the Second Army Service units enabled the battalion to move out with practically all the required equipment. The unit utilized the facilities of Camp Lee during the convoy movement.

A full-field inspection was conducted at home stations prior to movement to the Maneuver area. This method provided the commanders with the necessary check to ascertain the actual condition of supplies, equipment, vehicles, and personnel of the participating units. As a result of such inspections, few emergency requisitions were necessary upon arrival in the Maneuver area.

CHAPTER V

Communication

Aggressor GHQ

During the planning conference of 13 - 16 February 1950, requirements of the Aggressor Force for Signal Corps personnel were presented and discussed. Although the signal operation company requested was not available, arrangements were made to provide the Aggressor Force with part of a Signal Construction Company and certain communication teams from a Signal Service Battalion. The Communications Officer, 15th Infantry Regiment was designated as the representative of the Aggressor Force to work out the requirements for frequencies, wire lines, and other communication matters for the Exercise.

15th Infantry Regiment (Reinforced)

Planning for the communications for the Army components of the Aggressor Force was begun on 13 February 1950. To make possible for the Maneuver Commander and the Chief Umpire to control the maneuver, it was necessary to have complete communication control of the Aggressor Forces. It was evident that steps had to be taken to assemble the necessary personnel and equipment to augment that of the participating Aggressor units. A study was made of the communication personnel and

0443

equipment which were authorized by the TO & E of the 15th Infantry and attached units. Coordinating this with the communication support necessary for the Aggressor Force, alist of augmentation necessary in personnel and equipment was prepared and submitted to the J-5 Section, Headquarters "SWARMER". This list was compared with that of communications troops available for Exercise "SWARMER", and requisitions were prepared and forwarded for the shortage. After a conference with Air Force personnel a list of augmentation personnel and equipment reqired for air-ground communications was also prepared.

A communications operation plan in two parts was prepared. One part was based on authorized personnel and equipment plus augmentation being available and the second authorized personnel and equipment only. These plans were coordinated with J-5, Headquarters "SWARMER."

Difficulty in preparing the communication plan arose in that the tactical employment of the Aggressor Force was not firm at the start of the planning. This made it necessary to formulate a plan that was very flexible. In view of the fact that it would take many man hours to install communication systems this was a definite handicap.

After organizing under the Aggressor TO & E, the chief communication obstacle was the shortage of communication equipment and personnel. To operate all the radio sets which were installed, it was necessary to utilize skeleton crews at each set which was satisfactory only for short periods of time.

24th Signal Service Battalion

During the period 30 March to 13 April 1950, the 24th Signal Service Battalion installed the necessary equipment for the operations of the Aggressor Force Headquarters. One teletype circuit was activated to Langley AFB, and wire circuits for the remaining teletypes were installed and tested pending receipt of equipment for operation.

Four dial trunks were connected to the Fort Bragg switchboard and the line from Fort Bragg switchboard to Langley AFB was extended and patched through to the Senior Operations Officer at JOC. Seven locals were installed in Aggressor Force Headquarters and 10 locals were installed in JOC.

A SCR 399 was set up and tested. A radio schedule was arranged with the Navy at Norfolk but no contact was established. Ten telephones were installed in JOC and the lines laid to remote Control Radio Equipment. Fifteen additional locals were laid.

Cryptographic personnel were assigned to work for the Aggressor Force Crypto Officer. The lack of training in the system which was used was a big obstacle to good operation.

Aggressor Headquarters

The communication section got off to an extremely slow beginning, because of the relatively small amount of information

THIS PAGE IS DECLASSIFIED IAW EO 13526

available concerning the scope of the maneuver, the units comprising the Aggressor Force, where those units would operate, and details of their operation. Without this information, it was difficult to anticipate the communication systems required. Some of the commercial requirements were requested late because of the addition of extra units and because some committments previously made were withdrawn.

The communications section was comprised of three officers; two to oversee operations at Aggressor Headquarters, at JOC, at TACC, and at all subordinate units, and one officer to supervise the message, and crypto-security centers. This arrangement of personnel worked satisfactorily, but was made too late. For a period of about three weeks, one officer was assigned this duty but was unable to devote more than two days each week because his primary duty kept him at Langley AFB. Some of the last minute requests for facilities might have been eliminated if the section had been up to strength and had more time to secure information for planning.

In this type of maneuver high mobility of Aggressor Force is necessary. Communications depends entirely on communications, it should also be of the best. Must be adequate and flexible. More planning time than was allowed in this maneuver is absolutely necessary.

Communication Center

No crypto officer was provided for Aggressor Force Head-

THIS PAGE IS DECLASSIFIED IAW EO 13526

quarters until two weeks prior to the Maneuver. Only three crypto technicians were assigned to crypto (2 Pfc's and 1 Pvt). None of the three had valid crypto clearances, but all had undergone a Partial Background Investigation. Only two of the three had operated SIGROD, one had no experience with the M-209, and another had no experience with strip systems. None had been assigned to a regular crypto unit prior to the Maneuver, and not one could change a safe combination. They had not read the crypto instructional books required of all cryptographers prior to operation of the particular systems held by the Aggressor Force.

Due to the lack of tape cutting equipment and patch panels, at Aggressor Force Headquarters all teletype messages had to be sent by hand, and operations reports (which were up to 14 pages in length with four addresses) had to be sent on two different circuits.

THIS PAGE IS DECLASSIFIED IAW EO 13526

CHAPTER VI

Conclusions and Recommendations

The supporting troops and various attachments to the Aggressor Force should be made known as early as possible to the Aggressor Force Commander so that he may prepare his tactical organization, training schedules, and tentative operation plans for the employment of forces that he can expect to be made available.

An operations plan or scenario should be forthcoming from Maneuver Headquarters at the earliest possible time after the designation of the Aggressor Force to participate in the exercise. Without such a directive, the Aggressor Force cannot publish a plan and subordinate commanders are forced to initiate wha action they deem practicable without knowing the requirements or policy of higher headquarters. The delayed issuance of such a directive can only result in confusion and possible changes to instructions previously announced by commanders of subordinate elements when found to be in conflict with those of higher headquarters published at a later date.

It is the considered opinion of this headquarters, that the Aggressor Force Headquarters should be established early in the planning phase in order to avoid the necessity of subordinate units maintaining liaison with numerous

THIS PAGE IS DECLASSIFIED IAW EO 13526

higher headquarters during the planning phase. The establishment of the Aggressor Force Headquarters early in the planning phase would eliminate duplication of effort and permit the maximum of efficiency.

It is believed that troops representing the Aggressor Force should close in the Manuever Area at least thirty (30) days but preferably six (6) weeks prior to the beginning of the maneuver. This will permit sufficient time for completion and issue of plans, emplacement of weapons, preparation of positions, and actual training on the ground. If at all possible, Aggressor Force troops should have unrestricted access to the objective area during this period in order to plan and rehearse the tactical play for the exercise.

A fair and equitable portion of SFE funds should be made available to the Aggressor Force Commander at an early date in order that necessary supplies and special equipment considered necessary for the efficient conduct of the maneuver may be purchased.

To insure a clear and definite concept of the Aggressor role in the operation, and early conference between representatives of the Maneuver Commander's Joint Staff, Umpire Group, Aggressor GHQ, and the troop units comprising the Aggressor Force is considered essential. This liaison should be established at an early date and be continuous throughout the planning, training, and tactical phases of the exercise.

This procedure would afford a logical and conclusive concept whereby all participating levels would be in accord as to the excat mission confronting the units representing the Aggressor enemy.

It is the opinion of this headquarters that much benefit would be derived from the assignment of Aggressor GHQ personnel to assist in the training of Aggressor ground units at least forty five (45) days prior to the commencement of the maneuver.

For efficient and complete planning, it is considered essential that authority be granted the commander of the Army component to provide adequate advance detachments under competent orders.

Because of the fact that Exercise "SWARMER" followed so closely after the termination of Operation PORTREX, with overlap of the planning phase of the former and the preparatory tactical and re-deployment phases of the latter, full benefit and assistance could not be reasonably expected from Aggressor GHQ. It would appear that due to the close timing between these two operations, it was necessary to resort to substitution of certain units and delay in furnishing training aids and equipment to the Army units alerted for the Aggressor Force, Exercise "SWARMER".

THIS PAGE IS DECLASSIFIED IAW EO 13526

HEADQUARTERS
MANEUVER COMMANDER
EXERCISE SWARMER
Fort Bragg, North Carolina

15 February 1950

SUBJECT: Troop list of Ground Element Aggressor Force, Exercise Swarmer.

TO: Maneuver Commander
Exercise Swarmer
Fort Bragg, N. C.

1. References:

a. Department of the Army-Department of the Air Force, Directive of Joint (Army-Air Force) Exercise, FY 1950, dated 10 December 1949.

b. Army Field Forces Publication, Exercise Swarmer, 2 February 1950.

c. D/A Field Manuals, F.M. 30-101, 30-102, 30-103, 30-104, and 105-5.

2. In order to play effectively its part as the maneuver enemy, it is recommended that the Aggressor Force for Exercise Swarmer be provided the following listed numbers and types of units:

a. One (1) regiment of infantry, less one (1) battalion.

b. One (1) battalion of infantry.

c. One (1) battalion of field artillery, light.

d. One (1) company of combat engineers.

e. One (1) battalion of tanks, heavy.

f. One (1) battalion of anti-aircraft artillery.

g. One (1) Headquarters and Headquarters company, engineer group or equivalent.

h. One (1) comapny, signal operations

i. One (1) company, transportation trucks, (2½ ton) with 24 men augmentation team.

j. One (1) company, ordinance medium maintenance.

k. One (1) platoon, medical ambulance company.

l. One (1) platoon, medical clearing company.

m. One (1) platoon, military police company.

ANNEX #1

THIS PAGE IS DECLASSIFIED IAW EO 13526

n. One (1) platoon, quartermaster service company.

o. One (1) platoon, quartermaster petrol company.

p. One (1) platoon, ordinance ammunition supply company.

q. One (1) counter-intelligence detachment.

r. One (1) MI order of battle Team.

s. One (1) MI photo interpretor team.

t. Four (4) MI Interrogation of prisoners of war teams.

u. Aggressor GHQ units as follows:

(1) Aggressor GHQ

(2) Hq & Hq Det, 47th Engr Com Bn

(3) B Company, 47th Engr Com Bn

(4) Signal Co (Special) 23rd Hq Special Troops

(5) Tactical Information Detachment

v. Of the units listed in sub-paragraph above, B Company, 47th Engr Com Bn is presently at Fort Riley, Kansas. Other units are presently participating in Exercise PORTREX. A Company, 47th Engr Com Bn, similar in composition to B Company, is presently participating in Exercise PORTREX.

3. The above troop list is predicated upon the following assumptions:

a. That the Aggressor Force for Exercise SWARMER will be assembled at Fort Bragg, N. C.

b. That the Aggressor Force during the pre-maneuver training phase will be housed in a base camp in cantonment buildings at Fort Bragg, N. C.

c. That the base camp will be maintained until departure of units from Fort Bragg, N. C.

d. That the ground units of the Aggressor Force will move from the base camp to bivouacs in the maneuver area at such times as required during the pre-maneuver and tactical phases of the Exercise.

e. That because of the small size of the Aggressor Force, and the wide frontages and great depths of terrain over which this force will have to operate, all units must be motorized.

THIS PAGE IS DECLASSIFIED IAW EO 13526

4. The troop list given above will permit the Commander, Aggressor Force to provide adequate representation of the ground elements of his force, and to support them administratively during the pre-maneuver and tactical phases of the Exercise. The ground elements of the Aggressor Force would be organized so as to represent the units shown on the attached chart (Incl #1).

RESTRICTED

TACTICAL STUDY OF THE TERRAIN

a. Fort Bragg.

(1) The reservation at Fort Bragg is generally pear-shaped with the stem pointed to the east, and its center located at 79° 10' 31" W-35° 6' 31" N. The east-west axis is approximately 24.2 miles, and the north-south axis is approximately 11.9 miles at the widest part.

(a) Drainage system. James Creek flows into the Little River and forms the northern boundary of the reservation. A ridge line extends generally through the east-west axis forming a water shed and causing the streams to flow to the north and south. Numerous wet weather streams and small creeks, with an occasional lake, are distributed at regular intervals on the north and south of the water shed.

(b) There is a main ridge line extending generally through the east-west axis with numerous projections to the north and south. There is a second prominent ridge in the southwestern part of the reservation. The highest elevation is approximately 500 feet, and the lowest about 150 feet.

(c) Highways and roads. Three main third class roads extend from Fort Bragg west through the reservation; Manchester Road generally through the center; and Plank Road along the southern boundary. Several dirt roads extend north and south across the reservation forming an excellent network of dry weather roads.

(d) General nature of the Terrain: The terrain is generally rolling and wooded with the heaviest wooded area along the streams. The highest elevation is along the southwest boundary, and center of this area. The lowest elevation is at Pope Field. . .

(2) (a) Avenues of approach and lines of communication: Troops can approach Fort Bragg from any direction. The best route of approach from the west would be along the east-west ridge line.

(b) Obstacles: There are no major obstacles in the area in dry weather. All streams except Little River are fordable. In wet weather motorized units would experience some difficulty in traversing this area due to dirt roads and numerous stream crossings.

(c) Concealment and cover: Cover seems to be generally good-with areas along the streams and creeks providing the best cover.

(d) Observation: Ground observation is good.

(e) Field of fire: Generally 360° of fire exist for all weapons; ideal artillery positions are sometimes difficult to find.

RESTRICTED

ANNEX #4

TACTICAL STUDY OF THE TERRAIN (CONT)

(3) Critical terrain features: The highest elevation is along the extreme southwest boundary. Railroad Ridge, Johnson, Blues, Gaddys, and Coolycoach Mountains are considered critical points in this area.

(4) Tactical effect of the terrain: The terrain in this area is such as to facilitate military operations.

b. Camp Mackall.

(1) Camp Mackall is located 7 miles southwest of Fort Bragg reservation and is separated by a corridor approximately 6 miles wide. The camp itself has no describable shape.

(a) Drainage systems: The area is drained by three main streams; Browning Creek, Swan Creek, and Browning Creek. Numerous other small streams and wet weather streams are distributed throughout the area.

(b) There are two prominent hills and one ridge in the northwest portion of the area. Highest elevation is about 550 feet and the lowest about 250 feet.

(c) Highways and roads: U.S. Highway 1 and the Seaboard Air Line Railway runs through the center of the area from north to south. State Highway 15 and 501 extend through the western portion of the area on a north-south line. Numerous dirt roads and trails form an excellent network of dry weather roads over the entire area.

(d) General nature of the terrain: The terrain is generally rolling and wooded. Most of the area consisted of small farms prior to the time it became a reservation.

(2) (a) Avenues of approach: Troops can approach from any direction. The rolling terrain is adaptable to any troop movements.

(b) Obstacles: There are no major abstacles of note.

(c) Concealment and cover: Cover is generally good. Concealment is thin and spotty in some locations.

(d) Observations: Ground observation is fair.

(e) Fields of fire: Generally 360 degrees of fire exist for all weapons.

(3) Critical terrain features: The critical terrain features are the Sandhills area. The remaining terrain is of such nature as to cause it to be neither critical or vital.

(4) Tactical effect of the terrain: The terrain in this area is such to facilitate military operations.

Fort Bragg, N. C.

15 April 1950

INTELLIGENCE MEMORANDUM

TO: All Units.

1. SECURITY: a. Yesterday two suspected agents entered the GALLO area, one posing as an inspector of Mess-Halls and the other as a civilian photographer. The "Inspec tor" was apprehended, delivered to GALLO Intelligence Officer and processed, while the other was merely told to get a clearance from Headquarters and promptly escaped. It is repeated that suspects be taken to local Intelligence Officer for processing or clearance.

b. A pass system for personnel authorized to enter this Headquarters is in effect. Subordinate units will adopt a local pass system of their own, to be limited to entry of CP's and vital installations.

2. INSIGNIA: a. Some slight changes have been made by Aggressor Headquarters to the uniform insignia published in Memorandum dated 10 April. The correeted insignia is as follows:

Unit	Collar Tabs Color	Collar Tabs Numeral	Sleeve Insignia Color	Sleeve Insignia Numeral
Organic Els 62 Rifle Regt	Red	62	Red	12
134 Arty Regt	White	134	Red	12
614 Tank Regt	Yellow	614	Red	NONE
691 AA Regt	White	691	Red	NONE
112 Engr Co	Black	112	Red	12
Service Elements - 112 Sv Bn	NONE		Red	12
AT Co, 112 AT Regt	White	112	Red	12

b. Collar tabs and sleeve insignia will not be worn until 240001 April 1950, when the situation becomes TACTICAL.

3. AGGRESSOR WEAPONS: Weapon characteristics and performance listed on page 146, FM 30-102 will be credited by Umpires. Unit commanders should be aware of the support of such weapons as 120-mm artillery pieces, 80-mm AA guns in ground support, and 105-mm AT guns. The tank gun (US 76-mm) will be credited as AGG 90-mm tank gun. Performace of the 80-mm AA gun, NOT listed in the above FM, is as follows:

Maximum ceiling	40,000 feet
Maximum horizontal range	19,000 yards
Muzzle velocity	2,950 ft/sec

4. AGGRESSOR NAMES: a. In order to get both officer and enlisted personnel familiar with the Aggressor names of commander and staff members, assigned names will become effective upon movement to the field 19 April 1950. They will be used throughout the tactical situation.

b. A limited distribution of the Aggressor O/B including both U.S. and Aggressor names will be published soon.

c. An Aggressor identification card overstamped with "Exercise SWARMER" will be issued to each officer. The Aggressor name shouls be entered in print, and "authenticated" by the officer's own signature.

TABLE OF CONTENTS

THIS PAGE IS DECLASSIFIED IAW EO 13526

INTRODUCTION

Upon arrival in the Maneuver Area, Units assigned to the Aggressor Force became the training responsibility of the Aggressor Force Commander. Under the direction of Headquarters Aggressor Force, the unit commanders completed the necessary arrangements for the administration and tactical preparation of their units for participation in the Exercise.

Action was taken to accomplish: Orientation briefings and demonstrations on Aggressor techniques and equipment; reorganization and equipping of United States Units under the Aggressor Order of Battle; and instruction in Aggressor history; organization and uniforms, and the Operations Plan, Aggressor Force.

Action was taken to accomplish: The reconnaissance of the objective area to locate the key terrain features and routes, and to determine the time and space factors; Instruction of specialists for operation of special Aggressor equipment and employment of special Aggressor techniques; preparation of detailed tactical plans, and the walk through and rehearsals of these plans.

Action was taken to accomplish: Instruction of Army units in function of joint Army - Air Force control activities such as JOC, TACC, TADC, TACP, and SHORAN; instruction of air units in the tactical operations to be conducted by ground units, and rehearsals of joint Army - Air Force operation.

Action was taken to accomplish: Preparation and occupation of service area installations; preparation and occupation of defensive positions, weapons emplacement, CP's and other forward area installations;

distribution of supplies; and implementation of the pre-maneuver phase of agent play, psychological warfare play, and tactical radio net play.

Detailed discussion of the above matters are covered in the following chapters.

CHAPTER I

Training

The Aggressor GHQ and Cadre Units conducted, during the pre- maneuver training phase, two hour orientation briefings and demonstrations for interested personnel of the Umpire Group, 15th Infantry Regiment (Reinforced), and Tactical Air Command and Air Force and Naval Air Units of the Aggressor Force. These presentations took place 31 March, 7 - 12 April, and 17 April 1950 respectively and included discussions of the "Why of Aggressor", and "What Aggressor Does and How it is Done"; and demonstrations of "What Aggressor Uses and How it is Used".

A group of specially selected personnel of the 503rd CIC detachment under the CIC Officer of this Headquarters, were given training to prepare them to play the part of Aggressor Agents against the U.S. Forces. Each agent was furnished identification and other Aggressor documents and drilled in a cover story. They reconnoitered sensitive areas of selected installations of the U.S. Force and made plans for the clandestine penetration of such areas in various disguises. Each agent was given the overall missions of testing the security of the U.S. Forces and securing information of intelligence value to the Aggressor Force. Some agents were given the additional mission of distributing subversive propaganda, and others to execute sabotage. During the period 10-20 April restricted agent play was conducted against the U.S. Forces to test their security, secure information and distribute propaganda (See Annexes 1 thru 4). Beginning with 21 April, agent play was unrestricted, so sabotage missions were included.

The Detachment of the 525th MI Serv Platoon, under the IPW Officer of this Headquarters, prepared cover stories and documents for use of Aggressor prisoners, casualties, and deserters. Based on the tactical plan of the Aggressor Force, a schedule for the release of prisoners and documents was prepared. During the period 10-26 April, a group of fifty enlisted men furnished by the 15th Infantry Regiment (Reinf) were given training to prepare them to play the part of the Aggressor prisoners, casualties and deserters to be released to the U. S. Forces during the tactical phase of the Exercise.

The Tactical Information Detachment prepared psychological warfare documents for distribution to the U. S. Forces during the training and tactical phases of the Exercise. Reconnaissance was made of the objective area and plans were made for the projection of loudspeaker propaganda broadcasts during the tactical phase.

The Signal Company (Special) Headquarters, 23rd Special Troops prepared and mounted sonic equipment, and trained eighteen enlisted men of the 15th Infantry Regiment (Reinf) to operate large and small sonic units during the tactical phase of the Exercise. Reconnaissance was conducted in the objective area, and plans were made for the employment of the large sonic units with the fire marking teams, and the small sonic units with the infantry battalions. Rehearsals were conducted with the organizations to which attached.

Personnel of "A" Company, 47th Engineer Camouflage Battalion trained selected personnel of the 15th Infantry Regiment (Reinf) in the operation and maintenance of artillery flash simulators and assisted in the preparation of dummy positions and emplacement of flash simulators and pneumatic targets for deception purposes.

The Artillery Staff Officer of the Aggressor Headquarters directed and supervised the field training of Fire Marking Teams assigned to the Aggressor Force, and advised the Commander, Group CAILO Artillery in the employment of Aggressor techniques for indirect fire weapons. The G-2 and G-3 Staff Officers engaged in joint training exercises in the Joint Operations Center in the preparation for performing duties with the JOC during the tactical phase of the Exercise.

A Detachment of the ASA established and operated a simulated Aggressor tactical radio net, over which was transmitted, in a special code, certain messages that included information of intelligence value to the United States Forces. A specially equipped ASA team reconnoitered the area to be used by the United States Forces to locate sensitive points for using wire intercept equipment. An ASA radio monitoring team monitored radio traffic of the United States Forces to detect violations of transmission procedures and infractions of communications security.

The Military Government team of the Aggressor Force prepared documents for use in the Exercise. (See Annexes 4 thru 17)

The training phase for the 15th Infantry Regiment and all units attached to it began upon arrival in the Maneuver Area. Essentially, the training resolved itself into two main phases; the reorganization into Aggressor Components, and the rehearsals of the appropriate

Aggressor mission. Administrative personnel were required to attend Aggressor orientations and demonstrations in order to become familiar with Aggressor organization, weapons and tactics.

Special emphasis was placed on prisoner of war training, (including interrogation) order of battle and guerilla tactics. Units were instructed in security of military information and counter intelligence measures. Numerous briefings and orientations were held for Umpires and Aggressor Force Commander based upon information received concerning plans of the opposing forces. Timely information as to plans of the United States Forces assisted in formulating the Aggressor Operational plan with a view toward affording U. S. Forces a maximum of opposition with a minimum of personnel.

Training was also conducted on tactics, communications and camouflage; reconnaissance of maneuver area; tactical employment and normal missions of a tank unit, AA gun unit and combat engineer unit; daylight and blackout convoy movements; and organization of defense positions and night displacement.

THIS PAGE IS DECLASSIFIED IAW EO 13526

RECOMMENDATIONS

Units designated to participate in the Exercise as part of the Aggressor Force be assembled in or near the objective area four to six weeks prior to the start of the tactical phase.

oooooo

Orientation briefings and demonstrations by the Aggressor GHQ and Cadre Units be presented to all personnel of the Aggressor Force shortly after its assembly, and before other training starts.

oooooo

Personnel to be trained as specialists in the operation of special Aggressor equipment, or for employment of special Aggressor techniques, be made available for instruction shortly after the Aggressor Force is assembled.

oooooo

All special items of equipment and supplies required to equip the Aggressor Force be available at the time and place the Aggressor Force is assembled.

oooooo

Until they leave their home stations, units of the Aggressor Force continue training under current programs, so modified as to include subjects considered essential in preparing for the type of tactical operations to be conducted in the Exercise.

oooooo

When the Aggressor Force is assembled four weeks or more prior to the start of the tactical phase, training in most Aggressor subjects be conducted after the arrival of the Aggressor GHQ and Cadre Units with their instructor personnel and special equipment.

******

CHAPTER II

Operations

Personnel continued to present a problem to the 162nd Tactical Reconnaissance Squadron, Night Photographic. The unit had five and one-half ($5\frac{1}{2}$) complete crews available for operational work during the training phase. In order to meet the flying committments, crews had been reduced by one navigator, making eleven (11) skeleton crews available for operations.

During the training phase, the Unit flew photo reconnaissance, shoran pinpoint, and aerial film delivery missions. Equipment difficulties plus the weather conditions precluded complete success on the Shoran missions which were assigned to the unit. Continuous maintenance on radar equipment is necessary to eliminate repetitive malfunctions.

The 1st Shoran Beacon Unit computed the five (5) Shoran missions flown by the 162nd Reconnaissance Squadron. Although one (1) of the missions was reported completed, it was later reported as unsuccessful because of camera malfunction. One mission was entirely aborted, and the other missions were unsuccessful because of insufficient training of the Shoran Navigators. All failures were found to be in the airborne sets and were caused by the Navigators not having sufficient training in this special set.

As experience has shown, in order to keep abreast and ahead of expectations from Higher Headquarters, sufficient targets were computed and forwarded to the Joint Operations Center in order that there would be no delay in the time of requesting and receiving a missions computation. The targets consisted of Aberdeen Airport, Bennetsville Water Tower, Dillon Water Tower, City of Southern Pines, Ranger Station and Water Dam at Fort Bragg, Maxton and Marshalling Yard at Maxton.

Aggressor Force Joint Operations Center and Tactical Air Control Center building was set up by the 502d Tactical Control Group. JOC started 24 hour day operations on 16 April 1950. Since no personnel experienced in JOC operations were assigned to the Aggressor JOC, arrangements were made with TAF, whereby representatives of the Headquarters presented briefings on administrative details and record keeping pertaining to JOC operations.

This training period was sufficient to train personnel, coordinate with the subordinate units, and work out details of operation. Orientation missions were laid on for 17, 18 and 19 April and training missions were scheduled 20 through 23 April. For breakdown of missions and sorties flown during this period and their results, Table No. 1.

Communication was the most unsatisfactory part of the operations of the JOC. Poor planning and poor results were evident.

In compliance with verbal instructions from Aggressor Force Headquarters, the 31st Fighter Group (Fighter-Bomber) participated in flying training from 16 thru 23 April. During this period, Squadrons of the 31st Fighter Group participated in a scheduled two - one and one half hour sorties per operational aircraft per day. Missions flown included normal unit formation, tactics, and area familiarization flights. These

0474

THIS PAGE IS DECLASSIFIED IAW EO 13526

were made from Langley AFB to the Fort Bragg, MacKall and Maxton-Laurinburg areas. Inaddition, training flights were conducted in conjunction with the Tactical Air Control Center, the Tactical Air Direction Center and a Forward Air Control Party.

The training phase for the Naval Unit of the Aggressor Force participating in the Exercise commenced on 15 April 1950. The Unit, composed of eight (8) F4U5N, four (4) AD-2Q, and one (1) P2V type aircraft, progressed smoothly through the training period which consisted of night area familiarization, night tactical work such as intercept missions, intruder missions, and night strikes.

None other than normal problems incident to operations away from home station were encountered. Some difficulties were caused by late receipt of directives and operational orders.

TABLE NO. 1

TYPE	NUMBER SCHEDULED	NUMBER RUN	RESULTS
Photo Reconnaissance	35	32	25 Successful
Night Intruder	10	5	3 Successful
Bombing Day and Night	1	0	0 Successful
Strafing	0	0	0 Successful

CHAPTER III

Logistics

The 15th Infantry Regiment furnished logisitical support to all attached army units, and established POL distribution points and field supply dumps. The primary difficulty throughout this entire period was the requirement for processing and unnecessary large number of individual requisitions and resulting issues. This factor over-burdened clerical facilities of both regimental and post supply agencies, causing bottlenecks which in turn wasted manpower and transport. Had innumerable small requests been planned ahead and consolidated by units, a considerable ease of operation would have resulted.

A number of Aggressor Force units arrived in the Maneuver Area in short supply; In some cases entirely without certain expendable supplies (TA 10-100) that should have been brought from home stations. Some individuals, particularly those who arrived and joined their units in the Maneuver Area, where without proper clothing and equipment.

These deficiencies resulted in numerous requisitions that would have not been necessary had instructions published by SWARMER Headquarters been followed in this matter.

Aggressor uniforms and insignia were difficult to get in proper quantities. An excess of extremely small sizes was available but properly fitting Aggressor uniforms were not available.

0476

THIS PAGE IS DECLASSIFIED IAW EO 13526

CHAPTER IV

Communications

Actual training of a limited amount was accomplished by the communication units that were operational during this period, with the exception of the 9466th TSU, and an HF Radio Unit which were committed to the Aggressor Force on the 19th April and were not operational during the training phase.

The time allocated to the training phase was used more for planning purposes than for training because of the late period that the Communications section was initiated in this Exercise.

On 22 April 1950, another direct telephone trunk line was installed from the Maneuver Headquarters to Aggressor Force Headquarters to alleviate the exceptionally heavy amount of traffic between these two points.

Army Security Agency and other crypto planners attempted no overall plan for providing adequate crypto facilities for all participating units in the Maneuver. What was planned, such as composite holders charts, was incomplete and artificial. The crypto material was simply "dumped" on the Aggressor Headquarters custodian to be disposed of as he saw fit. In two weeks time he was expected to set up his own crypto facility to handle traffic for Aggressor Headquarters, JOC and TACC Aggressor, and for the various Air Umpires. In addition, he had to determine as best he could which outfits were Aggressor units, who were the properly cleared custodians at each unit, what systems should be utilized at each unit, and the required indoctrination of personnel at each unit.

Maneuver and Umpire manuals proved not merely ineffectual on classification problems, they were misleading, confusing, and were not conducive to security in general. As a consequence, much crypto material was passed out to custodians of questionable reliability. As far as can be determined, encrypted Aggressor traffic passed only between Aggressor Headquarters and MANCOM. Not once did a crypto man at Langley or Norfolk encrypt its so-called Swarmer Secret traffic. The Manuals did not mention Confidential classification or low precedences; consequently, all units marked their traffic "Secret" and then sent it Priority or Operational Priority in clear text. They also made free use of the telephone for bogus Secret traffic, and often left it unattended for free observation by unauthorized personnel.

Only after the Training Phase began was the Communications Center informed that tactical maneuver traffic could not use world-wide nets. Nearly every message went to both Langley and Norfolk, but both were not on a common net. Consequently, messages had to be sent over two M-15 machines simultaneously. Ops reports up to twelve and fourteen pages, classified Secret and showing OP precedences, could not be partically transmitted by two crypto clerks using the M-209 Converter or other low grade systems which were authorized for use. Efforts to secure a Class "A" system from Langley AFB and Norfolk ended in failure. The only reply from A.S.A. was to "break the messages into two parts and put and operator on each part".

Since practical common systems were not held by major Aggressor units, very little training was possible. Two clerks at Aggressor Headquarters got their first training in accounting for crypto material, in answering violation reports, and in use of systems not known to them previously. United States Force intercept teams obviously had fruitless hours of waiting for traffic that did not appear.

The establishment of a communication plan to fit the operational plan of the 15th Infantry Regiment (Reinforced) presented some difficulty because of the shortage of personnel and equipment. The communications system was considered excellent in its overall plan and proved the value of prior planning and intensive training. The actual radio net organization was established well in advance, and personnel were given training at their actual locations in the maneuver area.

RECOMMENDATIONS

Units participating in the Exercise should be determined at the earliest possible date. This list should be turned over to the J - 5 Section of the Maneuver Headquarters. J - 5 Section should then provide for one Class "A" and one reserve crypto system at each base or post participating. J - 5 should also indoctrinate and assign such personnel as will be required at each crypto unit to perform crypto duties for all parties of either side requiring crypto duty.

******

Smaller units should have Class "B" systems - never more than one - and an enlisted man operator for each unit would be sufficient. These enlisted men would be directly under J - 5, and attached for the crypto duty, then a Holders Chart would be unnecessary, and duplicate sets of Maneuver systems would be unnecessary. Furthermore, classified traffic would get the properclassification rather than haphazard and insecure treatment.

******

Double classification of Maneuver traffic should be eliminated. If theclassification of Secret is necessary at the time of transmittal, the message can easily be downgraded to Restricted or unclassified upon completion of the Exercise in accordance with existing directives. Military personnel safeguard Secret matter; they give Maneuver Secret an unclassified treatment. Manuals should not require every Maneuver document to be secret nor of Operational precedence. Current directives

THIS PAGE IS DECLASSIFIED IAW EO 13526

also cover this subject.

******

Proper clearance for custodianship of crypto material should be a J-5 function and all crypto personnel sent out by J-5 would assume such crypto custody as required for his particular needs. Then all systems would be used as necessary at all stations by experts.

Messages which must be telephoned should never be classified. Experienced crypto personnel would not thus comprise crypto security, and should be a party in overall communications planning. Classified traffic not in use should be stored securely by the Secretary of the Crypto Officer.

******

Subordinate Aggressor units should be put on a common teletype net with Aggressor Headquarters, and tape transmission should be provided at least for the Headquarters unit.

HEADQUARTERS
MANEUVER COMMANDER
EXERCISE SWARMER
Fort Bragg - Camp Mackall
North Carolina

CRITIQUE

At 0800 hours on 5 May 1950, the commanding generals and high ranking officers connected with the maneuver, Exercise Swarmer, gathered together in the building occupied by Umpire Headquarters at Camp Mackall for a summary of events. Lt Gen Norstad opened the session by welcoming the officers to this second part of the maneuver, and giving the order of events scheduled. The commanding general of each force was given an opportunity to speak and present the high points of the maneuver from his particular viewpoint. Recommendations were made as to how future maneuvers of this type might be improved. For the purpose of further reference and study, the remarks of each speaker are hereby incorporated into the final maneuver report.

Maneuver Commander
Lt Gen Lauris Norstad, USAF

Umpire Group
Brig Gen Gerald J. Higgins, USA

Aggressor Forces
Maj Gen Robert M. Lee, USAF

Task Force Swarmer
Lt Gen John R. Hodge, USA

Brig Gen W. R. Wolfinbarger, USAF

Carolina Base Section
Brig Gen Paul F. Yount, USA

COMMENTS BY BRIG GEN GERALD J. HIGGINS, CHIEF UMPIRE

It is my plan, in the limited time available, to present a chronological report on the maneuver, beginning with preliminary air operations and ending with the coordinated ground assault on Fayetteville airport. I will intersperse certain comments and observations on particular actions where appropriate, and furnish certain statistical data where necessary. My summary will reflect, in general, the consensus of opinion of senior air, airborne and ground umpires who have closely followed the exercise from inception to conclusion. It is hoped that commanders concerned will accept critical remarks in the same vein in which they are offered--an honest desire on the part of the Umpire Group to assist in our country's preparedness by correcting weaknesses and mistakes as indicated by performances of individuals and units during the actual maneuver. Many points are highly controversial, of course, and arguments may well be in order. However, in most cases such arguments boil down to whether or not the enemy has certain capabilities, and we in the Umpire Group feel that our mission will be accomplished if we can bring such controversies to the attention of those charged with the planning and execution of future operations to the end that adequate provision will be made to cope with such enemy capabilities.

I am assuming that all of you are familiar with the background of this exercise, and therefore I will not spend time on preliminaries and events leading up to the launching of Airborne Operations Swarmer. In order to save as much time as possible, I have asked Colonel Leahy to assist me by indicating on the maps the play of the exercise in chronological order.

On April 15th United States Air Forces began flying photo reconnaissance missions; an average of twelve missions per day were flown for the next nine days.

D-day - 4:

The war proper began on 24 April 1950. Aggressor committed the overt act by raiding the U.S. Forces field at Laurinburg-Maxton at 0001, 24 April 1950, and continued throughout the day for a total of twenty two missions; U.S. Air Forces flew a total of sixty missions. The number of sorties, of course, was much higher. The air umpire staff is of the opinion that on this date the United States Air Forces violated accepted tactical doctrine, in that they applied too much of their strength against Phase II targets, i.e., ground objectives, before a high degree of air superiority had been attained. Umpire records indicate that on this date 57% of United States Air Forces effort was devoted to Phase I missions, and 43% to Phase II missions.

D-day - 3:

On the following day, April 25, the United States Air Forces quickly reversed this policy and applied 81% of their Air Force to missions designed to gain air superiority. The umpire figures clearly indicate

0487

that the considerable number of losses suffered by United States Air Forces could have been reduced by decisively employing aircraft in gaining air superiority before applying air strength to battle field objectives.

On this date, April 25th, United States Air Forces flew a total of 41 missions, and the Aggressor flew 9. On the evening of April 25th the United States Air Forces received actual reinforcement of one fighter group; the group became effective April 26th. The United States Air Forces, due to this reinforcement, and the numerous Aggressor losses, created a situation of air superiority to such a degree that the moving in of airborne troops was considered a good calculated risk. The Aggressor, however, had sufficient remaining strength to inflict some damage to U.S. Air Forces aircraft and installations. It was the view of the Air umpire staff that U.S. Air Forces had, at this stage of the maneuver, the power to practically ground Aggressor aircraft by raids on Aggressor's installations.

D-day - 2:

On April 26th, the United States Air Forces flew a total of 44 missions as apposed to Aggressor's 12 missions. A total of 200 sorties were flown this date by United States Air Forces, of which only approximately 70 sorties were against Aggressor air and air installations. This did not appear to be as great a number of air base strikes against the Aggressor as would have occured in actual warfare; however, the variance of missions undoubtedly gave personnel involved better training.

D-day - 1:

On April 27th, the United States Air Forces flew a total of 58 missions; and Aggressor Air Forces 13 missions. The U.S. Air Forces continued attacks on Aggressor air with a considerable percentage of his available forces used for interdiction tactics. The Aggressor Air Forces applied most of his available forces against United States air installations, which were a very lucrative target indeed, as the aircraft to take part in the airlift to follow were being marshalled at their bases.

D-day:

On April 28th United States Air Forces employed the bulk of their combat strength in support of the airlift of parachute and air-transported troops into the airhead. A total of 85 missions was flown by United States Air Forces as opposed by 16 missions flown by Aggressor. Aggressor continued to place most of his effort against the lucrative targets at Maxton and Greenville. Air Cover was flown for the troop-carrier formations, and air support was evident throughout the day. Close air support for the ground troops was called for and received by parachutists soon after their landings in the Mackall and Holland drop areas.

COMMENTS BY BRIG GEN J. HIGGINS, CHIEF UMPIRE - Cont'd:

At 0900 hours the 187th RCT air-dropped on DZ Luzon-Rhine, and by 1158 had secured the Mackall Airfield. The airfield became operational at 1300. At this hour the advance elements of the Carolina Base Section arrived, closely followed by the 511th RCT. Later in the evening the 504th RCT of the 82nd Airborne Division began to arrive, and continued until late evening.

At 1600 hours the 505th RCT air-dropped on DZ Holland, and attacked south and west to assist elements of the air-landed RCT's in exiting from the causeways crossing a similated swamp between the Camp Mackall-Fort Bragg reservations.

Two G-18 gliders, three assault-type transports, C-122, C-123, and C-125 and the giant transport C-124 arrived at the Mackall airfield during the day.

The mission of the 187th RCT was to secure the Mackall Airfield; subsequently to seize the west exits of the causeway and expedite the rapid crossing thereof by the 511th and 504th air-landed RCT's. The mission of the 505th RCT was to secure the eastern exits of these causeways, and to provide security for the debouching of the air-landed RCT's.

Artificialities dictated the time of arrival of the first transport at Mackall airfield, and no conclusions can be drawn from this particular action. However, it is the opinion of the Umpire Group that in planning future operations adequate time must be allowed for the capture of the field, for its immediate repair to the extent that it will support aircraft of the C-54 and C-74 type, and for adequate protection of the field against subsequent Aggressor retaliatory action. It should also seem advisable to stage in field operating personnel to insure that all installations are set up and the airhead fairly well organized prior to the arrival of a large number of transports bearing troops and equipment. The initial confusion in the airhead indicates that one individual must be designated as the airhead commander, empowered to render decisions on and command all personnel in the airhead. His functions should be similar to that of the beachmaster in an amphibious operation. Troops delivered, 6657, vehicles and major weapons, 265, Cargo, 1126 tons.

D plus 1:

On April 29th, the United States Air Forces were able to lift supplies into the airhead without serious opposition, and they could therefore devote considerable of their strength to attacking the battle area. On this date, however, the U.S. Air Forces suffered what was probably their greatest single loss during the maneuver, due to the attack by Aggressor on the marshalled aircraft at Maxton Airfield. Umpire scoring indicated a loss of 13 United States aircraft, on this date.

On the ground side elements of the 187th and 511th RCT made contact with the 505th RCT, clearing the causeways and preparing the way for the link-up of additional troops and supplies from the airhead at Mackall.

0489

COMMENTS BY BRIG GEN J. HIGGINS, CHIEF UMPIRE - Cont'd.

After relief of elements of the 505th RCT in the 11th Abn Div area, the two divisions attacked to the east in their zones of action. Heavy equipment and supplies continued to be flown in, and several service units arrived to strengthen the airhead. Troops delivered, 3678; vehicles and major weapons 811; cargo, 1890 tons.

The movement of troops on D plus one was noticeably slow, due to the long period that many had gone without sleep. Furthermore, there appeared to be a tendency to carry too much non-essential equipment, including heavy blanket rolls. Many vehicles, especially trailers, carried such items as tables, chairs, records chests, etc. which might well have been brought in at a later date. Every effort should be made to curtail non-essential empedimenta in the assault units; all available space should be taken up by additional rations, gasoline, and ammunition.

D plus 2:

Air action on this date was limited to a certain extent by bad weather, except for the airlift. Aggressor planes were unable to fly, but U.S. Forces fighters carried out a few missions.

At 0630 hours the 325th RCT air-dropped on DZ Sicily-South with the principal mission of securing the high ground to the SE of the DZ. After suffering an initial set-back by Aggressor tanks and infantry, they secured their objective in the vicinity of the intersection of Street and Long-street roads. Remaining elements of V Corps continued to press forward against Aggressor delaying tactics, and Pope Field was captured by the 504th RCT at 1545 hours. Troops delivered, 3478; vehicles and major weapons, 656; cargo, 1726 tons.

The air-drop had fighter protection during the flight in, but weather was marginal and a short time after the drop was completed closed in to the extent that close support for the ground troops was impossible. It was at this time that Aggressor launched a strong tank attack, with U.S. Forces severely handicapped by lack of planes in the air. Close support for U.S. Ground Forces by the U.S. Air Forces worked well on many occasions, and there were several instances where planes delivered requested fire within three minutes. However, there were also several instances where coordination was lacking, and close support could not be rendered. Further training on the part of both Air and Ground Forces is indicated to iron out still-existing difficulties. Further, continued thought must be given to methods of combatting tanks without the help of planes in situations of this nature--there will be times, because of adverse weather conditions, when overwhelming air superiority will be of limited assistance to ground forces. Initial results of close support by fast flying jets is very encouraging, and it is felt that such aircraft are CAPABLE of performing such missions well.

D plus 3:

Again, adverse weather conditions severely limited air action, and relatively few strikes were carried out by opposing forces. The airlift was interrupted for three hours by severe weather.

COMMENTS BY BRIG GEN J. HIGGINS, CHIEF UMPIRE - Cont'd

On the ground side all elements continued to press forward, and in the 82nd area began to dig in on a defensive position assigned by V Corps. Active patrolling was carried out and attacks by Aggressor Forces repulsed. Orders were received to launch a coordinated attack by both divisions on the morning of D plus 5 in order to seize Fayetteville Airport, (simulated).

D plus 4:

Adverse weather conditions continued to hamper air activities. United States Air Forces were very fortunate during the last three days of the maneuver in that the majority of missions scheduled by Aggressor were cancelled due to bad weather at Aggressor bases. From the Umpire standpoint, and I am sure also from the Maneuver Commander's standpoint, the bad weather was unfortunate, in that the degree of effectiveness of fighters against an airlift of this nature could not be accurately determined. It was only for a very brief period of time in the early morning of May 2 when an AD Navy night fighter engaged the air stream that the umpires were able to arrive at some conclusions. This particular night fighter, by authenticated reports, intercepted thirteen transport type aircraft. During the course of this action he was also credited with destroying a United States night fighter. The umpires, however, due to artificialities involved could not rule this number of aircraft destroyed, but it does point out possibilities which should be carefully studied.

Ground action on this date was limited to adjustments of defensive lines by the 82nd Airborne Division, and by seizing of the assigned jump-off positions by the 11th Airborne Division. Intermittent clear weather in the battle area permitted several ground support missions by U.S. Forces, and the majority were well executed.

D plus 5:

The airlift continued, building up supplies at both Mackall and Pope Airfields, many more service elements of the task force were brought into the airhead at this time. Troops delivered to the airhead on D plus 4 and on D plus 5 to conclusions of exercise at 1000 hours, troops, 4109; vehicles and major weapons, 916; cargo 5561 tons.

V Corps launched its three division attack (The Third Infantry Division was brought in for CPX participation during the last twenty-four hours) at 0800; the attack progressed well, units reaching their respective restraining lines in three to four hours, and the problem was terminated at 1000 hours.

SUMMARY

1. The Berlin Airlift type of logistical support for an airborne operation is feasible, with the limitations that a very high degree of air superiority be obtained and held, that the airhead be firmly secured and runways

0491

COMMENTS BY BRIG GEN J. HIGGINS, CHIEF UMPIRE - Cont'd.

be in shape to receive heavy transport planes, and that adequate time is allowed for the installation of control and operating personnel and equipment prior to the arrival of transport planes in large number and at short intervals. It is especially adaptable to the build up of type supply such as food, gasoline, and ammunition. Generally speaking, this type of supply accounts for 90% of the logistical support of combat action, once personnel, weapons, and transportation are in.

2. Airlift operations of the Berlin Airlift type must be made flexible enough to meet the threat of enemy action at the terminals and enroute. In the initial phases many interruptions can be expected, such as enemy ground raids, air raid alerts, etc. Enroute, unless provision is made for changes in routes periodically, mobile anti-aircraft artillery weapons will take an excessive toll. The effect of enemy night fighters on the air stream must be carefully evaluated.

3. The present commercial type transports, the C-54 and the C-74 have performed well, but lack of ability to transport bulky tactical equipment limits their efficient employment in the early stages of an airborne operation. The C-119, now replacing the C-82, has been warmly received by the ground combat troops, and can be said to have passed its first mass employment test with flying colors. There is a very definite need for assault type transports capable of landing on unprepared fields or roads close behind the assault troops.

4. It is believed that a much better estimate of the effect of "red alerts" would have been obtained had all troops played the problem seriously. Even if the commander is willing to accept risks in working his personnel when air attacks are imminent, due to the urgency of his mission, it is extremely doubtful that men will remain on the job under actual "red alert" conditions. This factor is also worth of careful evaluation in estimating the efficiency of operation of an airhead under constant air threat.

5. The umpire staff is of the opinion that actual dispersal of aircraft, to the degree permitted by the nature of the air bases and the number of aircraft involved, should have been played. Both the ceasing of work during "red alerts" and dispersal of the aircraft involve a time element which to a considerable degree affects the airlift mission.

6. U.S. Air Forces pilots were fooled on many occasions by the Aggressor air controllers and were directed to attack own friendly targets. It would appear that this was due to either poor intelligence information available to U.S. Air Foces, or to poor briefing of the pilots.

7. Many umpires and observers have remarked that quite a number of the personnel involved in this exercise did not appreciate the fire power of the modern fighter airplane. It is recommended that prior to engaging in a maneuver of this type that a demonstration of air power destructiveness be staged. Such a demonstration of the ground weapons of the airborne troops was presented on a small scale prior to this maneuver, and their effect demonstrated to all ground and air umpires.

THIS PAGE IS DECLASSIFIED IAW EO 13526

COMMENTS BY BRIG J. HIGGINS, CHIEF UMPIRE - Cont'd:

8. The mechanism of air umpiring is extremely complex. Simulated fire power, the necessary safety rules, and the artificialities injected into the problem made accurate damage assessment very difficult. We have much to learn in the business of air umpiring. It is strongly recommended that this problem be made a project to be pursued at a high level, possibly under the jurisdiction of the Air University.

9. Combat effectiveness on the part of the individual soldier can be considered excellent, but cannot be so considered insofar as our units are concerned. Our units are understrength, and until such time as the squads and platoons are brought up to full strength we cannot say that our units are "ready". However, it is believed that the framework of these units is sound, and filling the vacancies with well-trained basic soldiers would permit both airborne divisions to be in a satisfactory state of combat readiness within a relatively short time.

10. The success of the heavy equipment drops has been highly gratifying, and leads us to believe it may solve the present pressing problem of prividing long range anti-tank protection for the parachutist. Reconnaissance capabilities of parachutists are also tremendously increased.

11. The performance of the airhead logistical units, as organized by the Carolina Base Section, has been excellent, and it is believed that further tests will develop a special or airport unit organized to meet the unique requirements of an airborne operation.

GENERAL

In considering the simulated personnel casualties and materiel losses, it must be kept in mind that a very high percentage loss has been brought about by situations deliberately injected by the umpires. Aggressor has advantages that, aided by the umpires, permit him to anticipate and meet every U.S. Force thrust with ease, and to time his own attack when they would be most disastrous to U.S. Forces. It is my considered opinion that under actual battle conditions, with U.S. Forces intentions and dispositions normally hazy to the enemy, personnel casualties and materiel losses would not have been as heavy as our umpire records show. We have been purposely severe in assessing penalties in order to impress lessons on U.S. Forces. I am glad to say reports from the field indicate that this has not reduced aggresiveness one iota--rather, it has intended to make the airborne soldier even more determined to prove to aggressor that he learns quickly and only asks a chance to get another crack at him.

One of the outstanding features of the entire exercise was the spirit of cooperation displayed by all services, at all levels of command, and at all localities. It was especially gratifying to observe the speed with which representatives of the various services got together to work

0493

out problems which arose, and many difficulties were solved by on-the-spot agreements by the working personnel and promptly confirmed by the various headquarters concerned. There were, of course, many an argument and disagreements over minor points, but they were invariably brought about by honest differences of opinions; once settled, everyone cooperated. Also, and this statement appears again and again in my umpire reports, there was an obvious desire on the part of all participants in this exercise, from the recently-joined recruit to the senior commander, "to do a good job." By and large, there was a minimum of official buck-passing and of personal passiveness--the underlying spirit seemed to be an honest desire on the part of everyone to pitch in and work hard for a common cause. The unusual nature of this exercise may have been one of the principal reasons for this attitude, but regardless of motives this maneuver was certainly unique in this regard.

In my humble opinion, Exercise Swarmer has been highly successful. We have had many triumphs, and disappointments. We have learned a great deal, and we have obtained information on many points that may lead us to successful solutions of many problems confronting us. Above all, we have learned to work together for a common cause, and honest discussions of controversial points should enable us to provide for as many exigencies as possible, to the end that airborne operations of the future may be mounted with smoothness and dispatch, and minimum casualties.

CLOSING REMARKS

I would like to take this opportunity, at the close of my portion of the critique of Exercise Swarmer, to express my appreciation to the Maneuver Commander and his staff for the loyal support afforded the Umpire Group; to the Commanding General of Fort Bragg and his staff for their assistance in obtaining personnel and materiel necessary for our umpire set-up; to all tactical commanders, staff, and other personnel for the opportunity of working with you in the field and in garrison; to Aggressor, as represented by many units, for the fine spirit and splendid work in carrying out a most difficult assignment; and to my own very understanding and able staff and corps of umpires for their outstanding contributions toward making Exercise Swarmer a success.

COMMENTS BY MAJ GEN ROBERT M. LEE, COMMANDER, AGGRESSOR FORCES

The major elements of the aggressor force consisted of an aggressor headquarters with a commander, a chief of staff, and deputy chiefs for Army, Navy and Air Force who had a very few officer and enlisted helpers. Practically all chiefs and no Indians. This group with the able assistance of the Chief Umpire directed Aggressor operations.

The ground force was built around the 15th Infantry RCT (less the First Battalion), Third Infantry Division from Fort Benning, Georgia. Major attachments were:

The 41st Field Artillery Battalion
The 44th Heavy Tank Battalion and
The 70th Anti-aircraft Artillery Battalion.

The Air Units originally consisted of the 31st Fighter Wing with the following units attached for operations:

31st Fighter Bomber Group from Turner Field, Ga., and the 82nd Sq of the 78th Fighter Group from Hamilton Field, California, totaling 66 F-84 aircraft. Three days after the start of air operations this was reduced to 25 F-82's.

162nd Night Photo Squadron from Langley - 16 B-26 type bombers and photo aircraft.

A Navy Composite Squadron from VC-4 Squadron at Atlantic City, N. J., with 9 F-40's, 3 AD-2's and on P2V aircraft.

Air control, and coordination of Air and Ground Units was achieved by a Joint Operations Center and Tactical Air Control Center located at Aggressor Hq on the eastern edge of the Fort Bragg reservation, a Tactical Air Direction Center located at the Fayetteville, Grannis airport and two Tactical Air Control Parties disposed, as required by the air-ground plan, with the elements of the 15th Inf. This Tactical air control system was provided by the 606th Aircraft Control and Warning Squadron of the 502nd Tactical Control Group augmented by personnel from the Army, Air Force and Navy at large.

Briefly the mission of the AGGRESSOR force for this exercise was three fold -

1. To train and evaluate the training proficiency of, the units assigned by the maneuver commander.

2. In cooperation with the chief umpire, and as a training aid for the maneuver commander, to direct the action of the elements of the AGGRESSOR force in a manner to achieve the maximum training of the U. S.

THIS PAGE IS DECLASSIFIED IAW EO 13526

COMMENTS BY MAJ GEN ROBERT W. LEE, COMMANDER, AGGRESSOR FORCES - Cont'd:

Forces in the accomplishment of their mission.

3. To study and evaluate the most effective methods of counteracting an enemy airborne assault, enemy resupply and a continuing enemy airlift.

General speaking it is believed that to various degrees, the missions were accomplished. During the training phase of the maneuver, the air units flew 775 hours in preparation for air operations. Control elements were shaken down. The ground elements spent many battalion days digging up the Fort Bragg Game Preserve in preparation for a task which might logically be assigned to a force three times the size of the actual force. I might say this was accomplished without the loss of a single one of General Hodges turkeys or deer.

The operations during the tactical phase of the exercise were carried out according to plan with the exception of air missions after D-Day. From the 29th of April, D plus 1 thru the end of the exercise, Aggressor was able to get only 10 effective sorties into the maneuver area because of continuous bad weather conditions at the aggressor air bases, Langley and Norfolk Naval Air Station. The limited operations of Aggressor air on and after D-Day certainly underscored the requirement for almost complete mastery of the air in the area by a force establishing an airhead of this type. It is regretable from a standpoint of the lesson that might have been learned, that this condition was established by the weather, not in the airhead area but in the area from which aggressor aircraft were forced to operate.

In the ground action, significant aggressor successes were accomplished by coordinated groupings and short attacks or counter-attacks by the Infantry-tank-artillery team, then regroupings in preparation for sharp strikes against subsequent threats as they might occur. Mobility of all aggressor ground units, superior communications within those units and ration of 30 minutes sleep per man per day for seven days were the keynotes to the ability of the small aggressor ground force presenting any worthwhile opposition to the U.S. Forces.

Deception both in the air and on the ground played a significant part in aggressor operations. Until tanks were committed on D-Day, pneumatic dummies drew the bulk of U.S. air attacks on such targets. Skillful establishment of dummy artillery and anti-aircraft artillery positions and night displacements to previously prepared camouflaged positions prevented occupied positions from being discovered and effectively attacked by U.S. artillery and air until D plus 3.

On D plus 1 and D plus 2 when Aggressor Air was grounded because of

COMMENTS BY MAJ GEN ROBERT M. LEE, COMMANDER, AGRESSOR FORCES - Cont'd,

fog and rain at its bases, several U.S. air formations were taken under the control of an agressor forward ground controller. Attacks were directed against U.S. forces with pilots reporting good results, flight leaders were kept occupied attempting to get proper authentication for transmission until fuel was too low to remain in the area longer, and flights were diverted from their original missions.

In summary I feel that all aggressor units gave their best to provide the maximum possible training under the circumstances, for the U.S. Forces; received invaluable training themselves; and are leaving Exercise STA[illegible] with a feeling that during the past month, much has been accomplished.

COMMENTS BY BRIG GEN PAUL F. YOUNT, CAROLINA BASE SECTION

In presenting the logistics part of the critique, I am going to eliminate any comments that deal with single staff sections or technical services and discuss only lessons of general interest. There are seven points set forth on this chart which I believe are the major items of general interest that were high lighted during Exercise SWARMER.

NEEDS

1. Logistic planning to preced tactical planning.

2. Doctrine on Joint command at:

   a. Ports of Embarkation
   b. Ports of Debarkation

3. Doctrine on joint logistics in an airhead.

4. Establishment of Movements Control as J-6.

5. Joint military documentation for the Department of Defense.

6. Standardization of air transportability training in the Army and Air Force.

7. Independent communications for the logistical command.

The first item is one that I want to repeat even at the expense of being somewhat boresome as I have said it in every conference thus far - specifically "Logistics Planning to precede Tactical Planning". I believe the accuracy of that finding is now accepted. There have been many instances in which Tactical Planning in this Exercise has had to be revised due to the impossibility of providing proper logistical support to tactical operations. There probably is no place in which the necessity for close logistical support is more apparent than in connection with Airborne operations such as Exercise SWARMER. Actually, logistics planning should be concurrent and coordinate with the strategic planning preceding such an operation.

The second need demonstrated is for "Doctrine on joint command at: a. Ports of Embarkation, b. Ports of Debarkation." I have listed these two parts separately since in my judgment they are different problems. In both places it is essential that there be unity of command on a joint basis, if smooth functioning is to be assured. In the case of the Port of Embarkation I think further study is necessary before making specific recommendation as to the service exercising the joint command authority. However, that part of the command controlling the movement of Army personnel, equipment and supplies, and the loading,

COMMENTS BY BRIG GEN PAUL F. YOUNT, CAROLINA BASE SECTION - Cont'd:

lashing and documentation, should be an integrated unit under an Army commander reponisble to the joint commander. In the Ports of Debarkation, I believe that only one commander can be considered in the assault phase and that is the tactical commander of the Army. In the second phase after the airfield is secured and the build up has commenced there is still a predominance of Army interest whereas the Air Force role is that of a carrier and not that of a base operator. The personnel and cargo movements are almost entirely matters of Army interest. Therefore it is believed that the joint command should be vested in the Army throughout both the assault and the build up phases.

The third need is for "Doctrine on joint logistics in an airhead." Within the period covered by Exercise SWARMER there were no significant requirements for Air Force logistical support. However, with the build up of fighter strength such a need would develop. It is not believed that the services could afford the luxury of two independent logistics commands in the early phases. Therefore, it is believed that we should develop doctrine on joint logistics where common items are involved, not of course where air technical supply is involved.

The fourth need is the "Establishment of movements control as J-6," in accordance with current doctrine taught at the Armed Forces Staff College. Initially the movements program was to be prepared by means of a teleconference under the guidance of J-4. It became apparent prior to action that the movements control function in connection with an airborne or air supply operation had to be extremely flexible and a continuous in order to be responsive to tactical needs. Accordingly, a permanent committee called the SWARMER Airlift Planning Agency was established under the supervision of J-4. Thus, the committee did not have authority to take final action in the name of the Task Force Commander. In my opinion, it should have been organized as an independent joint staff function with its head (J-6) empowered to act for the Task Force Commander. I believe that the importance of movements control is so great due to the time factor in air operations, that this action is essential.

The fifth need is for standardization of "Joint military documentation for the Department of Defense." In Exercise SWARMER we found multiplicity of documentation due to variation in usage between the airborne elements of the Army and the Air Force. The Carolina Base Section adopted Air Force forms 95 and 96B as being the best available for our purposes. However, these forms are by no means ideal and it is recommended the whole matter of documentation be studied on the level of the Department of Defense in order that all services use common documentation.

The next need demonstrated was for "Standardization of air transportability training in the Army and Air Force." Wide discrepancies were developed between Army and Air Force doctrine and regulations. Existing Army training publications are at variance with Air Force regulations and should be revised. A specific recommendation in this connection is that the Air Materiel Command have authoritative representation at all air transportability schools so as to insure that joint doctrine is developed which recognizes the needs of tho Army and the essential safety requirements of the Air Force.

The seventh need is for "Independent communications for the logistical command." While the lack of such communications in Exercise SWARMER was the result of shortage of Signal Corps personnel to install and operate such communications, the impact of their absence was quite apparent. Proper logistics support and control of movement are impossible when the logistics commander is dependent upon an already overloaded tactical net for communications with the depots, airports and airheads.

As I have said, these are points of general interest only. Items of specific interest to various staff sections and technical services will be covered in the final report. However, I would like to stress the point, in connection with this critique, that the concept of air supply developed in connection with SWARMER is applicable not only in connection with parachuted assault operations such as characterized SWARMER, but is equally applicable to supply of an isolated element of a command, such as occurred with the 14th British Army in Burma.

During Exercise SWARMER, the 7th Transportation Medium Port, with minor augmentation of officers only, was used as the parent unit for Headquarters Carolina Base Section and the four ports. The strength of this organization is inadequate to support that number of headquarters during a war time operation. The unit served successfully in this Exercise since the period of operations was short and in addition many of the functions that would be exercised by a base section in time of war, especially the direction of Engineer and Signal Corps service functions, were missing. One solution to this would be the use of a Transportation Major Port (TO & E 55-110-1) with its greater strength and capabilities. Still another solution may be the use of the Logistics Command if the composition and utilization are developed along the present pattern of thinking. However, even though the Logistics Command is used to staff the Base Section, the Transportation Ports should be utilized to staff the operation of aerial ports of embarkation and debarkation.

As you know, the Carolina Base Section was formed late in the Exercise. As a result, all the initial planning was carried on by the staff of the V Corps, and their cooperation and support subsequent to the formation of the Carolina Base Section was most helpful and contributed much to the success of the Carolina Base Section.

COMMENTS BY BRIG GEN PAUL F. YOUNT, CAROLINA BASE SECTION - Cont'd:

The only unsatisfactory part of the entire maneuver is that I cannot honestly make a single derogatory remark about the Chief Ump or his subordinates.

THIS PAGE IS DECLASSIFIED IAW EO 13526

COMMENTS BY MAJ GEN P. W. CLARKSON, U.S.A.

Exercise SWARMER was essentially an airborne operation, the principal objective being to seize and establish an airhead with airborne forces, and to establish a Berlin type airlift to supply the ground forces through the airhead. Therefore, my comments, with that in mind, are confined to matters relating to that objective. After all, the purely ground forces combat operations developed little that was new. It did provide valuable training for commanders and staffs, and troops. The ground exercise did much to provide training to overcome the very deficiencies that were disclosed.

For planning, time was too short. It seems it always is, both in maneuvers and in actual operations. We must expect to work under presure.

In preparation for an airborne operation, for best results, a few of all types of aircraft to be used, should be provided in advance for training of troops who are to load and unload these craft.

Bulk supplies must be made more realistic. It was too easy in this operation to divert airplanes hauling simulated supplies to handle actual supplies which were behind schedule. All simulated supplies should be represented by sacks or boxes of sand of proper weight.

Port of debarkation units organized like the Shore Party in an amphibious operation should be developed. The Engineer Special Brigade, Boat and Shore Regiment (less boat elements) could well be used for this purpose. It should bring in an advance party with assault troops and the remainder in the first planes to land.

Forward Air Controllers worked well in the operation and did direct air strikes in support of front line troops. For best results, FAC's and TACP's should be assigned to duty with assault troops 3 to 4 weeks prior to D-Day.

In this exercise, as in all exercises in which I have been involved, many communication difficulties were encountered. Most of these are not equipment deficiencies, nor lack of maintenance personnel and maintenance equipment, but are due primarily to lack of trained operators and users - mostly the users. Air and wire circuits are cluttered with too much unimportant traffic.

There was too much waiting around at embarkation ports by troop units after receiving port calls. One unit was called to the embarkation port and waited over 15 hours before embarking aboard planes. It was, of course, one of the purposes of this exercise to determine the causes of such delays and to develop a system which will avoid them.

Publications are available which set forth the capacities and

COMMENTS BY MAJ GEN P. W. CLARKSON, U.S.A. - Cont'd:

capabilities of the various aircraft. In many cases it was only after a great volume of work had been done in planning that new actual or maneuver capabilities were determined. Aircraft capabilities as listed in Air Transportability publications should be revised and kept up-to-date. These publications should also set forth peace-time or maneuver special limitations on allowable lift of each craft. It is essential that platform scales be provided at ports of embarkation to weigh vehicles as they come in and, whether or not the load is suitable, should not be left to the determination of the individual pilot. An Air Force Port Inspector, or similar official, should make this determination.

Tactical air support was available in quantities far in excess of what a Corps could expect. The air-ground liaison worked through forward air-controllers and front line troop units were loud in their praise of the prompt, heavy support provided throughout the problem. I would recommend a training exercise using live ammunition, stationary and moving targets representing tanks and other likely weapons, with Forward Air Controllers, TACP's and Infantry company and battalion commanders present. Let's satisfy ourselves on the one point not demonstrated in this exercise, but that we believe can be done - that support aircraft, on call from FAC's, can locate exactly, hit, and destroy what the front line commander wants knocked out.

I should like to say in conclusion that this has been a most valuable training exercise to all who participated; it has developed much factual information in regard to an airborne, air-supplied operation, and it has brought the Air Force and the Army close together in appreciation of each other's problems and respect for each other's ability to do their job.

THIS PAGE IS DECLASSIFIED IAW EO 13526

REMARKS OF GEN W. R. WOLFINBARGER

I will open my remarks by complimenting the men of the Army, Navy, Marine Corps, and Air Force with whom I have worked, who by their enthusiasm and inter-force co-operation have made exercise SWARMER possible.

First - in my opinion the command organization, set up for SWARMER, was sound from every aspect. When lines of command and responsibility are as simply and clearly drawn as they were in this case, the tasks of subordinate units and their commanders are made immeasurably easier. The importance of this feature in a joint manouver cannot be over emphasized.

From the Air Task Force point of view, the high-light of the Exercise was the integration of Troop Carrier and Strategic Air Transport elements into a single Air Transport Force. It demonstrated to my complete satisfaction that Troop Carrier and Air Transport concepts are capable of successful combination and that the two elements, when jointly employed, logically and successfully complement each other in this type of an operation.

The Exercise has clearly shown that each force has a great deal to learn from the other and a simple, down-to-earth example will illustrate my point. A Troop Carrier precept is that a crew member is responsible for the loading of each plane. This is an excellent doctrine, to be sure, in a short operation involving only a few missions. But, on the other hand, the Strategic Air Lift people learned long ago that it isn't the answer for a sustained operation. Crew members must have their sleep, just the same as other people, and it is far more efficient to have a trained technician take over supervision and insure correct weight distribution in the aircraft. But the air lift people also learned that this job specialization does not lessen the necessity for multiple crews to get the highest possible utilization rate from asagined aircraft - and a high utilization rate is an absolute "MUST" for efficient operations of this type.

Our principal difficulties from the Air Transport point of view were attributable to some extent to the fact that the concept of the plan was changed to include a Strategic Air Lift after much of the basic planning had been completed. The commitment of MATS at a late date in the planning phase required last minute adjustments in earlier plans and entailed air movement of both Army and Air Force units and equipment from one base to another during the time that should have been utilized in firming up the details of the joint operation and indoctrination in Air Transport and Troop Carrier concepts.

Joint planning by all participating forces from the very inception of the plan is a prerequisite to the attainment of a degree of inter-service indoctrination that will allow clear-cut delineation of the responsibilities of each force and prevent misunderstanding after the operation begins.

0504

REMARKS OF GEN W. R. WOLFINBARGER - Cont'd:

Internally, the Air Transport Force ascribes some of its difficulties both to the inadequacy and lack of T O & E's. Troop Carrier T O & E's need revision for sustained operations. Traffic personnel, mechanics and flight crews must be added to a chieve greater efficiency in the use of their airplanes. And, if MATS is to engage in combat operations, it should have a T O & E. Further, it might be well to consider official recognition of this type of operation for MATS and include it in its mission and training curriculm.

On the Tactical Air side of the operation I would like to say that it was a gratifying experience to have sufficient aircraft available. All of you know that too often this ins't the case. But I can state that during Exercise SWARMER, with the exception of the times when we were grounded for weather, it was seldom that a request for tactical support of cover would not be fully met.

We consider the innovation of a full scale use of fighter pilots as Paratrooper - Forward Air Controllers to have been highly successful. In cases these "Air Force Infantryman" were calling down support aircraft less than ten minutes after they had jumped with the airborne battalions.

From the deficiency aspect, the Exercise has shown that we need airborne early warning radar for this type of operation, Completely successful air defense of an airhead or cover for transport aircraft cannot be attained with the present high speeds of fighter aircraft when the early warning radar is sited a hundred or more miles to the rear.

Finally, I believe there is much to be done in the establishment of air umpire techniques for future exercises. For one thing, we must have quicker and more accurate results of the days's sorties in order that we may pattern the next day's strikes on the previous day's operation.

Another consideration should be dependable utilization of umpire channels for relaying all changes in the play of the Exercise. I suspect you know that I am referring to the case of the artillery battery at Fort Bragg. It's a bit demralizing to find out at 2100 hours that 37 of your aircraft are blazing on the ground at Camp Mackall from artillery fire that started five hours earlier. Simulations are hard things to counteract if they are kept secret. We think we could have silenced that battery or at least dispersed our planes on the ground if we had just known we were being fired at - or for that matter, maybe we could have simulated knocking it out.

0505

COMMENTS BY LT GEN JOHN R. HODGE, TASK FORCE COMMANDER

Gentlemen: There was one characteristic of this maneuver which struck me as being entirely different from any maneuver I have ever seen. That was the prevailing spirit of brotherly love that existed throughout. Everywhere I went I found good relations between troops of Task Force SWARMER, the Umpires and Agressor. Included was a spirit of cooperative effort on the part of all, aimed at making the Exercise a success. I only hope that future exercises may carry the same spirit, since this is as it should be to get the best out of the hard work that goes into an exercise. This attitude was the result of several things. First, careful planning; second, careful and intelligent briefing of all hands; third, careful supervision of the Exercise, so that all phases were kept in balance; fourth, intelligent handling and use of Aggressor in its primary role as a training aid and not allowing the Exercise to get into an all out two-sided battle.

This maneuver was a bringing together, or a marriage, of several individual accomplishments that we knew we could do. Strategic airlift was operated in Berlin. We have demonstrated our ability to move equipment in troop carriers. We have demonstrated our ability to make mass tactical parachute jumps and drop certain heavy equipment from airplanes. We have demonstrated our ability to use tactical air in support of operations. We have demonstrated our ability to carry on ground operations after arrival in an airhead. Exercise SWARMER is the first time in a training exercise that we have joined together all these elements in one unified effort. There was no precedent for the planning of this type of maneuver. Naturally, there was considerable scrambling in the planning and setting up of some of the organizations to operate. Participation leaves no question but that operations into the airhead closely paralleled amphibious operations in many respects, and in some things we can use amphibious experience to a good purpose.

All of us must study continously the conduct of operations of this type. The full lessons of this maneuver cannot be covered in this critique, since the results of the Exercise must be carefully studied and analyzed and fully digested before we can reap the full benefits. We should have additional exercises of this type and should extend them to include operations over water, combined with amphibious operations and sea transportation as an integral part.

In our joining up of our known capabilities to make up this Exercise, we found several rough joints. We found some deficiencies in our organization and in our training to get the smoothest operation. For example, our troops of the Army have not had adequate training in air transportability - in actually using airplanes. Our use of air transport for equipment, supplies and personnel was in a great degree on-the-job training in this Exercise. Those who participated in it, I would say, are now proficient. We lacked proper organization for handling of

COMMENTS BY LT GEN JOHN R. HODGE, TASK FORCE COMMANDER - Cont'd:

supplies and equipment at the base and after arrival in the airhead. I think a study of what we used and results attained will give us a much better picture of our needs in this line and something to tie to in future planning. One definite must is an organization for early use in the airhead for handling of incoming planes with equipment and supplies. In my opinion, this should be similar to the Navy "Beachmaster" set-up. We must be trained to make more effective use of available air transport under tactical conditions. In other words, we must learn to marry up loads with organizations, so that we do not have any planes running partially empty. In this Exercise, we were unable to utilize anything like full plane capacity, due, in a great degree, to lack of experience in load dispatching. Under the best of conditions there will be some loss of efficiency where tactical considerations and combat loads govern, but we must make every effort to reduce that loss to the minimum. I am convinced that we can raise transportation efficiency under tactical conditions to as high as 80 to 85 percent of the plane capacity.

Before we become too enthusiastic about air-transportability as the final word in conduct of operations, I would like to point out that in this type of operation, with present equipment, we will be without tanks and without the heavy Engineer equipment that is so essential in repair of airfields and bridge operations. One other deficiency of the Army is the lack of a sure tank killer. It is my opinion that the proper use of tactical air support with the 5 inch rockets on the fighter-bomber can do a lot to overcome this deficiency. This means, however, is not effective during periods of bad weather and darkness. We must push a light mobile and effective anti-tank weapon which can be dropped from the air and give more thought to fully air transportable equipment of all types.

One of the outstanding features of the tactical air support was the splendid work done by the forward air controllers. I want to praise particulary those fighter-bomber pilots who volunteered to go to jump school and who jumped with the troops, carrying radios with which they contacted and controlled the airplanes in the forward areas. They did outstanding work. This, combined with the enthusiastic efforts of the pilots in the air, went a long way to establish the confidence of the ground soldier in his flying brother to give him the assistance that he needed. We must further develop and build up this confidence and teamwork.

In closing, I want to emphasize what to me was after all the outstanding thing about the entire Exercise. This was the high cooperative attitude and teamwork effort of everyone concerned. The ingenuity displayed throughout to overcome difficulties and the intelligent interest of every officer and man in the command was outstanding. Gentlemen, it is up to everyone of us here to be constantly on guard that we may be as good as those whom we command.

SUMMARY OF REMARKS OF LT GEN LAURIS NORSTAD

From the first date we started this maneuver, I have been impressed with the excellence of the maneuver staff. In preparation for this critique, I had members of the staff prepare 15 or 20 pages of notes. However, it appears these notes will not be needed inasmuch as most of the comments which were prepared have already been touched upon by the experts here.

As a preliminary remark I would like to emphasize what has already been stated during the critique this morning. An actual operation of the kind we have just run simply cannot be conducted unless we have clear air superiority. With this in mind, we entered this exercise with a high degree of assumed air superiority. In an actual operation I feel that an early movement of 12 or 16 fighter aircraft into the airhead at the time that the airhead is established will be absolutely essential in order to preserve the air superiority we will require.

My main comment is one that has not yet been touched on at length. It concerns the question of organization for a real emergency. We should be prepared to conduct an operation at least somewhat similar to the one we have just run. At the present time, one of our greatest deficiencies is the fact that a task force of this type does not actually exist in the field. I feel that elements of such a task force should be brought together. Accordingly, I intend to recommend to the Chief of Staff, U.S. Army, that, in my judgement, V Corps should actually be constituted as a tactical organization; that is, it should have under it the Army units that will make up a tactical corps in case of an emergency. I will recommend specifically that the 11th and 82nd Airborne Divisions, at least, be tactical units under V Corps. It would be a great advantage in having the 11th located geographically near the 82nd Division. However, for administrative reasons it might be necessary for it to remain where it is. I do not limit this concept to the 11th Division. Perhaps the 3rd Division should also be part of this corps.

The same principle holds on the air side. General Wolfinbarger's organization (TAF) must be built up. It is essential for it to be together under his control and in a position to balance the ground component of the task force. I intend to recommend to the Chief of Staff of the Air Force that this be accomplished. It would be of no value to organize one side of the task force without organizing the other. If the Army organized a tactical corps, it should be balanced by a tactical Air Force organization and vice-versa.

The second main point I have is on the air side and concerns the use of air transports in this type of operation. There remains a question of the efficiency of air transports in the operation of a strategic airlift. I am informed that we operated the airplanes we had at about 60 percent efficiency. Regardless of whether air transport operates at maximum efficiency or at 5 percent efficiency, its job in this type of operation is to meet the requirements of the ground organizations it is supporting.

SUMMARY OF REMARKS OF LT GEN LAURIS NORSTAD - Cont'd:

Within the air organization, I think that with a better utilization of air transport the number of sorties flown could be increased. Efficiency of operation from the air standpoint alone might be raised 10 or 15 percent. By analyzing and applying the lessons we have learned in this operation, we should be able to solve, at the beginning instead of the end of the operation, the problem of the most effective allocation. This would raise the efficiency of the operation as a whole and make more loads available. In this respect, there is at least the basis for suspicion that the tactics and technique are developments for the use of horse-drawn vehicles, early motor vehicles, and the train and the ship. I would like to see someone on the Army side analyze the airborne operations to see if it is possible to modify tactics to get more out of available aircraft. We are derelict in our duty if we do not analyze and endeavor to improve our efficiency. There will always be a shortage of transport type aircraft. Accordingly, we have to increase the efficiency of air transport and get more out of aircraft flown. I would suggest to the 82nd Division, V Corps, and the Airborne Training Center, that the tactics and timing of this type operation be carefully analyzed to see if we can increase efficiency 15 or 20 percent. Such an increase in efficiency would add the equivalent of another group to the operation. I do not believe we can carry out an expansion of our air transport force until we are sure we have done everything we can to maximize the utilization of what we already have.

This maneuver has pointed up, in the judgement of those most closely associated with it, the direction of future exercises. There is now under consideration the question of exercises with armored forces. One such exercise would involve the support of an armored force on the move. I hope this exercise will be approved. Another exercise which is indicated by the one we have just held would be one operated jointly with amphibious forces. It would be, in fact, a combination of an operation similar to Swarmer with an amphibious operation.

If major mistakes have been made in this maneuver, I am afraid I must claim a large share of the credit. To me, such mistakes are understandable since they were to some degree expected. I hope, however, that you people have found this exercise useful and profitable. We have learned, and will carry back to our particular fields of interest and activity, many useful lessons. I hope we will be able to apply them. I hope also that the lessons are not as bad as indicated by one of our national periodicals. One of the weekly magazines has stated that I am a member of the Ming Dynasty. That would indicate that I was a Chinaman. The only basis for this statement is that this exercise has been upside down and backwards. I hope you people haven't found it quite that bad.

Thank you for the enthusiasm with which you have entered into this problem. The most inspiring thing to me has been getting out to the field and seeing the men at work. They couldn't have worked harder if it had been actual combat. This springs from good leadership and the concentration of attention to the problem. When we study the lessons of this exercise you will find the reward for the enthusiasm you devoted to this maneuver.

Thank you all for the remarkable performance you have turned in.

END

1. GENERAL

a. One of the paramount objectives of Exercise SWARMER was a check to determine the adequacy of existing doctrine and procedures for the coordination of air and ground operations in the establishment and expansion of an airhead deep in enemy territory. Letter, Office, Chief Army Field Forces, Subject: "Testing of Joint Doctrine", 21 March 1950, directed that Commanding General V Corps, in conjunction with Headquarters Tactical Air Force (Provisional), test proposed chapters of the Joint Training Directive. Pertinent chapters were: "Joint Operations Center", "The Air-Ground Operations System", "Air Liaison Officers", "The Tactical Air Control System", and "Offensive Air Support of Airborne Operations".

b. The principle requirements generated by the cited directive were:

(1) Procurement, assembly and instruction of Army personnel for manning the Joint Operations Center and for employment as Ground Liaison Officers.

(2) Development of plans and procedures for receiving, processing and coordinating requests for air support; this included plans for support in early phases, prior to establishment of ground point to point communications within Divisions and between Divisions and the Joint Operations Center.

(3) Coordination of plans for air support with Corps, Divisions and supporting elements of the Air Force and Navy.

(4) Operation of a complete Air-Ground Operations System to implement the plans.

c. Army elements consisted of one (1) Corps controlling two (2) Airborne Divisions and one (1) Infantry Division. The Infantry Division was to have participated on a CPX basis; however, it did not actually enter the problem insofar as air support is concerned. Air Force elements consisted of Tactical Air Force (Provisional), operating the equivalent of nine (9) fighter-bomber squadrons (including Navy Air units and Air National Guard Units), one (1) Tactical Reconnaissance Squadron, three (3) Interceptor Squadrons and two (2) Light Bomber Squadrons. The Joint Operations Center functioned between V Corps and Tactical Air Force (Provisional).

d. Details of operations maybe found in the report of V Corps and in that of Air Task Force (SWARMER) of which Tactical Air Force (~~XXXXXXXXXXX~~ SWARMER) was a component.

2. SUMMARY OF EVENTS

a. The Air-Ground Operations Section submitted its estimate of personnel augmentation requirements for SWARMER to appropriate staff sections of Headquarters V Corps on 13 February 1950. These requirements were periodically reemphasized.

b. An AGOS officer participated in briefing and demonstrations covering general air-ground operations at the 11th Airborne Division, Camp Campbell, Kentucky during 21-25 March 1950.

c. On 23 March 1950, AGOS received four (4) of the five (5) proposed chapters of the Joint Training Directive mentioned in paragraph 1a above. Since planning for SWARMER had then been in progress for some little time, and since the ~~XXXXXX~~ provisions of the proposed chapters were to be implemented by 15 April 1950, the

0511

THIS PAGE IS DECLASSIFIED IAW EO 13526

arrival of the proposed chapters at the relatively late date mitigated against their thorough assimilation and implementation by all agencies concerned.

d. All AGOS personnel then available for duty attended a preliminary briefing on SWARMER air operations, conducted by Tactical Air Force (Provisional) on 27 March 1950. An AGOS officer participated, presenting the enemy ground situation and friendly proposed plan for operations.

e. On 29 March 1950, G-3 V Corps directed that AGOS prepare an Air Support Annex to the Corps Operations Plan for SWARMER. AGOS prepared and coordinated the Air Support Plan, which became Annex 9 to Operations Plan Number 1, V Corps.

f. AGOS initiated, coordinated and participated in a briefing on air-ground operations conducted for SWARMER ground umpires on 6 April 1950. The presentation consisted of illustrated lectures covering all aspects of air support, starting with the initiation of a request at Battalion level, its processing through the Air-Ground Operations System, its coordination within the Joint Operations Center and including the control measures employed in directing aircraft to the target.

g. An intensive training program for augmentation personnel was initiated 29 March 1950. Typical subjects presented were:

Concept of and Operational Plans for SWARMER

Organization of U. S. Army

Organization of U. S. Air Force

Air-Ground Operations System

Air Force Combat Operations

Tactical Air Control System

Air Force Communications System

Air-Ground Liaison Signal System

Radio-Telephone Procedure

Duties of Liaison Officers

Instruction was prepared and conducted by augmentation officers, by permanent AGOS Officers, by Air Force Combat Operations Officers and by Officer specialists in appropriate fields. Instruction culminated in a one day CPX in which requests for air support were processed and recorded. Other concurrent commitments of permanent AGOS personnel, such as preparation of the Corps Air Support Plan, the short preparation period resulting from participation in Operation PORTREX, and the piecemeal arrival of augmentation personnel, were factors handicapping the conduct of the most effective instruction.

h. AGOS and CCS Officers presented a two hour briefing and conference on details of SWARMER air support plans for the 82nd Airborne Division on 12 April 1950 and for the 11th Airborne Division on 14 April 1950. Attendance included Commanders and Staff Officers of Divisions and of subordinate units including battalions and separate companies. Similar briefings for Air Force and Navy units concerned with Air Support were presented at a later date. A team consisting of an Air Force Officer, an Army Officer and a Marine Officer visited Oceana NAS, Shaw AFB, Congaree and Morris Fields and Langley AFB to orient all air units on details of the air support plan and on the army requirements for air support.

i. Ground Liaison Officers and their signal teams moved to their stations during period 13-15 April 1950. After

THIS PAGE IS DECLASSIFIED IAW EO 13526

orientation, they moved rapidly into their operational duties.

j. Elements of the air-ground operations section moved to the maneuver area on 14 April 1950. The G-2 Air Section became operational at 0600 hours 15 April 1950. G-3 Air Section continued on a training basis until 18 April at which time, processing of pre-assault counter air and deep interdiction strike missions was inaugurated. AGOS integrated the Corps Commander's desires in JOC planning for these operations.

k. V Corps, Tactical Air Force, 82nd Airborne Division and JOC, on 24 April 1950, conducted a CPX in three phases. In the first phase, air alert aircraft received requests from battalion Forward Air Controllers, simulating initial operations prior to establishment of ground point to point communications within the regiment. The second phase covered operations of air alert aircraft directed to Forward Air Controllers by Division Air Liaison Officers. The third phase brought JOC into play, processing requests received from the 82nd Division over facilities of the 20th Signal Company, Air-Ground Liaison. A time study, based on ten (10) mission requests reveals the following:

Average time to process request through Air-Ground Operations Section -4 Minutes.

Average time to process request through Combat Operations Section - 7.7 Minutes.

Average elapsed time between receipt of request and planes over target - 73.6 Minutes.

Maneuver restriction on fighter aircraft denied their use in the area occupied by the 11th Airborne Division. This unit employed liaison aircraft in lieu of fighter-bombers to accomplish the first two phases of the CPX.

l. AGOS assisted in the pre-operational phase training of Air Force units by selection of locations within the maneuver area to be struck as simulated targets. Requests for strikes were processed through the Joint Operations Center as a further training device.

m. Throughout the entire planning phase, the utmost coordination was effected with Tactical Air Force. This included joint conferences, orientations and detailed planing on such varied matters as training and placing of forward air controllers, preparation and distribution of Target Area Designator grid overprinted maps, and employment of Anti-Aircraft Artillery. In many cases, AGOS participation consisted simply in establishing contact between appropriate planners. In other cases AGOS participated actively in planning.

n. Operational phase.

(1) For operations, observations and recommendations peculiar to the G-2 Air sub-section, see inclosure 1 appended hereto.

(2) AGOS, concurrently with CCS, commenced full operations, on 21 April (D-7) (G-2 Air had been operating since 15 April). The G-3 Air sub-section operated in three (3) shifts as follows:

1st Shift 0500-1300

1 G-3 Air Action Officer

1 G-3 Air Duty Officer

THIS PAGE IS DECLASSIFIED IAW EO 13526

1 G-3 Air Records Officer

1 Operations NCO

1 Clerk - Typist

2nd Shift 1300-2100

Same as 1st Shift.

3rd Shift 2100-0500.

1 G-3 Air Action Officer

1 G-3 Air Duty - Records Officer

1 Operations NCO - Clerk - Typist.

Draftsmen on shifts were shared with G-2 Air.

This organization continued in effect throughout the operation, ending 3 may. Outgoing shifts remained on duty at the end of their tours sufficiently to orient the incoming shift. Overall supervision of all shifts was exercised by a senior G-3 Air Action Officer who was a member of the permanent AGOS establishment.

(3) For operations, observations and recommendations of Ground Liaison Officers, see inclosure 2, appended hereto.

(4) For operations, observations and recommendations of the Signal Air-Ground Liaison Company, see inclosure 3, appended hereto.

0516

THIS PAGE IS DECLASSIFIED IAW EO 13526

c. Operations:

(1) Reconnaissance: See Inclosure 1.

(2) Strike: During the period 21 April - 3 May the Joint Operations Center received 212 pre-planned and 15 immediate request missions. Of the total 227 requests received, 152 were completely processed and laid on by the Air Force. The requests not laid on are broken down as follows: 20 were cancelled due to weather; 7 were withdrawn by Commanding General V Corps; 12 were cancelled because they duplicated other requests; 2 were cancelled after visual reconnaissance revealed no target; 25 were disapproved by the G-3 Air Action Officer; and 9 were disapproved by the Combat Operations Officer. Disapprovals by the G-3 Air Action Officer were based on targets being non-lucrative for air or of such low priority that the mission could not be executed with available aircraft. Disapprovals by the Combat Operations Officer were based on non-availability of aircraft or on CAA

administrative regulations prohibiting execution of the mission, e.g., low level attacks in populated areas. Of a total 2408 sorties flown by tactical support aircraft, 602, or 25% were flown in close support operations and 723, or 30% were flown on interdiction missions.

p. Redeployment phase.

Exercise SWARMER terminated at 1000 hours 3 May 1950. AGOS assisted in dismantling the field installations of the Joint Operations Center and administrative adjuncts. Personnel returned to Fort Bragg, prepared reports and participated in post-operations critiques and conferences. By 13 May, augmentation personnel were relieved and the AGOS was again reduced to its permanent personnel.

3. DISCUSSION OF PROBLEMS.

a. Personnel.

(1) The Air-Ground Operations Section established and presented its requirements for augmentation personnel, officer and enlisted, for SWARMER, on 13 February 1950. Requests were based

on provision for two (2) complete shifts and one (1) reduced shift at the JOC and for Ground Ln. Off Teams. Further, in the interest of disseminating accepted doctrine and procedures throughout the army, AGOS recommended that officer personnel be provided from army wide sources and consist of individuals presently, or in the near future expected to be engaged in air-ground operations. It was requested that personnel report for duty three (3) weeks before the exercise to permit proper training and development of teamwork.

(2) Several officers and enlisted men, whom it was planned would occupy responsible positions in the Joint Operations Center, arrived only after the installation moved to the field. Late arrival precluded adequate organization and training. The operation suffered accordingly, it being impracticable to conduct adequate training for personnel hitherto totally unfamiliar with air-ground operations and simultaneously carry out the required operational functions. Such concurrent training might be feasible if extended over a prolonged period; the duration of Exercise SWARMER dictated that pre-operation instruction be employed to ensure operational efficiency.

THIS PAGE IS DECLASSIFIED IAW EO 13526

(3) In addition to precluding the effective development of closely knit team functioning, the late and piecemeal arrival of personnel resulted in possibly lasting misapprehensions on the part of personnel as to the manner in which a well regulated Joint Operations Center functions.

(4) It is felt that the interests of the army, both operationally and educationally would have been better served in SWARMER, had adequate personnel been available early enough to have permitted proper orientation and team organization.

(5) See inclosure 4 for list of personnel participating in the Air-Ground Operations System for Exercise SWARMER.

b. Authority for selecting of Ground Targets:

(1) Tactical Air Force (SWARMER) provided aircraft on an air alert status for the army divisions throughout the exercise (the continued air alert status was required because the air-ground communications system failed, thus precluding the forwarding of immediate support requests - see paragraph 3c). Late on D-Day afternoon, reconnaissance aircraft sighted and reported a small group of tanks at a point approximately ten (10) miles distant from the nearest U. S. Forces near Camp Mackall airfield. The U. S. Forces consisted of a parachuted regimental combat team without heavy fire support weapons.

0520

THIS PAGE IS DECLASSIFIED IAW EO 13526

Air alert aircraft over the U. S. regimental combat team provided the only immediately available heavy fire support. Due to a simulated swamp lying between the tanks and the U. S. Forces, tank movement was canalized; tanks could be kept under constant air surveillance. They constituted no immediate threat to U. S. Forces. Additional aircraft were due in the area within twenty (20) minutes.

(2) The G-3 Air Action Officer on shift, an armored officer, weighed the pertinent factors; realizing the possibility that other potential counter-attacking forces could well be concealed near the U. S. RCT, he recommended strongly that the air alert aircraft remain on their current mission, that the reconnaissance aircraft maintain surveillance over the enemy tanks and that the tanks be struck by the aircraft due to arrive in the area shortly thereafter.

(3) Commander, Tactical Air Force (SWAMP LR), despite the protests of the G-3 Air Action Officer, directed that the air alert aircraft be withdrawn from support of the U. S. RCT and strike the tanks. Fortunately, no counterattack developed in the area of the U. S. RCT; ironically, there is evidence that the tanks were rubber dummies.

(4) The basic principle at issue is whether air officers or army officers shall have the authority to determine the priority in which air effort is

to be applied in a ground support role. It is considered mandatory that the principle be determined which would establish the authority of the army commander to determine such priority, since his is the primary interest.

c. Communications.

(1) Details of signal operations will be found in inclosure 3.

(2) Further discussion on communication difficulties will be found in inclosure 1.

(3) (a) Typical of the delay encountered in transmission of important operational traffic over the facilities provided by the signal air-ground liaison company was the following message: "Chicken Road recommended as BSL for attack on three May one nine five zero". This message, classified secret, and given Operational priority precedence, was handed to the operator for the 82d Airborne Division at 1505 hours. It was received at JOC at 1753 hours, or two hours, forty eight minutes later.

(b) Eight (8) typical encoded messages, selected at random, averaging 239 words each, required an average time of seven hours fifty one minutes (7:51) between origin and readiness for delivery to addressee. Four (4) typical clear messages, selected at random, averaging 18 words each required an average time of forty

0522

five minutes (0:45) between origin and readiness for delivery to addressee. A time study based on these twelve (12) random messages will be found in inclosure 5.

(4) (a) Magpie (82d Airborne Division) and Sweepstake (11th Airborne Division), while located approximately fifteen (15) miles apart in the objective area could receive each other strongly and clearly, both on CW and on voice. Both could receive Elmer (JOC), located approximately thirty (30) miles away, strongly and clearly both on CW and on voice. Elmer (JOC) could receive both division stations only faintly on CW and scarcely at all on voice. Traffic between JOC and the divisions was virtually impossible. Nevertheless, Elmer's reception of GLO transmissions, both voice and CW, over distances varying between fifty (50) and four hundred (400) miles was excellent during most of the exercise.

(b) Communication failure between JOC and the divisions, rendered impossible the processing of immediate support requests. This, in turn, required that air effort be wastefully expended in maintaining an air alert status with aircraft immediately available to divisions through ground to air VHF communications. This status of aircraft on air alert was necessary throughout the exercise, simply because of inadequate communications insert.

(5) As indicated in inclosure 3, a total of 999 messages, with 91,967 groups (or word count) were transmitted and received over the facilities of the 20th Signal Air Ground Liaison Company at the JOC. Analysis reveals that this load could be reduced by careful screening of all messages; coding and decoding could thus be concurrently reduced. However, the rapidity of operations, with correlative limited permissable time for accomplishing such screening render meticulous screening somewhat impracticable. Further, with adequate equipment, the traffic could have been readily handled without delay.

THIS PAGE IS DECLASSIFIED IAW EO 13526

(5) A system requiring two hours and forty eight minutes to process a fourteen (14) word classified message from a division to JOC (paragraph 3c (3) (a)) and forty five (45) minutes to process and eighteen (18) word clear message (paragraph 3c (3) (b)), is totally inadequate to meet the requirements of an air-ground operations system for speedy, secure communications.

4. CONCLUSIONS

a. The preparation of V Corps Air Support Plan by the G-2/G-3 Air, JOC, violated doctrine as enunciated in the chapter "The Air Ground Operations System" to the proposed Joint Training Directive. This expedient, however, was necessary because requisite personnel for such preparation were not available elsewhere within the Corps headquarters. Thus, the best interests of the Corps were served by this use of JOC personnel.

b. The action of Commander, Tactical Air Force (SWARMER) in withdrawing air alert aircraft from support of troops at Camp Mackall in order to attack tanks beyond the simulated swamp is considered to have constituted a serious infringement on the prerogatives of the Corps commander, through his staff representatives, to determine priorities for support of ground troops. There is no evidence to indicate anything but the best of intentions on the part of the Air Force Commander in his action. His intense interest in his mission of supporting army troops was magnificent.

c. There were no other known violations of established doctrine in air-ground operations for Exercise SWARMER.

d. The requirements of an air-ground operations system for speedy, secure communications cannot be fulfilled by the signal air-ground liaison company as presently constituted and equipped.

0525

THIS PAGE IS DECLASSIFIED IAW EO 13526

5. RECOMMENDATIONS

a. That, for future exercises involving participation of the permanently constituted air-ground operations section of V Corps, arrangements be made for its timely and adequate augmentation as may be necessary to fulfil its mission. Officer augmentation should constitute those individuals, army wide, currently or imminently to be concerned with air-ground operations.

b. That the equipment of the air-ground communications system be immediately reviewed to the end that operational requirements for expeditious and secure transmission of battle information be provided.

6. REMARKS

The permanently constituted air-ground operations section is continuing, in conjunction with representatives of Tactical Air Force (Provisional), the study and compilation of operational procedures, equipment and physical arrangements of the Joint Operations Center.

THIS PAGE IS DECLASSIFIED IAW EO 13526

JOINT OPERATIONS CENTER
AIR-GROUND OPERATIONS SECTION
POST EXERCISE REPORT - EXERCISE SWARMER

10 May 1950

1. Statement of problem:

The G-3 Air Duty Officer is one of three Officers assigned to each shift of the G-3 Air section of AGOS as it operates in a Joint Operations Center.

Purpose of Problem:

To test whether or not this office as so conceived is adecuate to the need of the G-3 Air section and if not to establish thru additions, deletions, and consolodation, an operating procedure that will best meet the requirements for such a duty under any and all circumstances and conditions.

2. Summary of events:

a. Chronological order: Not applicable to this duty.

b. General Description of Routine duties:

The G-3 Air duty Officer receives all requests for Air support other than reconnaissance requests and after checking each request submit it to the G-3 Actions Officer. He keeps all interested organizations from Army Group and tactical Air Command down informed through their respective GLO's of the bombline and its changes. He sends each midnight a Summary of G-2 and G-3 reports to all GLO's. He maintains the friendly ground situation on the ground situation map and he plots and simbolizes each target on the map as soon as the mission has been laid on. He assists the Records Officer whenever possible.

c. Detailed description of unusual operations, problems or equipment:

This office had never operated before; therefore it is not possible to say which are usual or unusual operations or problems. (Annex "A" details a new seating arrangement for the G-3 Air section that in the

0527

THIS PAGE IS DECLASSIFIED IAW EO 13526

opinion of this observer would eliminate much uncalled for movement and confusion).

Communications completely failed. However the facilities as installed were ideal and if they had worked much that is now confused and not understood would no longer be a problem. The section was able to render assistance by the use of spot reconnaissance. These reports of enemy action were given direct to the Air Control Officer who was in direct communication with each plane aloft and he would direct the required aircraft to attack the target described in the spot report.

3. **Discussion:**

a. Opinion of reporter on facts:

The complete failure of communications precluded this office carrying out its primary mission - that of receiving strike requests and keeping the GLO's informed of the Army situation. However before the problem actually started (D-Day) communications did function and it was possible to detect errors in the seating arrangement of the section and a smooth, easy and quiet flow of information was impossible. (Annex "A" diagram explains this reporters solution to this problem).

b. Opinions of other observers on facts:

This reporter had no opportunity to interview observers regarding the operation of the AGOS.

c. Description of newly proposed improvements:

This reporter has no knowledge of any proposed improvements.

4. **Conclusions:**

a. Statement on adherence or non-adherence to accepted doctrine, procedures and techniques. Reason for non-adherence. Effect of non-adherence.

As stated above, this office had not been in operation before these manouvers and no accepted doctrines, procedures or techniques had been established. It is believed that the adoption of the recommendations of the 3 G-3 Air duty Officers submitting reports will be a basis for the establishment of procedures and techniques.

b. Statement as to whether or not problem served its purpose:

Problem did serve its purpose in that it provided a means to determine and to evaluate the misconceptions held prior to the beginning of the Exercise.

c. Statement as to whether or not full use was made of capabilities (Specific emphasis on AGOS capabilities) but including those of other elements of which reporter has accurate knowledge:

It is not felt that full use of the capabilities of the persons operating in the capacity of the G-3 Air duty Officer were made. Example: The duty Officer was not allowed to use plain common sense as regards mission requests. Two or more requests that obviously should be consolidated into one mission first had to be submitted, entered in the Journal and completely processed. They were later disapproved by the Combat Operations Officer as such and came back with the suggestion that they be consolidated into one mission. The reporter has no accurate knowledge of the capabilities of the other sections within AGOS or of other elements.

d. General conclusions:

It is felt that these in AGOS should have more information on the capabilities, functions, armor and ordnance of aircraft used by the Tactical Air Command. That all those within AGOS should be able to express an opinion to other army personnel on the proper type of aircraft to be used for a specific target.

5. Recommendations

a. Equipment:

It is recommended that the G-3 situation map be placed directly

THIS PAGE IS DECLASSIFIED IAW EO 13526

in front of the Duty Officer and that in addition to his regular telephone instruments he be given a headset that can be plugged in to any of the three circuits abailable. This will enable him to check the bomb safety line at the time a mission request is received. To plot targets as they come in and give him complete freedom of both hands.

b. Communications:

Circuits provided were ideal except they did not work. Alternate means of communications must be provided.

c. Coordination:

No recommendations.

d. Techniques and Procedures:

1. All units submitting mission requests be familiar with the operations of AGOS within JOC and if the requesting unit must have numbers for each request it is recommended that that number be assigned by the duty Officer.

2. That one copy of the submitted requests to retained by the duty Officer until the completed copy is returned by the Combat Operations O Officer. This will enable the duty Officer to check on the progress of requested missions.

e. Personnel and Administration:

Subordinates should take or be given instructions from one person only. This procedure will eliminate much of the confusion that was so much in evidence during this exercise.

F. Other:

No recommendation

JOSIPH G. SEARS
1st Lt. FA
G-3 Air Duty Officer

THIS PAGE IS DECLASSIFIED IAW EO 13526

ANNEX "A"

Top View

Actions Officer	
Duty Officer	Clerk
Records Officer	Clerk

Situation Map

Side View

G-3 Situation Map	
Open space for passing papers.	
Duty Officer	Records Officer

Mission request is received by duty officer, checked on map in front of him, request form accomplished, passed to clerk for entry in Journal and number, back to duty officer and then actions officer. If discussion is necessary between actions and duty officers it can be accomplished without either moving or undue noise. Actions officer hands or takes request to COS depending where the COS has his desk and when mission is completed the actions officer passes completed form to duty officer who in turn gives it to records officer.

The G-2 Air is as should be entirely out of this picture. It might be placed on line after the records officer of anywhere G-2 desires.

THIS PAGE IS DECLASSIFIED IAW EO 13526

JOINT OPERATIONS CENTER
AIR-GROUND OPERATIONS SECTION
POST EXERCISE REPORT - EXERCISE SWARMER

10 May 1950

1. Statement of problem:

The G-3 Air Duty Officer is one of three Officers assigned to each shift of the G-3 Air section of AGOS as it operates in a Joint Operations Center.

Purpose of Problem:

To test whether or not this office as so conceived is adequate to the need of the G-3 Air section and if not to establish thru additions, deletions, and consolodation, an operating procedure that will best meet the requirements for such a duty under any and all circumstances and conditions.

It is not felt that full use of the capabilities of the persons operating in the capacity of the G-3 Air duty Officer were made. Example: The duty Officer was not allowed to use plain common sense as regards mission requests. Two or more requests that obviously should be consolidated into one mission first had to be submitted, entered in the Journal and completely processed. They were later disapproved by the Combat Operations Officer as such and came back with the suggestion that they be consolidated into one mission. The reporter has no accurate knowledge of the capabilities of the other sections within AGOS or of other elements.

d. <u>General conclusions:</u>

It is felt that these in AGOS should have more information on the capabilities, functions, armor and ordnance of aircraft used by the Tactical Air Command. That all those within AGOS should be able to express an opinion to other army personnel on the proper type of aircraft to be used for a specific target.

5. <u>Recommendations</u>

a. Equipment:

It is recommended that the G-3 situation map be placed directly in front of the Duty Officer and that in addition to his regular telephone instruments he be given a headset that can be plugged in to any of the three circuits abailable. This will enable him to check the bomb safety line at the time a mission request is received. To plot targets as they come in and give him complete freedom of both hands.

b. Communications:

Circuits provided were ideal except they did not work. Alternate means of communications must be provided.

c. Coordination:

No recommendations.

d. Techniques and Procedures:

1. All units submitting mission requests be familiar with the operations of AGOS within JOC and if the requesting unit must have numbers for each request it is recommended that that number be assigned by the duty Officer.

2. That one copy of the submitted requests to retained by the duty Officer until the completed copy is returned by the Combat Operations O Officer. This will enable the duty Officer to check on the progress of requested missions.

e. Personnel and Administration:

Subordinates should take or be given instructions from one person only. This procedure will eliminate much of the confusion that was so much in evidence during this exercise.

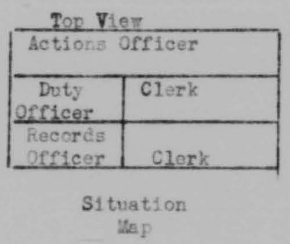
F. Other:

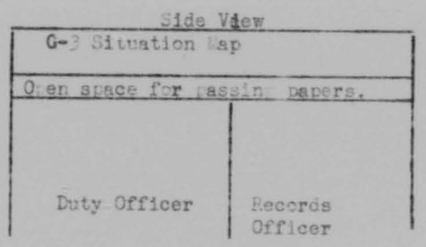
No recommendation

JOSIPH G. SEARS
1st Lt. FA
G-3 Air Duty Officer

THIS PAGE IS DECLASSIFIED IAW EO 13526

ANNEX "A"





Mission request is received by duty officer, checked on map in front of him, request form accomplished, passed to clerk for entry in Journal and number, back to duty officer and then actions officer. If discussion is necessary between actions and duty officers it can be accomplished without either moving or undue noise. Actions officer hands or takes request to COS depending where the COS has his desk and when mission is completed the actions officer passes completed form to duty officer who in turn gives it to records officer.

The G-2 Air is as should be entirely out of this picture. It might be placed on line after the records officer of anywhere G-2 desires.

THIS PAGE IS DECLASSIFIED IAW EO 13526

G-3 Air Duty Officer
Report on Exercise Swarmer

10 May 1950

1. Statement of Problem:

The G-3 Air Duty officer is one of three officers assigned to each shift of the G-3 Air Section of AGOS as it operates in a Joint Operations Center.

Purpose of Problem:

To test whether or not this office as so conceived is adequate to the need of the G-3 Air section and if not to establish thru additions, deletions, and consolidation an operating procedure that will best meet the requirements for such a duty under any and all circumstances and conditions.

2. Summary of events:

a. Chronological Order: Not Applicable to this duty

b. General description of Routine Duties:

The G-3 Air duty officer receives all requests for Air support other than reconnaissance requests and after checking each request submit it to the G-3 Operations officer. He keeps all interested organizations from Army Group and Tactical Air Command down informed through their respective GLO's of the bombline and its changes. He sends each midnight a summary of G-2 & G-3 reports to All GLO's. He maintains the friendly ground situation on the ground situation map and he plots and simbolizes each target on the map as soon as the mission has been laid on. He assists the Records Officer whenever possible.

c. Detailed description of unusual operations, problems or equipment:

This office had never operated before; therefore it is not possible to say which are usual or unusual operations or problems. (Annex "A" details a new seating arrangement for the G-3 Air section that in the opinion of this observer would eliminate much uncalled for movement and confusion).

Communications completely failed. However the facilities as installed were ideal and if they had worked much that is now confused and not understood would no longer be a problem. The section was able to render assistance by the use of spot reconnaissance reports sent in by pilots on routine photo reconnaisance. These reports of enemy action were given direct to the Air Control officer who was in direct communication with each plane aloft and he would direct the required aircraft to attack the target described in the spot report.

3. Discussion

a. Opinion of reporter on facts:

The complete failure of communications precluded this office carrying out its primary mission - that of receiving strike requests and keeping the GLO's informed of the Army situation. However before the problem actually started (D-Day) communications did function and it was possible to detect errors in the seating arrangement of the section and a smooth, easy and quiet flow of information was impossible. (Annex "A" diagram explains this reporters solution

0538

to this problem).

b. Opinions of other observers on facts:

This reporter had no opportunity to interview observers regarding the operation of the AGOS.

c. Description of newly proposed improvements:

This reporter has no knowledge of any proposed improvements.

4. Conclusions:

a. Statement on adherence or non adherence to accepted doctrine, procedures and techniques. Reason for non adherence. Effect of non-adherence.

As stated above, this office had not been in operation before these maneuvers and no accepted doctrines, procedures or techniques had been established. It is believed that the adoption of the recommendations of the 3 G-3 Air duty officers submitting reports will be a basis for the establishment of procedures and techniques.

b. Statement as to whether or not problem served its purpose:

Problem did serve its purpose in that it provided a means to determine and to evaluate the misconceptions held prior to the beginning of the Exercise.

c. Statement as to whether or not full use was made of capabilities (specific emphasis on AGOS capabilities) but including those of other elements of which reporter has accurate knowledge:

It is not felt that full use of the capabilities of the persons operating in the capacity of the G-3 Air duty officer were made. Example: The duty officer was not allowed to use plain common sense as regards mission requests. Two or more requests that obviously

THIS PAGE IS DECLASSIFIED IAW EO 13526

should be consolidated into one mission first had to be submitted, entered in the journal and completely processed. They were later disapproved by the Combat operations officer as such and came back with the suggestion that the be consolidated into one mission. The reporter has no accurate knowledge of the capabilities of the other sections within AGOS or of other elements.

d. General Conclusions

It is felt that those in AGOS should have more information on the capabilities, functions, Armor and ordnance of aircraft used by the Tactical Air Command; That all those within AGOS should be able to serve in a minor advisory capacity or at least be able to express an opinion to other army personnel on the proper type of aircraft to be used for a specific target.

5. Recommendations

a. Equipment:

It is recommended that the G-3 situation Map be placed directly in front of the Duty officer and that in addition to his regular telephone instruments he be given a head set ~~earphones~~ that can be plugged in to any of the Three circuits available. This will enable him to check The bomb safety line at the time a mission request is received, to plot targets as they come in and give him complete freedom of both hands

b. Communications:

Circuits provided were ideal except they did not work. Alternate means of communications must be provided.

c. Coordination:

No recommendations.

0540

THIS PAGE IS DECLASSIFIED IAW EO 13526

d. Techniques & Procedures

1. All Units submitting mission requests be familiar with the operation of AGOS within J.O.C. and if the requesting Unit must have numbers for each request it is recommended that that number be assigned by the duty officer.

2. That one copy of the submitted requests be retained by the duty officer until the completed copy is returned by the Combat Operations Officer. This will enable the duty officer to check on the progress of requested missions.

e. Personnel and Administration:

Subordinates should take or be given instructions from one person only. This procedure will eliminate much of the confusion that was so much in evidence during this exercise.

f. Other:

No recommendation

THIS PAGE IS DECLASSIFIED IAW EO 13526

FINAL REPORT OF GROUND UMPIRE

JOINT OPERATIONS CENTER, EXERCISE SWARMER

I. PROBLEM:

The Joint Operations Center was to accomplish unity between the Ground Troops and the Tactical Air Force in providing close support to the Ground troops; also assist in porviding aerial photographs of the terrain involved. Further mission was to evaluate the methods of close support and determine the requirements for supplying assault troops through and airhead established shortly after the assault.

II. SUMMARY OF EVENTS:

Joint Operations Center opened at Outer Camp Mackall on 14 Apr 50 with minimun confusion. However the actual operation did not begin until 17 Apr 50. At this time and through 22 Apr 50 the requests which were processed were of the aerial photo type. Most all these were flown by TAF. However most of the unit commanders were requesting the 1:4500 and 1:5000 basis. Due to the type A/C used, the timing and focal length of the camera it was impossible to obtain good photographs. So all of the missions laid on were on a 1:7000 basis and with excellent results.

During the week I acted as an observer, but on one day I acted as G-3 Air Actions Officer. This gave me an opportunity to observe the type requests the units were submitting. It was noted that some of the unit commanders were requesting the same photographic mission two days in a row. This would tax the availability of A/C and the production of the topographic company. It would not seem to be practical at this time as it is too far ahead of D-Day. However it would be sound policy when D-Day nears as the enemy situation would readily change and this would show up on the photographs.

THIS PAGE IS DECLASSIFIED IAW EO 13526

During the following week I had a chance to work in the capacity of G-3 Duty Officer. This gave me a chance to write the requests from the units and also had a better chance to evaluate the type request submitted. Most of the requests submitted were of enemy installations. However some of the requests were for pre-planned missions on transitory targets for the following day. This is not sound policy and they should have asked for On Call Missions. Normally a target of this type will not be in the same area two days in a row.

On D-Day I visited the initial drop on Rhine-Luzon DZ. The drop was to be made at 0630 hours but was cancelled until 0930 due to the A/C being weathered in. It was noted that a slight confusion existed in the reorganizing of the troops for the attack. In fact some units were not completely organized until about one hour after the drop. After the attack began I made a tour of the battalions and found that some of the FAC did not have contact with the A/C orbiting in the area. In one instance one battalion did not ever get his set into operation all during thier attack on Camp Mackall Air Field. This was a time that they needed it badly too. There was a radar station on the field which needed attacking before the troops could advance. On the other hand one battalion used the A/C to a good advantage in attacking a bridge which was held by the enemy. This bridge was important as it lead to the causeways. The A/C made at least three attacks on the bridge dispersing the enemy troops so that the US forces could advance.

D-Day afternoon I visited the drop of the 505 AIR on Holland DZ.

This drop was somewhat better organized than the initial drop due to the fact that the 505 had the support of the B-45 bomber and the F-84 fighters. In and during this drop the commanders made full use of the orbiting A/C and from information obtained from the recce A/C. One particular instance noted was that a truck column was coming up with troops to assist in repelling the airborne assault and an immeediate air strike was ordered on them.

On D+ 2 I again acted as G-3 Air Actions Officer and this gave me anotther opportunity to observe the type requests the units were sending in. In most cases the requests were of the armed recce type and only a few pre-planned missions. Most of the armed recce were aginst enemy troopsconcentrations and movemnets along the main supply routes. It was also noted that a few most requests were being sent in for pre-planning on transitory targets. At this time they should have asked for more ON CALL missions on these targets.

III. DISCUSSION:

One of the major problems of JOC was the manner in which the requests were received from the units. Most of this was due to the lines of communication which had partial failure. This solved sometime later when the lines cleared up.

Another major problem was the handling of Spot Reports from Recce A/C. In the earlier stages the G-3 Air Actions Officer did not have a chance to look at the reports and make a decision as to what should be done about the target reported. This was solved later by additional copies of the spot report being made and handled through the G-3 Air Action Officer. Then the units were notified as to the decision made and if an air strike was made or if it would be referred to tthe unit for laying artillery fire on it. In some

THIS PAGE IS DECLASSIFIED IAW EO 13526

cases the targets were behind the BSL and air strikes could not be laid on. The system of handling spot reports was devised by the Senior G-3 Air Actions Officer and the Senior Operations Officer.

Only one other major problem confronted JOC and that was the lines of communication to the GLO's and the units involved. It was very hard at times to get through to the proper persons and this was never solved completely.

IV. CONCLUSION:

On the whole JOC did accomplish its mission very well and found that high speed A/C could support ground troops closely. It was further found that it is possible to suppy and airborne assault in an air head close to the front lines, provided air superiorty could be maintained.

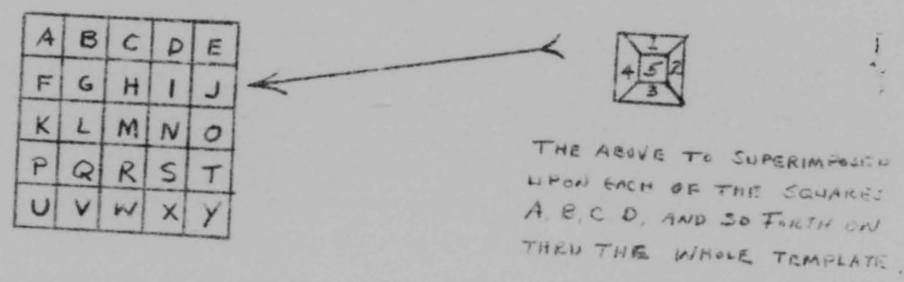
V. RECOMMENDATIONS:

It is recommended that the G-s Air Records Officer and the G-3 Duty Clerk on the third shift compile all the days reports and place them in the journal. The would give the G-3 Air Duty Officer and the G-3 Air Records Officer more time to spend in processing the requests from units and keeping them posted as to the disposition of each request and reasons if it were disapproved or if it were being laid on and at what time.

Further recommend that the attached diagram be adopted for future use in JOC. Sincerely believe that with this arrangement there would be less confusiOn in the center aisle and along the maps and boards on the wall. It will also tend to bring about closer coordination between the Ground and Air Force personnel.

Also recommend that JOC be made a definite part of all future operations.

Recommend that the following Target Area Designator System be considered for future uses. This would work very nicely on 1:25,000 map but could not be used very well on a 1:50,000 map.



Believe that the 62nd Topographic Company be given due credit for the fine and untiring work they did during the Exercise. They operated at full capcaity all time and never once did they say that they could not supply units with photographs requested.

0552

Inclosure 2 ~~TAB "~~ to ACOS REPORT for EXERCISE SWARMER.

COMPILATION OF REPORTS OF GROUND LIAISON OFFICERS

1. GENERAL

Experience of Ground Liaison Officers employed during Exercise SWARMER developed the following as broad general functions of a Ground Liaison Officer:

a. Advising Air Force Units regarding:

(1) Friendly and enemy front lines.

(2) Position and characteristics of Bomb Safety Lines

(3) Enemy gro nd situation and friendly ground operations.

(4) Target locations, characteristics and peculiarities.

b. Briefing pilots before each mission, interrogating them after each mission and passing to JOC any information of value so obtained.

c. Assisting Operations Officer in preparation of Flash reports.

d. Orienting Air Force personnel on Air Ground Operations and procedures for securing and coordinating close air support.

e. Maintaining appropriate situation and operations maps.

f. Supervising his Air Ground Liaison Signal Team.

g. Acting upon all requests and orders from JOC.

h. Doing anything within his capabilities which will result in the most effective close air support for the Army unit he represents. He is usually the only Army Officer on duty with his Air Force unit; he will be expected to answer a multitude of questions concerning the ground operation and should prepare himself accordingly.

Incl 2

0553

2. SUMMARY OF EVENTS

Various GLO's found that their activities differed in details, but the general pattern was as follows:

a. Reported to JOC for duty o/a 3 April 1950 and attended a course of instruction in air ground operations during period 5-14 April.

b. Reported to Air Force unit with which affiliated on 15 April; secured quarters and arranged messing for themselves and their signal teams.

c. Introduced themselves to the Air Force Commanders and Staffs; explained their mission.

d. Supervised arrangements for their signal teams; arranged for remoting radio-telephone into Air Force Operations room where indicated.

e. Conducted a course of instruction for Air Force personnel, covering generally:

(1) V Corps plan of operations.

(2) Background of AGGRESSOR and the enemy activities to date.

(3) Air Ground Operations System procedures; tracing a request for air support from the infantry battalion through all channels to the completion of the mission, including the reports rendered thereon; emphasis placed on procedures to be employed in the early phases of the Airborne operation.

(4) Duties and functions of Ground Liaison Officers.

(5) Organization of Army units participating in SWARMER.

f. Set up situation and operation maps.

THIS PAGE IS DECLASSIFIED IAW EO 13526

g. Briefed and interrogated pilots on missions; reported necessary information to JOC.

h. Rendered all possible assistance to affiliated unit; helped secure maps and helped to smooth out operational procedures by reporting difficulties to AGOS/JOC; was available for duty as necessary at all hours, day or night.

i. Upon notification, shortly after 1000 hours, 3 May, that Exercise SWARMER was concluded, GLO's reported their observations to Air Force unit commanders and returned to Fort Bragg; rendered final individual reports on their operations and were released.

3. DISCUSSION

Concensus of Ground Liaison Officers indicates that their greatest problems were:

a. Communications

(1) A common complaint was the prolonged delay experienced in receiving information; GLO's reported a time lag up to three (3) days for delivery of coded messages. This delay, coupled with garbled transmissions, rendered practically useless any JOC efforts to keep GLO's properly advised. Similar difficulties on clear messages atrophied exchange of battle information between GLO' and JOC.

b. Inadequate Prior Preparation.

(1) The majority of Officers detailed to augment the permanent AGOS had little or no background in liaison work in air-ground operations, or in Air Force functions. In general, the more promising officers were assigned to ground liaison duties. Effective instruction was hampered by late reporting of augmentation officers, by other commitments of permanent AGOS personnel, by the magnitude of the task and, additionally, for GLO's by a basic lack of available study material. GLO's were consequently prepared for their duties to a lesser

degree than was desirable. By assiduous individual application, they happily overcame this initial deficiency; however, air-ground operations will be better served in the future if GLO's can be more thoroughly oriented on their duties before reporting to their affiliated units.

c. Insufficient Personnel

(1) GLO's were on duty over protracted periods. Passage of information from JOC after the evening planning conference required that GLO's function late at night, assimilating and posting intelligence and operational information. Often, pre-dawn briefing of pilots was required. Operations throughout the day required GLO presence. A qualified operations non-commissioned officer to handle routine matters would have materally reduced the load on the GLO and rendered his operations more effective.

4. CONCLUSIONS

a. Ground Liaison Officers adhered to accepted doctrine in performance of their duties; they constituted an essential element in the successful operation of the air-ground system.

b. Communications provided by the Signal Air-Ground Liaison Company were inadequate because they failed to handle the required traffic expeditiously, accurately and without interruptions.

c. The pre-operation training program conducted by permanent AGOS officers was adequate, but a more through course of

0556

THIS PAGE IS DECLASSIFIED IAW EO 13526

instruction and the provision of more complete supply kits would have made Ground Liaison Officer operations easier and more effective.

5. RECOMMENDATIONS

a. That Ground Liaison Officers be provided with direct teletype communication (radio or land line) with JOC; that rapid encoding equipment, preferably integrated with teletype, be provided; that improved voice communication facilites be provided between GLO's and JOC; such voice facilities should permit rapid contact and break-in conversation.

b. That orientation and instructional material for Ground Liaison Officers be prepared and assembled; that Ground Liaison Officer kits, containing equipment and supplies peculiar to the needs of liaison teams be developed and made available to such teams in the future.

c. That Ground Liaison Officer teams be augmented by a minimum of one (1) Liaison non-commissioned officer SSN 2705 or equivalent.

THIS PAGE IS DECLASSIFIED IAW EO 13526

File

JOINT OPERATIONS CENTER
AIR-GROUND OPERATIONS SECTION
POST EXERCISE REPORT-EXERCISE SWARMER

1. STATEMENT AND PURPOSE OF PROBLEM:

G-3 Air Duty Officer on first shift from 0500 to 1300 daily. Charged with receiving and processing mission requests other than reconnaissance, from Corps and Divisions, keeping Ground Liaison Officers, Corps and Divisions informed as to location and changes of the bomb safty line and maintaining the friendly situation on the ground situation map.

2. SUMMARY OF EVENTS:

a. General description of routine operations.

Received all requests for air support other than reconnaissance. These requests were recorded on a special mimographed mission request form in four (4) copies. Upon reciept of a mission request, target was plotted on the ground situation map. The journal entry number of th t request was also recorded on the map. This t rget was then checked in its relation to the front lines and the bomb safty line. The mission request was then submitted to the G-3 Air Actions Officer's hands, the G-3 Air Duty Officer was free to return to his desk and recieve other missions. Kept all Ground Liaison Officers, V Corps, and Divisions informed as to the location of the bomb safty line and any changes that occurred in its loc tion.

Maintained the friendly situation on the ground situation map at all times.

In addition to the above, the G-3 Air Duty Officer and the G-3 Air Records Officer, coordinated their effort in keeping a day to day journal on all mission requests, messages, and other events.

b. Description of unusual operations, problems or equipment:

One of the main difficulties encountered was the failure of COS to promptly return a copy of the mission request to AGOS. Missions which were

THIS PAGE IS DECLASSIFIED IAW EO 13526

allotted to air alert aircraft sometimes were never returned until a search was made to locate them in order to close out the journal. It was observed that "On Call" mission requests were returned much faster than "Preplanned" mission requests. TACC was very slow in returning the circulating copy of the mission request which gave information as to the results of the mission. It was noted that there was improvement in this though, as the exercise progressed. Failure of COS to return our copy of the requests promptly, left our records incomplete. Because of this we were unable to keep requesting units posted on the status of their mission requests.

Another problem was having clerks assigned to a shift who were unable to type. Every clerk in the Joint Operations Center should be a typist due to the large volume of reports.

Lack of good, reliable communications hindered the performance of our mission. The basic plan of communications seems sound. That is having radio remoted to the G-3 Air Duty Officer with a Ground Liaison Officers net and a G-3 requests net. During the exercise these nets were always overloaded and most messages had to be sent C.W. with an operational priority. It seems that everyone was using an operational priority though because before the end of the exercise this priority did not mean much as far as getting a message through faster was concerned.

Several messages of an administrative nature were filed in the G-3 air journal. I believe that this should not be done as it tends to make the journal more a scrapbook of routine information than a journal of accurate operational data for which it is intended.

3. DISCUSSION:

a. Opinion on facts:

In my opinion, the physical layout of the Joint Operations Center, as operated during exercise swarmer, is not the correct answer. Due to the congestion

THIS PAGE IS DECLASSIFIED IAW EO 13526

of the Joint Operations Center, it should be set up to avoid as much movement as possible in each person's performance of his mission. As presently set up, the G-3 Air Duty Officer after receiving a mission request, has to move completely around the room to get to the ground situation map. If he has to make notes while at the map, he must use someone else's desk to do so. If the G-3 Air Actions Officer has some information for the Duty Officer, he either has to shout for him to come to his desk, shout the information to him, or get up and go to his desk. If the Actions Officer wants information from the journal, he has to go through one of the above processes with the G-3 Air Clerk. This happens frequently and thereby adds to the confusion within the Joint Operations Center.

b. Description of newly proposed improvements (Improvement #1) (See inclosure #1 for proposed lay-out of JOC).

If the lay-out of the Joint Operations Center was se

inclosed sketch, the G-3

Officer for him to be able to converse w

normal tone of voice thereby saving noise and movement within the Joint Operations Center. In this set-up the G-3 Air Actions Officer and the Senior Operations Officer could see the ground situation map without moving from their position. Upon receiving a mission request, the G-3 Air Duty Officer would only have to turn around, plot the trget, and hand it to the G-3 Air Actions Officer without moving from his general area.

One argument which has been raised against this proposal is this: Th t the Ground Officer and his counter part in the Air Force should sit side by side. During Exercise Swarmer there was no indication that they should be seated in that manner. Since the G-3 Air Acti ns Officer submitted all requests to the C.O.S., the Ground, and Air Duty Officers had no occasion to consult each other.

(Improvement #2)

At the beginning of Exercise Swarmer there seemed to be some doubt as to

THIS PAGE IS DECLASSIFIED IAW EO 13526

who should keep a file on the spot reports since some pertained to Intelligence and some to operations. It was finally decided that G-2 Air would pass them to G-3 Air for information and to be returned for G-2 Air files.

See inclosure #2 for a proposed mimographed form to be used to record all spot reports of an operational nature. Recommend that these forms be kept by the Chief G-3 Air Clerk and be entered into the journal at the end of the day as one journal entry. This would give a complete record of targets hit by alert aircraft which would not otherwise appear in the journal.

4. CONCLUSIONS:

a. It seems that G-3 Air adhered to accepted doctrine procedures and techniques during the Exercise as nearly as possible. Some variation from the accepted Doctrine was caused by poor communications to Ground Liaison Officers and other units.

b. The problem served its purpose since it proved that the basic doctrine of Joint Operations was sound and it served to uncover a lot of small problems which can be corrected with a little effort.

c. Full use was made of all capabilities.

5. RECOMMENDATIONS:

a. Equipment.

Recommend that the M209 converter be replaced with some faster means of encoding and decoding messages.

b. Communications:

Recommend that a qualified Officer be appointed to make a study to determine where the trouble lies in the present communications set-up and make recommendations for improvement.

c. Coordination:

Recommend that at the beginning of a shift that the G-3 Air Actions Officer thoroughly brief the Duty and Records Officer on the situation and outline the plans that are going to be put into effect to the best of his knowledge. This would help these two Officers to better perform their mission.

d. Techniques and Procedure:

Negative except for plan outlined in (3) (b) above concerning spot reports.

e. Personnel and Administration:

Recommend that qualified typist be furnished as G-3 Clerks.

Recommend that a small hut be furnished for administration and preparation of reports.

JAMES E. REEVES

JOINT OPERATIONS CENTER
AIR-GROUND OPERATIONS SECTION
POST EXERCISE REPORT-EXERCISE SWARMER

1. STATEMENT AND PURPOSE OF PROBLEM:

G-3 Air Duty Officer on first shift from 0500 to 1300 daily. Charged with receiving and processing mission requests other than reconnaissance, from Corps and Divisions, keeping Ground Liaison Officers, Corps and Divisions informed as to location and changes of the bomb safty line and maintaining the friendly situation on the ground situation map.

2. SUMMARY OF EVENTS:

a. General description of routine operations.

Received all requests for air support other than reconnaissance. These requests were recorded on a special mimographed mission request form in four (4) copies. Upon reciept of a mission request, target was plotted on the ground situation map. The journal entry number of that request was also recorded on the map. This target was then checked in its relation to the front lines and the bomb safty line. The mission request was then submitted to the G-3 Air Actions Officer's hands, the G-3 Air Duty Officer was free to return to his desk and recieve other missions. Kept all Ground Liaison Officers, V Corps, and Divisions informed as to the location of the bomb safty line and any changes that occurred in its location.

Maintained the friendly situation on the ground situation map at all times.

In addition to the above, the G-3 Air Duty Officer and the G-3 Air Records Officer, coordinated their effort in keeping a day to day journal on all mission requests, messages, and other events.

b. Description of unusual operations, problems or equipment:

One of the main difficulties encountered was the failure of COS to promptly return a copy of the mission request to AGOS. Missions which were

THIS PAGE IS DECLASSIFIED IAW EO 13526

allotted to air alert aircraft sometimes were never returned until a search was made to locate them in order to close out the journal. It was observed that "On Call" mission requests were returned much faster than "Preplanned" mission requests. TACC was very slow in returning the circulating copy of the mission request which gave information as to the results of the mission. It was noted that there was improvement in this though, as the exercise progressed. Failure of COS to return our copy of the requests promptly, left our records incomplete. Because of this we were unable to keep requesting units posted on the status of their mission requests.

Another problem was having clerks assigned to a shift who were unable to type. Every clerk in the Joint Operations Center should be a typist due to the large volume of reports.

Lack of good, reliable communications hindered the performance of our mission. The basic plan of communications seems sound. That is having radio remoted to the G-3 Air Duty Officer with a Ground Liaison Officers net and a G-3 requests net. During the exercise these nets were always overloaded and most messages had to be sent C.W. with an operational priority. It seems that everyone was using an operational priority though because before the end of the exercise this priority did not mean much as far as getting a message through faster was concerned.

Several messages of an administrative nature were filed in the G-3 air journal. I believe that this should not be done as it tends to make the journal more a scrapbook of routine information than a journal of accurate operational data for which it is intended.

3. DISCUSSION:

a. Opinion on facts:

In my opinion, the physical layout of the Joint Operations Center, as operated during exercise swarmer, is not the correct answer. Due to the congestion

0566

THIS PAGE IS DECLASSIFIED IAW EO 13526

of the Joint Operations Center, it should be set up to avoid as much movement as possible in each person's performance of his mission. As presently set up, the G-3 Air Duty Officer after receiving a mission request, has to move completely around the room to get to the ground situation map. If he has to make notes while at the map, he must use someone else's desk to do so. If the G-3 Air Actions Officer has some information for the Duty Officer, he either has to shout for him to come to his desk, shout the information to him, or get up and go to his desk. If the Actions Officer wants information from the journal, he has to go through one of the above processes with the G-3 Air Clerk. This happens frequently and thereby adds to the confusion within the Joint Operations Center.

b. Description of newly proposed improvements (Improvement #1) (See inclosure #1 for proposed lay-out of JOC).

If the lay-out of the Joint Operations Center was set up as proposed in the inclosed sketch, the G-3 Air Section would be near enough to the G-3 Air Actions Officer for him to be able to converse with any member of the section in a normal tone of voice thereby saving noise and movement within the Joint Operations Center. In this set-up the G-3 Air Actions Officer and the Senior Operations Officer could see the ground situation map without moving from their position. Upon receiving a mission request, the G-3 Air Duty Officer would only have to turn around, plot the trget, and hand it to the G-3 Air Actions Officer without moving from his general area.

One argument which has been raised against this proposal is this: That the Ground Officer and his counter part in the Air Force should sit side by side. During Exercise Swarmer there was no indication that they should be seated in that manner. Since the G-3 Air Actions Officer submitted all requests to the C.O.S., the Ground, and Air Duty Officers had no occasion to consult each other.

(Improvement #2)

At the beginning of Exercise Swarmer there seemed to be some doubt as to

0567

THIS PAGE IS DECLASSIFIED IAW EO 13526

who should keep a file on the spot reports since some pertained to Intelligence and some to operations. It was finally decided that G-2 Air would pass them to G-3 Air for information and to be returned for G-2 Air files.

See inclosure #2 for a proposed mimographed form to be used to record all spot reports of an operational nature. Recommend that these forms be kept by the Chief G-3 Air Clerk and be entered into the journal at the end of the day as one journal entry. This would give a complete record of targets hit by alert aircraft which would not otherwise appear in the journal.

4. CONCLUSIONS:

a. It seems that G-3 Air adhered to accepted doctrine procedures and techniques during the Exercise as nearly as possible. Some variation from the accepted Doctrine was caused by poor communications to Ground Liaison Officers and other units.

b. The problem served its purpose since it proved that the basic doctrine of Joint Operations was sound and it served to uncover a lot of small problems which can be corrected with a little effort.

c. Full use was made of all capabilities.

5. RECOMMENDATIONS:

a. Equipment.

Recommend that the M209 converter be replaced with some faster means of encoding and decoding messages.

b. Communications:

Recommend that a qualified Officer be appointed to make a study to determine where the trouble lies in the present communications set-up and make recommendations for improvement.

c. Coordination:

Recommend that at the beginning of a shift that the G-3 Air Actions Officer thoroughly brief the Duty and Records Officer on the situation and outline the plans that are going to be put into effect to the best of his knowledge. This would help these two Officers to better perform their mission.

d. Techniques and Procedure:

Negative except for plan outlined in (3) (b) above concerning spot reports.

e. Personnel and Administration:

Recommend that qualified typist be furnished as G-3 Clerks.

Recommend that a small hut be furnished for administration and preparation of reports.

File

JOINT OPERATIONS CENTER
AIR-GROUND OPERATIONS SECTION
POST EXERCISE REPORT-EXERCISE SWARMER

I. The problem consisted of operating as a G-3 Action Officer in the AGOS of of the JOC of a Tactical Air Force operating with an Airborne Corps in a totally Airborne operation. The purpose of the problem was to test:

a. The feasibility of operating the JOC of a Tactical Air Force at Corps level with the Tactical Air Force used principally in direct support of the Ground Forces.

b. The procedures set forth in the present doctrine established for an operating JOC.

c. The communications feasibilities presently available to JOC.

d. Liaison between Ground Force and Air Force.

e. The practicability of the present manning level of JOC.

f. The practicability of present administrative functions of the JOC as established by the doctrine.

II. Summary of Events

a. Order of events

(1) Instruction was received in JOC doctrine, duties of AGOS personnel, communications facilities of AGOS, coordination with AFOS, processing of pre-arranged and on call missions, and physical set up of JOC.

(2) Move to field with TAF.

(3) Planning stage operations of AGOS in period prior to an air assault.

(4) Operation of AGOS during air assault of Airborne Corps.

(5) Operation of AGOS during ground operations.

(6) End of Maneuver.

b. Routine operations of the G-3 Air Action Officer consisted of supervision of the preparation of the daily summary report after 2400 for the days events; checking the Air Force Operations order to insure that preplanned

0572

missions were included in the order and were corect; processing of mission requests received too late to be included in the Air Force operations order, and coordinating with the air operations Officer in having these requests flown; and, through cooporation with the air operations Officer, making decisions on cancellation of certain targets, when weather conditions or enemy action reduced the available air effort so as to interfere with preplanned missions.

During daylight hours the Action Officer processed on call requests for missions to be flown in direct support of ground forces; coordinated with the operations Officer on targets to be hit by alert aircraft, on call aircraft, or diversion of aircraft to more important targets; received spot reports and determined wether the target should be hit immediately with available aircraft or available Artillery, and took appropriate action; referred intelligence information to the G-2 Air section; supervised forwarding of information to requesting agencies concerning requests for air support; supervised posting of front lines, boundaries, bomb safety lines, and targets on operations map; Attended evening planning conference; made recommendations to G-3 air concerning preplanned missions, allocation of air effor for the following days operations, and bomb safety lines; and, supervised the maintenance of the journal:

c. Unusual operations, problems, or equipment:

Due to the type of operation conducted, many problems arose that may usually occur, first: in a totally Airborne operation less Artillery was available for support than the Infantry normally expects. Consequently, the Air Force assumed the role of direct support Artillery instead of its normal role of Army Artillery. Perticularly in the early phases of the operation. Missions were flown on targets that would normally have been attacked by Corps or Division Artillery, and in some instances by mortars or recoilless weapons.

0573

Second: The JOC did not accompany the Corps on the air landing, which may or may not be normal in a similar combat operation, consequently the lines of communications between JOC, Corps Headquarters, and Divisions became considerably extended, and caused communications difficulties in the operation.

Third: Communications difficulties were experienced in the employment of the 20 to ACL. In sufficiently trained personnel and antignated equipment could not support the communications load of the operation. Perticular difficulty was experienced in the use of the M-209 converter for encoding and decoding messages.

Fourth: No Corps FSCC was employed in the operation which resulted in the by passing of this important part of the AGOS System.

3. a. Opinions of the reporter on facts:

(1) The personnel attached to AGOS for Exercise SWARMER were insufficiently trained in the details of their respective duties in the operation of the AGOS prior to the Maneuver.

(2) There was a lack of cooperation and coordination between the sections of the AGOS and between the AGOS and the AFOS.

(3) Communications facilities were inadegnate for the efficient operation of the AGOS.

(4) A detailed operating procedure for handling the various missions and administrative functions of the AGOS was not established prior to the operation.

b. Opinions of other observers on the above facts were not recorded.

c. Description of newly proposed improvements.

(1) Use of a purely operations map for the purpose of plotting friendly front lines, boundries, bomb safety lines, objectives, and targets.

0574

THIS PAGE IS DECLASSIFIED IAW EO 13526

map should be of a scale appropriate to the magnitude of the front to be covered during the operation. A map of a scale of 1/25,000 could be utilized in a localized situation such as Swarmer, maps of 1/50,000 or 1/100,000 should be used in operations covering large land masses or large zone of operations.

(2) Establishement of direct land lines to GHQ's, Corps, and Divisions. Duty Officer and Clerk equipped with headset and on a common simple switchboard into which direct lines are connected. Communications established with interested parties simply by making a connection.

(3) Minor rearrangement of AGOS (See annex #1)

CONCLUSIONS:

a. As far as can be determined there were no serious departures from the procedures and techniques laid down in the doctrine except as were dictated by necessity by scope of the problem. A TAF operating with a Corps instead of an Army is in itself a departure from the doctrine. Also because of the peculiarities of the specific problem TAF had more AF units assigned than is normal for operation with an army.

b. The problem did serve the purpose for which it was conducted in that it did prove: (1) the feasibility of a TAF operating with an Airborne Corps indirect support of Ground Forces in the role of Artillery. It proved that the AF could carry out this role successfully for a limited length of time in favorable weather.

(2) That the present procedures and techniques established by the doctrine are sound.

(3) Communications facilities available to JOC at present are inadequate.

(4) Liaison between AF and Ground Forces are established on a workable basis.

(5) That the present manning level of JOC is adequate.

(6) Established administrative functions of the JOC are practical.

0575

THIS PAGE IS DECLASSIFIED IAW EO 13526

c. The full capabilities of the ACOS were not utilized as communications difficulties prevented the processing of on call missions in direct support of ground units. After the beginning of the Air assault there was no instance where a front line unit determined their need for air support, submitted the request through normal channels, and received the support in sufficient time to affect the immediate tactical situation of the requesting unit.

d. General Conclusions.

The ACOS operated successfully in the field under a given but unusual situation of a totally Airborne operation. Attached personnel were insufficiently trained in their duties prior to participation in the operation. Communications personnel were insufficiently trained and communications equipment was too antiquated to carry the communications load for the scope of this particular problem. Many of the difficulties that existed would have been overcome if the problem had continued.

4. RECOMMENDATIONS:

a. Equipment : Transportation for the ACOS become organic in the TAF, in order that maintenance can be performed without expanding the manning level of the ACOS.

b. Communications: That a system be devised for direct wire communications between ACOS, GLO's, and supported units. That better encoding and decoding devices be utilized in the ACOS system. That radio equipment be utilized that will insure radio communications between ACOS, GLO's, and supported units.

c. Coordination: That G-3 Air Action Officer be redesignated as Action Officer and be placed in charge of the operating personnel in the operating ACOS on his shift. That CPX's be conducted periodically by the entire system to include Division, and Corps FSCC and the JOC to promote coordination and cooperation.

d. Techniques and procedures: That the techniques and procedures be standardized and as far as possible itemized, to assist personnel in the performance of their duties.

e. Personnel and Administration: That the G-3 Section consist of a G-3 Actions Officer, a Duty Officer, one clerk and a typist on duty in the JOC with a records Officer and clerk at another location. That the G-2 section consist of a combat Intelligence Officer, and clerk in the JOC with other G-2 personnel at another location.

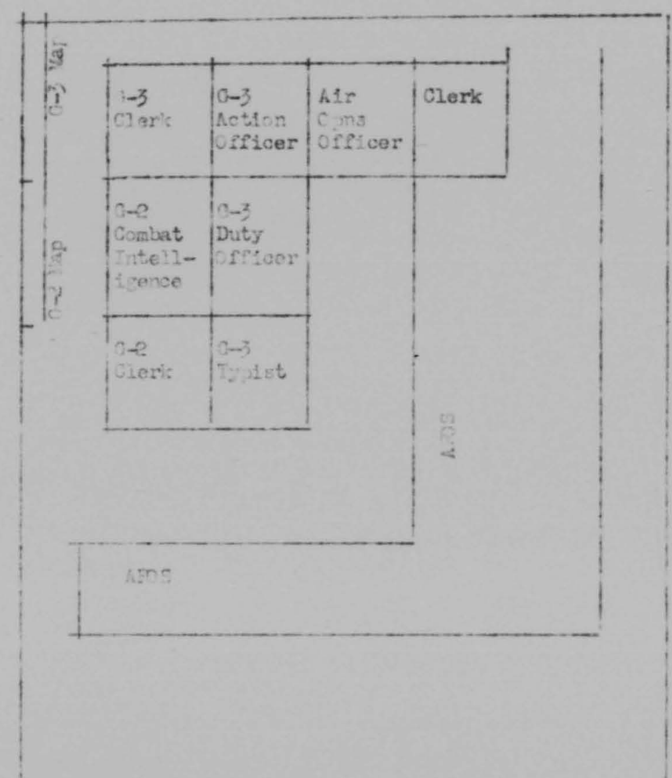
f. That complete lesson plans and training programs be prepared for future instruction of [illegible] personnel.

g. That operational personnel of the [illegible] be relieved of the maintenance of records for historical records, and that this duty be delegated to the most experienced Officer available. This system will allow the operating personnel to carry out their operational duties more efficiently. Also the experienced officer will be able to obtain better material for historical purposes and be able to view the operations objectively without becoming involved in the operations.

J. W. POWERS
Capt F.A.

0577

ANNEX #1



NOTE: G-3 Clerk maintains G-3 map under supervision of G-3 Duty Officer.

NOTE: Other G-3 and G-2 personnel who exist for the purpose of keeping records and for planning purposes, should not be physically in the operating JOC.

THIS PAGE IS DECLASSIFIED IAW EO 13526

AIR GROUND OPERATIONS SECTION

JOINT OPERATIONS CENTER

OPERATIONS

As Headquarters, Swarmer, was concerned over conflicts in AAA control measures prescribed in the Operational Plans of various participants in the Exercise, an AAA Control Conference was called at Swarmer Headquarters, J-3, to coordinate control measures. Such Control measures had already been coordinated between Headquarters, TAF, and and Headquarters, Carolina Base Section, Headquarters, V Corps. Representatives of all interested Headquarters attended and the principles agreed upon by Headquarters, V-Corps, Headquarters, TAF, and Headquarters, CBS, were embodied in the Operational Plans of other affected Headquarters.

Non-availability of airlift precluded the provision of a signal team from the 20th Signal Company Air Ground Liaison for utilization by 3rd Infantry Division (CBX BASES). As a result, it was necessary for the 3rd Infantry Division to process air support requests through V Corps, G-3 Air communications facilities.

In order to expedite submission and processing of air requests, maps of the area overprinted with the 1000 meter grid system utilized by between Air Force units were obtained with distribution to the participating combat ground force units down to and including parachute regimental commanders. As a result the Forward Air Controller and the Ground Force Commanders mentioned above were able to operate from the same type map.

Requirements arose from ground liaison officers and signal teams operating with Air National Guard units for gasoline and similar type

~~services.~~ ~~This was arranged for~~ The necessary coordination was effected through the interested special staff sections. In order to brief all interested air personnel on plans requirements for ~~D-Day~~, a Joint Operations Center briefing team was sent to each of the airfields; Oceana NAS, Va., Langley AFB, Va., Shaw AFB, S.C., Congaree AB, S.C., Morris Field, Charlotte, N.C. Detailed plans, methods of aircraft control, target marking and processing of requests for air support were discussed by representatives of the Air Ground Operations Section and the Combat Operations Section.

The necessity for close coordination of flights of liaison type aircraft was emphasized in the operation. Arrangements were made to coordinate such flights through the Fire Support Coordination Center. As requests for air support passed through this center, it was possible to work out the details of coordination efficiently.

For the purpose of testing ~~the~~ air ~~ground~~ support communications ~~system~~, an Air Ground Communications Exercise was conducted prior to D Day with the participating combat units. During the morning hours, experience was gained in processing requests for air missions within the divisions utilizing aircraft on air alert. Forward Air Controllers with Parachute Infantry Battalions and Regiments actually controlled the aircraft in flight. During the afternoon, requests were submitted for air support by the divisions to the Joint Operations Center utilizing the air ground communications system. Requests were processed in the usual manner and missions flown by the Air Force.

Final coordination of air support requirements for D ~~minus~~-1 and D-Day was effected at a conference attended by representatives of interested commands.

Field testing of grenades, rifle, smoke, colored and various colored

0587

panels was undertaken by this office, ~~504th Airborne~~ Infantry ~~Regiments~~, and AFF Board No. 1 at the instance of the ~~Chief~~ ~~of~~ Army Field Forces. Results valuable to air ground operations were obtained.

In order to provide air strikes ~~effectiveness~~ against enemy targets discovered by fighter or reconnaissance pilots, a system was evolved in which spot reports were passed by the ~~combat operations officer~~ ~~xxxx~~ to the G-3 Air Action Officer who had ~~their~~ coordinates ~~checked~~ and determine desirability of laying on a strike. In the event that such a strike was decided upon, ~~a~~ request was ~~prepared on message form~~ and passed to an Air Target Officer, a specially designated officer in the Combat Operations Section charged with responsibility for processing ~~xxxxx~~ such requests immediately to the Chief Controller of the Tactical Air Control Center. Required aircraft, if available, were directed to such targets.

The question of who should decide where effort is to be placed on purely ground targets was posed by a situation in which enemy targets were reported by friendly aircraft proceeding toward the drop zone of ~~the~~ U.S. Airborne Division. As the tanks were sufficiently distant from the drop zone to constitute no imminent threat, considering time and distance factors, it was recommended that tanks be kept in view by reconnaissance aircraft. ~~be~~ ~~not~~ attacked by air alert aircraft. ~~unless~~, ~~the~~ aircraft on ground alert which had been ordered to take off to attack the target. ~~failed~~ to reach the area in sufficient time to prevent the tanks making contact with friendly forces. As an overall first priority had been prescribed for enemy tanks as ground targets, ~~and~~ immediate diversion of air alert aircraft was directed by Commander, TAF. As this would result in the airborne units being without air support in those critical hours immediately following their parachute landing, the G-3 Air ~~objection~~ to such a diversion ~~was~~ presented

0588

to the Commander, TAF. At that particular time, aircraft became available from an unexpected source, thus obviating the necessity for such a diversion.

Undoubtedly, the most vital problem faced in Exercise SWARMER in air ground coordination was xxxxxxxxx over-coming the inadequacy of the facilities of the 20th Signal Company, Air Ground Liaison. Operating with antiquated cypher devices, the converter, M209, and inexperienced cryptographic and communications personnel, the effective operation of the air ground team was very seriously hampered. Processing of encoded messages from Joint Operations Center to participating divisions, to include acknowledgement of receipt therefore, consumed as much as four hours and thirty-eight minutes. As it was impossible to use voice in most instances, a barrier was created which was never eliminated. Messages transmitted in the clear xxx required an excessive amount of time. The burden of administrative traffic and transmission of operational summaries over this net added a further burden to an already over-taxed facility.

The fact that the Forward Air Controllers arrived with the participating divisions at a late date and, in some instances, without their equipment, further contributed to the difficulties experienced in air ground operations. Lack of radio crystals and failure to make early distribution of authentication codes were additional factors impairing smooth coordination of air ground efforts.

During the period 30 April - 3 May 50 the Joint Operations Center received 212 Pre-planned Mission Requests and 15 On-Call Requests. Of the total of 227 requests received, 152 were completely processed and laid on by the Air Force. The 75 requests not laid on are broken down as follows:

20 were cancelled due to weather; 7 were cancelled by the Commanding General, V Corps; 10 were cancelled because they had previously been planned or laid on; 2 were cancelled after Visual Recce had been flown and no target located; 25 were disapproved by the G-3 Air Action Officer and 9 were

disapproved by the Combat Operations Officer. The total of 34 that were disapproved generally fall within one of the following classes; 1. Target of insufficient importance for Air Strike; 2. No allocation of aircraft available; 3. ~~Administrative Restriction~~ Problem limitations prohibiting accomplishment of ~~Mission~~ Requests.

The lack of time in which to compile this report precluded a thorough study of the operational phase of the exercise, and thus, has resulted in a report entirely inadequate to cover an ~~operation~~ exercise of this magnitude and importance.

RECOMMENDATIONS:

Control measures for anti-aircraft artillery fires should be included in early operational planning of all Headquarters and completely coordinated with all interested echelons prior to publication of their respective plans.

Airlift requirements for signal teams of the Signal Company, Air Ground Liaison should be ~~included~~ predicated to allow for their early arrival by the organizations with which they ~~are serving~~ to serve in the airhead.

Plans for the distribution of maps to Army units should include provisions for supplying such units with maps currently in use by Tactical Air Force, Air Support Aircraft, distributed down to and including line battalion commanders.

Provisions for supplying administrative and logistical services to such elements of the air ground operations system as may be serving with National Guard units should be coordinated with interested agencies prior to dispatch of such elements.

Joint Operations Center Briefing teams ~~in the JOC~~ should be sent to participating air and ground units to thoroughly acquaint ~~brief~~ them ~~on~~ with detailed plans of the operation. Coordination of flights of liaison type aircraft with those of high performance aircraft should be provided for in the operational plans of the interested Headquarters.

Successive air ground communications exercises should be conducted with a participating combat unit sufficiently prior to D-Day to permit correction of deficiencies noted and to afford maximum experience in processing air requests. Forward Air Controllers require additional experience in controlling aircraft prior to the mounting of an operation.

Maximum use should be made of maneuvers and exercises to field test new items of equipment.

A simple abbreviated form should be developed for use in processing requests for air strikes based on spot reports obtained from fighter and reconnaissance pilots in order that a permanent record may be available on one form of all information pertaining to such requests.

~~The representatives of~~ the ground commander ~~(G-2 Air and G-3 Air)~~ should have responsibility of final decision in determining an attack by aircraft against a purely ground target.

The best signal equipment currently available should be furnished by the 20th Signal Company, Air Ground Liaison, to enable them to meet their requirements furnishing expeditious air ground communications. Concerted effort should be placed upon research and development of electronic equipment capable of providing immediate, dependable and sincere air ground communications.

Forward Air Controllers and their equipment~~, completely~~ operative should ~~arrive~~ at the participating organizations at an early date in order to facilitate final phase training and participation in air ground communications exercises.

On-Call mission requests ~~must be submitted in larger numbers~~ in order to conserve available aircraft, but the processing of such requests require the communications system of the caliber outlined above. Pre-planned

Subject: Report on ORT Conference of 18 April 1950

AI 333.1 (10 May 50) 1st Ind 14 Jun 1950

HQ CONTINENTAL AIR COMMAND, Mitchel Air Force Base, New York

TO: The Inspector General, USAF, Hq United States Air Force
Washington 25, D. C.

1. In compliance with paragraph 3, basic letter, the changes recommended by this headquarters to item 28 of the present ORT criteria are attached as Inclosures 1 thru 8.

2. A narrative description of the manner of accomplishment of each phase should be made in the report, to include all matters preventing the effective accomplishment of the mission and the reasons therefor. Also, a rating of satisfactory or unsatisfactory should be awarded each item.

3. Case reports should be utilized where major irregularities and/or deficiencies exist which adversely affect the accomplishment of the unit mission.

4. It is recommended that an actual combat effectiveness score be awarded each unit and an explanation be included as to the basis upon which the score was awarded. This may be included on the cover sheet or as a final paragraph to the operational test sheet.

SCORE SHEET FOR INTERCEPTOR - FIGHTER UNITS

1. SUSTAINED OPERATIONS - The ability to perform eight sorties per aircraft during a four-day period, utilizing 70% of the assigned aircraft twice daily. Aircraft committed must be combat ready.

2. FORMATION FLYING - The ability to maintain the integrity of a formation in accordance with sound tactics and techniques in all maneuvers within the limitations of the aircraft and the size of the formation employed. The unit must be capable of take-off, assembly and landing formations of various sizes in accordance with requirements of the unit training standard.

3. NAVIGATION - The ability to accomplish precision, maximum range navigational flights at the effective combat altitude of the aircraft; duration of each navigation sortie must be 90% of the fuel range specified in AF publications, less normal take-off and landing periods. Each aircraft must make good its ETA within 5% of the estimated total flight time.

4. INSTRUMENT FLYING

a. Individual

(1) Number of assigned pilots who hold a current USAF instrument rating.

(2) The ability to take off, climb, navigate, descend and land under minimum weather conditions, utilizing all available radio aids.

Incl #1

THIS PAGE IS DECLASSIFIED IAW EO 13526

Score Sheet for Interceptor-Fighter Units (contd)

b. Element and flight formation - The ability of a unit to penetrate weather by elements or flights with the wing man and/or second element maintaining position by visual reference to the lead aircraft.

c. Squadron penetration - The ability to ascend or descend through an overcast, utilizing time and space separation factors between flights with an orderly rendezvous above or below the overcast.

5. NIGHT FLYING - The ability to operate individually or by elements during the hours of darkness.

6. AERIAL GUNNERY - The ability of each pilot to fire and qualify in accordance with unit training standard. In the event it is not possible to conduct actual firing during the period of the ORT, a check of the records will be made to determine the number of pilots who have qualified during qualification firing within the previous year.

7. INTERCEPTION - The ability to operate in an air defense system under the direction of a ground controller. This includes the capability of immediate and precise execution of directions from the ground controller for changes in speed, vectors and altitudes, establishment of visual contact with the target, and

THIS PAGE IS DECLASSIFIED IAW EO 13526

employment of sound aggressive tactics in the attack. Scrambles from various stages of alert and ascent to altitude within time limits prescribed in appropriate unit training standard.

8. TURN-AROUND MISSIONS - The ability of the unit to service aircraft participating in turn-around missions within the time limits prescribed in applicable unit training standard.

9. RADIO PROCEDURES AND DISCIPLINE - Thorough knowledge and employment of established radio procedures (including appropriate JANAP's) and maintenance of air discipline.

10. NORMAL AND EMERGENCY PROCEDURES - Familiarity of pilots with normal and emergency procedures necessary for the operation of the aircraft. (Oxygen, pressurization, anti-G suits, crash-landing and ditching, etc.)

11. BRIEFING AND CRITIQUE - The ability to conduct efficient combat crew briefing and interrogation.

12. INTELLIGENCE

a. The ability to collect, collate, evaluate and disseminate military information in accordance with established procedures.

THIS PAGE IS DECLASSIFIED IAW EO 13526

Score Sheet for Interceptor-Fighter Units (contd)

b. Knowledge of the characteristics and recognition features of potentially hostile aircraft and missiles.

SCORE SHEET FOR FIGHTER-BOMBER UNITS

1. SUSTAINED OPERATIONS - The ability to perform eight sorties per aircraft during a four-day period, utilizing 70% of the assigned aircraft twice daily. Aircraft committed must be combat ready.

2. FORMATION FLYING - The ability to maintain the integrity of a formation in accordance with sound tactics and techniques in all maneuvers within the limitations of the aircraft and the size of the formation employed. The unit must be capable of take-off, assembly and landing formations of various sizes in accordance with requirements of the unit training standard.

3. NAVIGATION -

a. The ability to accomplish precision navigational flights at medium and effective combat altitude of the aircraft. Duration of each navigation sortie must be 90% of the fuel range specified in AF publications, less normal take-off and landing periods. Each aircraft must make good its ETA within 5% of the estimated total flight time.

b. The ability to navigate at very low altitude and locate predesignated pin-point targets.

Incl #2

0601

4. INSTRUMENT FLYING

   a. Individual

      (1) Number of assigned pilots who hold a current USAF instrument rating.

      (b) The ability to take off, climb, navigate, descend and land under minimum weather conditions utilizing all available radio aids.

   b. Element and flight formation - The ability of a unit to penetrate weather by elements or flights with the wing man and/or second element maintaining position by visual reference to the lead aircraft.

   c. Squadron penetration - The ability to ascend or descend through an overcast, utilizing time and space separation factors between flights with an orderly rendezvous above or below the overcast.

5. NIGHT FLYING - The ability to operate individually or by elements during the hours of darkness.

6. AERIAL GUNNERY - The ability of each pilot to fire and qualify in accordance with unit training standard. In the event it is not possible to conduct actual firing during the period of the ORT, a check of the records will be made to determine the number of pilots who have qualified during qualification firing within the previous year.

THIS PAGE IS DECLASSIFIED IAW EO 13526

Score Sheet for Fighter-Bomber Units (contd)

7. GROUND GUNNERY - The ability to fire upon a standard ground gunnery target and qualify in accordance with unit training standard. In the event it is not possible to conduct actual firing during the period of the ORT, a check of the records will be made to determine the number of pilots who have qualified during qualification firing within the previous year.

8. ROCKETRY - The ability to fire rockets upon a standard target and qualify in accordance with unit training standard. In the event it is not possible to conduct actual firing during the period of the ORT, a check of the records will be made to determine the number of pilots who have qualified during qualification firing within the previous year.

9. DIVE BOMBING - The ability to bomb and qualify in accordance with unit training standard. In the event it is not possible to conduct actual firing during the period of the ORT, a check of the records will be made to determine the number of pilots who have qualified during qualification firing within the previous year.

10. OPERATIONS UNDER RADAR CONTROL

a. The ability to accomplish interceptions of airborne targets under the direction of a ground controller. This includes the capability of immediate and precise execution of directions from the ground controller for changes in speed, vectors and altitudes, establishment of visual contact with the target and employment of sound aggressive tactics in the attack.

b. The ability to attack with guns, bombs and rockets enemy troops, installations and ground equipment, while under the direction of a forward controller and/or other units of a tactical control system.

11. RADIO PROCEDURES AND DISCIPLINE - Thorough knowledge and employment of established radio procedures (including appropriate JANAP's) and maintenance of air discipline.

12. NORMAL AND EMERGENCY PROCEDURES - Familiarity of pilots with normal and emergency procedures necessary for the operation of the aircraft. (Oxygen, pressurization, anti-G suits, crash-landing and ditching.)

13. BRIEFING AND CRITIQUE - The ability to conduct efficient combat crew briefing and interrogation.

14. INTELLIGENCE

a. The ability to collect, collate, evaluate and disseminate military information in accordance with established procedure.

THIS PAGE IS DECLASSIFIED IAW EO 13526

Score Sheet for Fighter-Bomber Units (contd)

b. Knowledge of the characteristics and recognition features of potentially hostile aircraft, missiles, and ground equipment and installations.

c. Knowledge of the capabilities and limitations of antiaircraft artillery and radar.

THIS PAGE IS DECLASSIFIED IAW EO 13526

SCORE SHEET FOR ALL-WEATHER FIGHTER UNITS

1. SUSTAINED OPERATIONS - The ability to furnish 70% of assigned aircraft in a combat ready condition to the AC&W controller for the fulfillment of his requirements.

2. NAVIGATION - The ability to accomplish precision, maximum range navigational flights under instrument conditions, actual or simulated (the latter to be used when actual instrument conditions do not prevail) at the effective combat altitude of the aircraft. Duration of each navigation sortie must be 90% of the fuel range specified in AF publications, less normal take-off and landing periods. Each aircraft must make good its ETA within 5% of the estimated total flight time.

3. INSTRUMENT FLYING

a. Number of assigned pilots who hold a current USAF instrument rating.

b. The ability to take off, accomplish any mission required of all-weather fighter aircraft and land under minimum weather conditions, utilizing all available radio and electronic aids.

4. NIGHT FLYING - The ability to conduct any mission required of all-weather fighter units under conditions of darkness.

Incl #3

0606

Score Sheet for All-Weather Fighter Units (contd)

5. AERIAL GUNNERY - The ability of each pilot to fire and qualify in accordance with unit training standard (day and night). In the event it is not possible to conduct actual firing during the period of the ORT, a check of the records will be made to determine the number of pilots who have qualified during qualification firing within the previous year.

6. INTERCEPTION - The ability to operate in an air defense system under the direction of a ground controller. This includes the capability of immediate and precise execution of directions from the ground controller for changes in speed, vectors and altitudes, assumption of AI control and tracking, positioning and attacking the target by use of airborne electronic equipment. Scrambles from various stages of alert and ascent to altitude within time limits prescribed in appropriate unit training standard.

7. TURN-AROUND MISSIONS - The ability of the unit to service aircraft participating in turn-around missions within the time limits prescribed in applicable unit training standard.

8. RADIO PROCEDURES AND DISCIPLINE - Thorough knowledge and employment of established radio procedures (including appropriate JANAP's) and maintenance of air discipline.

Score Sheet for All-Weather Fighter Units (contd)

9. NORMAL AND EMERGENCY PROCEDURES - Familiarity of pilots with normal and emergency procedures necessary for the operation of the aircraft. (Oxygen, pressurization, anti-G suits, crash-landing and ditching, etc.)

10. BRIEFING AND CRITIQUE - The ability to conduct efficient combat crew briefing and interrogation.

11. INTELLIGENCE

a. The ability to collect, collate, evaluate and disseminate military information in accordance with established procedure.

b. Knowledge of the characteristics and recognition features of potentially hostile aircraft and missiles.

THIS PAGE IS DECLASSIFIED IAW EO 13526

SCORE SHEET FOR LIGHT BOMBARDMENT (B-45) UNITS

1. SUSTAINED OPERATIONS - Unit must be capable of performing three missions of normal combat radius for the B-45 type aircraft within a four-day period, utilizing an average of 70% of the assigned aircraft per mission.

2. ASSEMBLY AND FORMATION

   a. The ability to take off and assemble a 12-aircraft formation under VFR conditions within 10 minutes.

   b. The ability to land a 12-aircraft formation under VFR conditions within six minutes.

   c. The ability to maintain the integrity of a formation in all maneuvers within the limitations of the aircraft and the size of the formation employed.

3. NAVIGATION - The ability to accomplish precision, maximum range navigational flights at medium and high altitudes, utilizing electronic aids and dead-reckoning. Duration of each navigation sortie must be 90% of the fuel range specified in AF publications, less normal take-off and landing periods. Each aircraft must make good its ETA within 5% of the estimated total flight time.

4. INSTRUMENT FLYING

   a. Number of assigned pilots who hold a current USAF instrument rating.

Incl #4

THIS PAGE IS DECLASSIFIED IAW EO 13526

Score Sheet for Light Bombardment (B-45) Units (contd)

b. The ability to take off, ascend, navigate, descend and land under minimum weather conditions utilizing all available radio and electronic aids.

c. The ability to take off individually, ascend through an overcast and assemble 12 aircraft in formation above the overcast.

5. NIGHT FLYING - The ability to operate individually and/or in formation on tactical missions during the hours of darkness.

6. BOMBING - The ability to locate, identify and accurately bomb briefed targets.

7. OPERATIONS UNDER RADAR CONTROL - The ability to attack targets in the vicinity of friendly troops while operating under the direction of a forward controller and/or other units of a tactical control system.

8. RADIO PROCEDURES AND DISCIPLINE - Thorough knowledge and employment of established radio procedures (including appropriate JANAP's) and maintenance of air discipline.

9. NORMAL AND EMERGENCY PROCEDURES - Familiarity of pilots with normal and emergency procedures necessary for the operation of the aircraft. (Oxygen, pressurization, crash-landing and ditching, etc.)

Score Sheet for Light Bombardment (B-45) Units (contd)

10. BRIEFING AND CRITIQUE - The ability to conduct efficient combat crew briefing and interrogation.

11. INTELLIGENCE

a. The ability to collect, collate, evaluate and disseminate military information in accordance with established procedure.

b. Knowledge of the characteristics and recognition features of potentially hostile aircraft and missiles, and ground equipment and installations.

THIS PAGE IS DECLASSIFIED IAW EO 13526

SCORE SHEET FOR TACTICAL RECONNAISSANCE UNITS

1. SUSTAINED OPERATIONS - The ability to keep an average of 70% of assigned aircraft combat ready during period of test.

2. NAVIGATION - The ability to accomplish precision, maximum range navigational flights, utilizing electronic aids and dead-reckoning. Duration of each navigational sortie must be 90% of the fuel range specified in AF publications, less normal take-off and landing periods. Each aircraft must make good its ETA within 5% of the estimated total flight time.

3. INSTRUMENT FLYING -
   a. Number of assigned pilots who hold a current USAF instrument rating.
   b. Ability to take off, climb, navigate, descend, and land under minimum weather conditions, utilizing all available radio aids.

4. NIGHT FLYING - The ability to operate during the hours of darkness within the scope of night operations required of tactical reconnaissance units.

5. VISUAL RECONNAISSANCE
   a. The ability to conduct visual reconnaissance and report information on location and/or movement of ground and naval surface formations, equipment and installations.

Incl #5

THIS PAGE IS DECLASSIFIED IAW EO 13526

Score Sheet for Tactical Reconnaissance Units (contd)

b. The ability to operate with accuracy in conjunction with artillery and naval units on adjustment missions.

6. PHOTOGRAPHIC RECONNAISSANCE

a. The ability to obtain photographic coverage of pin-point targets, strips and mosaics by use of all types of camera installations capable of being employed in the aircraft.

b. The ability to develop, print and provide first phase photo interpretation within time required by unit training standard after completion of a mission.

7. RADIO PROCEDURES AND DISCIPLINE - Thorough knowledge and employment of established radio procedures (including appropriate JANAP's) and maintenance of air discipline.

8. NORMAL AND EMERGENCY PROCEDURES - Familiarity of pilots with normal and emergency procedures necessary for the operation of the aircraft. (Oxygen, pressurization, crash-landing and ditching, etc.)

9. BRIEFING AND CRITIQUE - The ability to conduct efficient combat crew briefing and interrogation.

10. INTELLIGENCE AND MISSION PLANNING

Score Sheet for Tactical Reconnaissance Units (contd)

a. The ability to collect, collate, evaluate and disseminate military information in accordance with established procedures.

b. Knowledge of the characteristics and recognition features of potentially hostile aircraft, missiles, and ground equipment and installations.

c. The ability to plan, coordinate, dispatch and supervise missions directed by higher headquarters.

11. TURN-AROUND MISSIONS - The ability of the unit to service aircraft participating in turn-around missions within the time limits prescribed in applicable unit training standard.

THIS PAGE IS DECLASSIFIED IAW EO 13526

SCORE SHEET FOR TROOP CARRIER UNITS (MEDIUM)

1. SUSTAINED OPERATIONS - The ability of the unit to keep 75% of the assigned aircraft in the air for the missions required during the four-day period of the test. (A minimum of 3 missions to be scheduled.)

2. FORMATION FLYING

   a. The ability to take off and assemble a nine-aircraft formation under VFR conditions within eight minutes.

   b. The ability to take off and assemble a nine-aircraft formation with gliders (for units so equipped) under VFR conditions within 14 minutes.

   c. The ability to maintain the integrity of a formation in accordance with troop carrier tactics and techniques during all maneuvers within the limitations of the aircraft and the size of the formation employed.

   d. The ability to land a nine-aircraft formation under VFR conditions within seven minutes.

3. NAVIGATION - The ability to accomplish precise, maximum range navigational flights, arriving over a designated point within one minute of the briefed time.

4. INSTRUMENT FLYING

   a. Individual

Incl #6

THIS PAGE IS DECLASSIFIED IAW EO 13526

(1) Number of assigned pilots who hold a current USAF instrument rating.

(2) The ability to take off, climb, navigate, descend and land under minimum weather conditions utilizing all available radio aids.

b. Element and Flight Formation - The ability of a unit to penetrate weather by elements or flights with the wing man and/or second element maintaining position by visual reference to the lead aircraft.

c. Squadron penetration - The ability to ascend or descend through an overcast, utilizing time and space separation factors between flights with an orderly rendezvous above or below the overcast.

5. NIGHT FLYING - The ability to operate individually and in formation on tactical missions during the hours of darkness.

6. PARATROOP OPERATIONS

a. The ability to locate a DZ through utilization of pathfinder equipment and techniques, and by use of maps and photos; and the ability to deliver an airborne unit to the designated DZ within one minute of the briefed time.

b. The ability to utilize appropriate formation and to position and drop troops into a limited area, the size of which will

THIS PAGE IS DECLASSIFIED IAW EO 13526

be commensurate with the assigned tactical mission.

7. RESUPPLY

a. The ability to deliver supply bundles by parachute into a limited area, the size of which will be commensurate with the tactical mission.

b. The ability to deliver troops and equipment into a designated air landing area on schedule.

8. GLIDER OPERATIONS (FOR UNITS SO EQUIPPED)

a. The ability to take off, assemble in formation and deliver gliders to a designated landing zone within one minute of the briefed time over target.

b. The ability to conduct glider pick-up operations in accordance with standard troop carrier tactics and techniques.

9. AIR EVACUATION - The ability to conduct air evacuation missions, including the setting up of litters and equipment, in-flight feeding, and proper procedure for care of sick and wounded.

10. RADIO PROCEDURES AND DISCIPLINE - Thorough knowledge and employment of established radio and interphone procedures (including appropriate JANAP's), and maintenance of air discipline.

THIS PAGE IS DECLASSIFIED IAW EO 13526

11. NORMAL AND EMERGENCY PROCEDURES - Thorough knowledge of all normal and emergency procedures applicable to the safe operation of the aircraft; knowledge of the methods of abandoning, crash-landing and ditching the aircraft; familiarity with the proper use of life-saving equipment with which provided.

12. BRIEFING AND CRITIQUE - The ability to conduct efficient combat crew briefing and interrogation.

13. INTELLIGENCE - The ability to collect, collate, evaluate and disseminate military information in accordance with established procedures.

THIS PAGE IS DECLASSIFIED IAW EO 13526

SCORE SHEET FOR TROOP CARRIER UNITS (HEAVY)

1. SUSTAINED OPERATIONS - The ability of the unit to keep 75% of the assigned aircraft in the air for the missions required during the four-day period of the test. (A minimum of 3 missions to be scheduled.)

2. FORMATION -

   a. The ability to take off and assemble a six-aircraft formation under VFR conditions within eight minutes.

   b. The ability to maintain the integrity of a formation in accordance with troop carrier tactics and techniques during all maneuvers within the limitations of the aircraft and the size of the formation employed.

   c. The ability to land a six-aircraft formation under VFR conditions within five minutes.

3. NAVIGATION - The ability to accomplish precise, maximum range navigational flights, arriving over a designated point within one minute of the briefed time.

4. INSTRUMENT FLYING

   a. Individual

      (1) Number of assigned pilots who hold a current USAF instrument rating.

Fuel #7

(2) The ability to take off, climb, navigate, descend and land under minimum weather conditions, utilizing all available radio aids.

b. Element and Flight Formation - The ability of a unit to penetrate weather by elements or flights with the wing man and/or second element maintaining position by visual reference to the lead aircraft.

c. Squadron penetration - The ability to ascend or descend through an overcast, utilizing time and space separation factors between flights with an orderly rendezvous above or below the overcast.

5. NIGHT FLYING - The ability to operate individually and in formation on tactical missions during the hours of darkness.

6. AIR EVACUATION - The ability to conduct air evacuation missions, including the setting up of litters and equipment, in-flight feeding, and proper procedure for care of sick and wounded.

7. AIRLIFT - The ability to deliver troops and/or equipment into a designated area on schedule and in accordance with the assigned tactical mission.

8. RADIO PROCEDURES AND DISCIPLINE - Thorough knowledge and employment of established radio and interphone procedures (including

appropriate JANAP's) and maintenance of air discipline.

9. NORMAL AND EMERGENCY PROCEDURES - Thorough knowledge of all procedures applicable to the safe operation of the aircraft; knowledge of the method of abandoning, crash-landing and ditching the aircraft; familiarity with the proper use of life-saving equipment with which provided.

10. BRIEFING AND CRITIQUE - The ability to conduct efficient combat crew briefing and interrogation.

11. INTELLIGENCE - The ability to collect, collate, evaluate and disseminate military information in accordance with established procedures.

THIS PAGE IS DECLASSIFIED IAW EO 13526

SCORE SHEET FOR AIRCRAFT CONTROL AND WARNING UNITS

SECTION I - AIR DEFENSE CONTROL CENTER

(Overall effectiveness to be based on applicable TO&E authorizations and assigned mission.)

1. PRESENTATION OF AIR SITUATION - Ability of the control center to present clearly a continuous and timely representation of the air picture. Ability of the unit to collect and disseminate to all control personnel special information concerning the capabilities, limitations and tactics of friendly and hostile forces. Ability of the center to display continuously all applicable air surveillance, aircraft, communications and radar status, movement-identification, and weather information as rapidly as secured.

2. COMMUNICATIONS OPERATIONS - Ability of the unit to utilize efficiently organic communications facilities and equipment. Ability of the unit to transmit information on air activity, as rapidly as collected, to interested installations and agencies. Ability of the unit to utilize all available means to minimize the effects of enemy jamming operations. Adequacy of communications security and net discipline. Adeptness of operating personnel in use of applicable grid systems, codes, authentication systems, and operation logs.

3. IDENTIFICATION - Ability of the unit to identify all friendly aircraft through knowledge of flight plans, radar data and other related information. Expeditious accomplishment of confirmation or changing of hostile identification of tracks after reporting to the control center. Provision for supplying air raid warning information to civilian and military authorities.

Incl #8

0622

THIS PAGE IS DECLASSIFIED IAW EO 13526

4. COMBAT OPERATIONS - Ability of the control center to utilize information of the air situation in effectively employing fighter aircraft and AAA. Ability of the control center to co-ordinate the utilization of all air defense activities within the area, to include the necessary coordination with higher and adjacent units required by mutual air defense operations. Provisions for coordinating and supervising air rescue and navigational assistance to friendly air activity. Coordination and supervision of all air surveillance units in maintaining continuous, complete air surveillance coverage of the area. Ability to conduct efficient briefings and critiques.

5. INTELLIGENCE - Ability of the unit to collect information of all friendly aircraft movements in the area and other intelligence concerning air operations, and analyze, evaluate and disseminate this information to air units or agencies as required.

6. SECURITY - Adequacy of precautionary measures to safeguard equipment and personnel. Establishment of an adequate unit defense plan consistent with organic capabilities.

SCORE SHEET FOR AIRCRAFT CONTROL AND WARNING UNITS

SECTION II - GCI RADAR STATION

(Overall effectiveness to be based on applicable TO&E authorization and assigned mission.)

1. RADAR OPERATIONS - The ability efficiently to operate organic radar and IFF equipment, reporting the data obtained with a minimum time delay according to SOP's. The ability to establish air surveillance of a designated sector to include: detection of aircraft; height determination of tracks; electronic interrogation of tracks; display of position; height; IFF; and estimated number of aircraft. Indoctrination of personnel in the recognition of hostile countermeasures activity and the employment of anti-jamming measures.

2. PRESENTATION OF THE AIR SITUATION - Ability of the unit to present clearly a continuous and timely representation of the air picture. The ability to report to the control center the position, direction, number of aircraft, height and identification, as rapidly as such information is displayed. Effectiveness of cross-telling between stations.

3. COMBAT OPERATIONS - Ability of the unit to utilize properly air information in controlling combat forces. Ability to identify all aircraft in the sector within one minute after display of initial plot. Ability of unit to control two flights simultaneously per control scope, coordinate all air activities within the

sector and with adjoining sectors, provide navigational assistance to friendly aircraft lost or in distress, and provide air raid warning information to civil and military agencies, to include AAA. Ability to conduct efficient briefings and critiques.

4. COMMUNICATIONS OPERATIONS - Ability of the unit to utilize efficiently organic communications equipment. Capability of communications operating personnel to utilize applicable communications operating procedures, as prescribed in USAF publications and JANAP's. Adeptness of operating personnel in use of applicable grid systems, codes, authenticator systems, and operation logs. Adequacy of communications security and net discipline. Employment of correct fighter director R/T code in accordance with JANAP 142B.

5. SECURITY - Adequacy of precautionary measures to safeguard equipment and personnel. Establishment of an adequate unit defense plan consistent with organic capabilities.

0625

SCORE SHEET FOR AIRCRAFT CONTROL AND WARNING UNITS

SECTION III - EARLY WARNING RADAR STATION

(Overall effectiveness to be based on applicable TO&E authorizations and assigned mission.)

1. RADAR OPERATIONS - The ability of the unit efficiently to operate organic radar and IFF equipment; report the data obtained with a minimum time delay according to SOP's; identify all air activity in its area of responsibility within one minute after display of initial plot; obtain and report radar weather information; recognize hostile counter-measures and employ anti-jamming measures; perform intercept missions under VFR conditions and conduct efficient briefings and critiques.

2. COMMUNICATIONS OPERATIONS - The ability of the unit efficiently to utilize organic communications equipment; employ applicable communications operating procedures as prescribed in USAF publications and JANAP's; utilize applicable grid systems, codes, authentication systems and operation logs; rapidly transmit air activity information to all interested agencies or installations; employ adequate communications security and net discipline; coordinate with higher and adjacent units when required for mutual air surveillance operations; and utilize correct fighter director R/T code in accordance with JANAP 142B.

Score Sheet for Aircraft Control and Warning Units (contd)

3. SECURITY - Adequacy of precautionary measures to safeguard equipment and personnel. Establishment of adequate unit defense plan consistent with organic capabilities.

SCORE SHEET FOR TACTICAL CONTROL UNITS - SECTION I -

TACTICAL AIR CONTROL CENTER

(Overall effectiveness to be based on applicable TO&E authorization and assigned mission.)

1. PRESENTATION OF AIR SITUATION - Ability of the control center to present clearly a continuous and timely representation of the air picture. Ability of the unit to collect and disseminate to all control personnel special information concerning the capabilities, limitations and tactics of friendly and hostile forces. Ability of the center to display continuously all applicable air surveillance, aircraft, communications and radar status, movement-identification, and weather information as rapidly as secured.

2. COMMUNICATIONS OPERATIONS - Ability of the unit to utilize efficiently organic communications facilities and equipment. Ability of the unit to transmit information on air activity, as rapidly as collected, to interested installations and agencies. Ability of the unit to utilize all available means to minimize the effects of enemy jamming operations. Adequacy of communications security and net discipline. Adeptness of operating personnel in use of applicable grid systems, codes, authentication systems, and operation logs.

3. IDENTIFICATION - Ability of the unit to identify all friendly aircraft through knowledge of flight plans, radar data and other related information. Expeditious accomplishment of confirmation or changing of hostile identification of tracks after reporting to the control center. Provision for supplying air raid warning information to civilian and military authorities.

Incl #9

4. COMBAT OPERATIONS

a. Ability of the control center to utilize information of the air situation in effectively employing fighter aircraft and AAA. Ability of the control center to coordinate the utilization of all air defense activities within the area, to include the necessary coordination with higher and adjacent units required by mutual air defense operations. Provisions for coordinating and supervising air rescue and navigational assistance to friendly air activity. Coordination and supervision of all air surveillance units in maintaining continuous, complete air surveillance coverage of the area. Ability to conduct efficient briefings and critiques.

b. Offensive. Ability of chief controller, upon receipt of operations orders from joint operations center, to hold briefings during which missions are assigned to individual controllers; adequacy of briefings as to bomb safety lines, friendly air and ground intelligence, enemy air and ground intelligence, particularly enemy AAA positions. Techniques of individual controllers during accomplishment of request or call mission. Ability of controllers to keep fighters and direction centers supplied with the latest target and intelligence information. Ability of the controller in charge of air defense to keep himself continually abreast of the tactical situation as regards routes of friendly fighter aircraft engaged in support missions, and flight plans of friendly cargo, troop-carrying and reconnaissance aircraft; his ability to act as movements-identification officer and utilize this information to assist the tactical air direction centers having direct control of the Combat Air Patrol fighter aircraft. Ability of the control center parties either direct or through the direction centers. Efficiency and dispatch of the chief controller in analyzing a tactical situation, making a command decision thereon, or recommending action to the joint operations center. Utilization to the maximum degree of pin-point radar bombing facilities of the tactical air direction posts.

5. INTELLIGENCE - Ability of the unit to collect information of all friendly aircraft movements in the area and other intelligence concerning air operations, and anlyze, evaluate and disseminate this information to air units or agencies as required.

6. SECURITY - Adequacy of precautionary measures to safeguard equipment and personnel. Establishment of an adequate unit defense plan consistent with organic capabilities.

THIS PAGE IS DECLASSIFIED IAW EO 13526

SCORE SHEET FOR TACTICAL CONTROL UNITS

SECTION II - TACTICAL AIR DIRECTION CENTER

(Overall effectiveness to be based on applicable TO&E authorizations and assigned mission.)

1. RADAR OPERATIONS - The ability efficiently to operate organic radar and IFF equipment, reporting the data obtained with a minimum time delay according to SOP's. The ability to establish air surveillance of a designated sector, to include: detection of aircraft; height determination of tracks; electronic interrogation of tracks; display of position; height; IFF; and estimated number of aircraft. Indoctrination of personnel in the recognition of hostile countermeasures activity and the employment of anti-jamming measures.

2. PRESENTATION OF THE AIR SITUATION - Ability of the unit to present clearly a continuous and timely representation of the air picture. The ability to report to the control center the position, direction, number of aircraft, height and identification, as rapidly as such information is displayed. Effectiveness of cross-telling between stations.

3. COMBAT OPERATIONS

a. Defensive - Ability of the unit to utilize properly air information in controlling combat forces. Ability to identify

THIS PAGE IS DECLASSIFIED IAW EO 13526

all aircraft in the sector within one minute after display of initial plot. Ability of unit to control two flights simultaneously per control scope, coordinate all air activities within the sector and with adjoining sectors, provide navigational assistance to friendly aircraft lost or in distress, and provide air raid warning information to civil and military agencies, to include AAA. Ability to conduct efficient briefings and critiques.

b. Offensive. Ability of chief controller to brief all control personnel upon receipt of operations orders. Adequacy of briefings as to the current ground situation, friendly and enemy air activity, location of bomb-safety lines and concentrations of enemy AAA. Effectiveness in charting of ground situation in assisting individual controllers in carrying out support missions. Ability of individual controllers to supply aircraft with target and en route information during request missions. Ability of the unit during request missions to maintain close contact with the tactical air control parties and to keep them informed well in advance as to the identification, numbers, and approach direction of fighter-bombers. Efficiency and dispatch of the chief controller in analyzing a tactical situation, in making a command decision thereon, or in making recommendations to the tactical air control center.

THIS PAGE IS DECLASSIFIED IAW EO 13526

Score Sheet for Tactical Control Units
Section II - Tactical Air Direction Center (contd)

4. COMMUNICATIONS OPERATIONS - Ability of the unit to utilize efficiently organic communications equipment. Capability of communications operating personnel to utilize applicable communications operating procedures as prescribed in USAF publications and JANAP's. Adeptness of operating personnel in use of applicable grid systems, codes, authenticator systems, and operation logs. Adequacy of communications security and net discipline. Employment of correct fighter director R/T code in accordance with JANAP 142B.

5. SECURITY - Adequacy of precautionary measures to safeguard equipment and personnel. Establishment of an adequate unit defense plan consistent with organic capabilities.

0633

THIS PAGE IS DECLASSIFIED IAW EO 13526

SCORE SHEET FOR TACTICAL CONTROL UNITS

SECTION III - TACTICAL AIR CONTROL PARTY

(Overall effectiveness to be based on applicable TO&E authorization and assigned mission.)

1. COMBAT OPERATIONS - The ability of the unit efficiently to advise army unit commander as to selection of air targets; make sound recommendations on request missions as to aircraft and bomb-load requirements; display good judgment when working directly with supporting aircraft; continually inform pilots as to target movements, enemy automatic weapon and heavy AAA concentrations in the target area, and the position of friendly troops and armor; recommend correct and effective use of marker smoke or flares to assist bomber aircraft; make effective recommendations for the routes of reconnaissance aircraft; and maintain adequate contact with the rear elements of the tactical control group.

2. COMMUNICATIONS OPERATIONS - The ability of the unit efficiently to utilize organic communications equipment; and employ correct voice procedures, security measures and authentication systems. Maintenance of proper radio discipline.

THIS PAGE IS DECLASSIFIED IAW EO 13526

SCORE SHEET FOR TACTICAL CONTROL UNITS

SECTION IV - TACTICAL AIR DIRECTION POST

(Overall effectiveness to be based on applicable TO&E authorization and assigned mission.)

1. COMBAT OPERATIONS - Ability of chief controller to brief all control personnel upon receipt of operations orders. Adequacy of briefings as to the current ground situation, friendly and enemy air activity, location of bomb-safety lines and concentrations of enemy AAA. The ability of the unit efficiently to operate organic radar equipment. Effectiveness in charting ground situation to carry out support missions. The ability to direct aircraft by electronic means to target and when to drop bombs. The ability to direct aircraft in precision navigation. Efficiency and dispatch of the chief controller in analyzing a tactical situation and making recommendations to the tactical air direction center.

2. COMMUNICATIONS OPERATIONS - Ability of the unit efficiently to utilize organic communications equipment. Capability of communications operating personnel to utilize applicable communications operating procedures as prescribed in USAF publications and JANAP's. Adeptness of operating personnel in use of applicable grid systems, codes, authenticator systems, and operations logs. Adequacy of communications security and net

THIS PAGE IS DECLASSIFIED IAW EO 13526

discipline. Employment of correct fighter director R/T code in accordance with JANAP 142B.

3. SECURITY - Adequacy of precautionary measures to safeguard equipment and personnel. Establishment of an adequate unit defense plan consistent with organic capabilities.

AIR FORCE ROTC

TRAINING EVALUATION REPORT

ACADEMIC YEAR 1948–1949

HEADQUARTERS
CONTINENTAL AIR COMMAND
MITCHEL AIR FORCE BASE, NEW YORK

HEADQUARTERS
CONTINENTAL AIR COMMAND
Mitchel Air Force Base, New York

ROTC 334 20 September 1949

SUBJECT: Results of the 1949 Air Force ROTC Evaluation Program

TO : Commanding Generals', Continental Air Command Air Forces

1. Transmitted herewith are the results of the examinations given to Air Force ROTC cadets during the Academic Year 1948-1949 in the following areas:

a. ROTC Qualifying Examination, RQ-3-49-First Year Basic Students.
b. Introduction to USAF - First Year Advanced.
c. Administration and Military Management- Second Year Advanced.
d. Aircraft Maintenance Engineering- Second Year Advanced.
e. Air Force Armament- Second Year Advanced.
f. Air Force Communications - Second Year Advanced.
g. Statistical Control - Second Year Advanced.
h. Air Force Supply - Second Year Advanced.
i. Air Force Transportation - Second Year Advanced.

2. Air Force Commanders, Professors of Air Science and Tactics, Instructors and Assistant Instructors will examine this report and where necessary take corrective action and/or recognize superior performance with a view toward improving AFROTC training.

3. The major purposes of this and future evaluation reports is to reveal areas where proper performance levels are being maintained, to indicate the directions in which improvements should be made, and to afford essential facts for self directed development on the part of the instructor. It is the latter purpose which is the most important of all since its effective realization on the part of each instructor will influence the growth and development of future Air Force officers.

4. The preparation and administration of these examinations were accomplished through the cooperative efforts of all personnel involved in the AFROTC program. It is felt that through continued cooperative efforts the level of instruction will be improved and more effective evaluation techniques developed.

2-3311-11

0664

THIS PAGE IS DECLASSIFIED IAW EO 13526

5. This report will be brought to the attention of interested University officials, that is members of the civilian instructional staff interested in educational evaluation, the military coordinator, and each member of the AFROTC staff. Suggestions as to means by which future evaluation procedures and reports can be more helpful are solicited.

BY COMMAND OF MAJOR GENERAL WEBSTER:

J. H. BLOSS
Lt Col., AGD (USAF)
Asst Adj Gen

CHAPTER I

THE ROLE AND USES OF AIR-FORCE-WIDE COURSE EXAMINATIONS IN THE AIR ROTC PROGRAM

The Prime Mission

The elemental fact is that air-force-wide course examinations are directly and closely releated to the prime question, Are our Air Force ROTC schools achieving the objectives that they are supposed to reach? This major responsibility rests upon the shoulders of every instructor and every supervisor and they should be able to answer this question -- the teacher for his class -- and the supervisor for his school. In order to answer this question, it is necessary to assemble all the essential information and evaluate these facts with reference to the attainment of the goals of Air Force ROTC schools. This evaluation process is many-sided, continuous, and should include both subjective and objective ratings or measures. In this board evaluation process, testing through the use of achievement examinations occupies a coordinate and significant role, namely that of providing objective, valid and systematic evidence of the degree to which students are developing the facts, knowledges and understandings which should be the outcomes of coordinated and integrated instruction periods.

The air-force-wide achievement or course examinations are valid, reliable, and objective measuring instruments. These examinations have been designed for the purpose of revealing the student's general level of accomplishment and his proficiencies and deficiencies in his field of specialization, and for the purpose of providing the director and officer instructor a factual basis in terms of objective

THIS PAGE IS DECLASSIFIED IAW EO 13526

test results for changes in personnel, procedures and policies.

The evaluation of student achievement is not the task of any one person. The director, the Professor of Air Science and Tactics, and the school instructors are all involved and though they participate in the evaluation program in different roles, they receive benefits from it. In subsequent paragraphs some of the specific uses of achievement or course examinations by the instructor, supervisor and director will be listed. All members of the staff make use of the same basic data, but these data may be interpreted in different ways.

<u>How the Instructor Uses the Examination Results</u>

Fundamentally, effective instruction results largely from the contact of instructor and individual student, and therefore, the importance of the instructor's use of the tests is manifest. It is axiomatic that the more individualized the instruction, the better the quality and the greater the quantity of desired changes will be engendered in the student. This critical learning principle will yield sterile results unless the instructor knows the strength and weakness of the individual student and his class, and plans intelligently for his particular needs as far as is practical. Some of the ways in which the instructor may use test results and provide optimum conditions for the individualization of instruction are as follows:

1. To help determine the achievement level of each student in each course with relation to ability and experience.
2. To determine the average achievement level of a class at the end of the year.

0673

3. To compare present achievement with past achievement in order to determine the rate of progress.
4. To compare the achievement of his class with other classes and with the national or air-force-wide norm or standard.
5. To obtain a picture of the nature and range of individual differences in the group and make lesson plans with these considerations in mind.
6. To help diagnose an individual pupil's difficulties in learning.
7. To call attention to certain topics or sub-topics where more detailed testing is required to check on the effectiveness of instruction.
8. To provide a basis for counseling with the student's educational adviser regarding a pupil's achievement.
9. To provide one objective check on his own effectiveness.
10. To contribute an objective rating to the student's final course grade.
11. To serve as a motivating factor for the student.

These examinations can be used, therefore, to guide and motivate learning, to measure how much, how well, and how rapidly each student has progressed, to serve as a basis for the removal of individual difficulties, to help to evaluate the achievement of each student in terms of his ability and effort and to give the instructor one reading as to how well his instruction is received by his students.

THIS PAGE IS DECLASSIFIED IAW EO 13526

How the Professor of Air Science and Tactics Uses the Test Results

The Professor of Air Science and Tactics is also interested in the same kind of examination information as is the teacher. However, there are other aspects of the test which have particular interest for him as the administrative head of the school. Some of these other uses to which he may put the test results are as follows:

1. To determine the achievement level of each course group in a school.
2. To get an over-all picture of each course group in relation to each other course group.
3. To discover course specialization fields where test results are excellent, satisfactory, or poor.
4. To compare course test results from year to year and note improvement or regression.
5. To provide a continuing record of achievement in the school which will reflect changes in course content emphasis and in the characteristics of the student population,
6. To provide objective information on a student's avhievement for various administrative purposes.
7. To provide a basis for working with an individual instructor on methods of teaching and content of the course.

How The Administrative Personnel Uses the Test Results

1. To determine the achievement status of each school in each course in comparison with a national norm or average.
2. To evaluate the comparative achievements from course to course.

0675

3. To compare present achievement with past achievement in order to determine the rate of progress.
4. To compare the achievement of his class with other classes and with the national or air-force-wide norm or standard.
5. To obtain a picture of the nature and range of individual differences in the group and make lesson plans with these considerations in mind.
6. To help diagnose an individual pupil's difficulties in learning.
7. To call attention to certain topics or sub-topics where more detailed testing is required to check on the effectiveness of instruction.
8. To provide a basis for counseling with the student's educational adviser regarding a pupil's achievement.
9. To provide one objective check on his own effectiveness.
10. To contribute an objective rating to the student's final course grade.
11. To serve as a motivating factor for the student.

These examinations can be used, therefore, to guide and motivate learning, to measure how much, how well, and how rapidly each student has progressed, to serve as a basis for the removal of individual difficulties, to help to evaluate the achievement of each student in terms of his ability and effort and to give the instructor one reading as to how well his instruction is received by his students.

How the Professor of Air Science and Tactics Uses the Test Results

The Professor of Air Science and Tactics is also interested in the same kind of examination information as is the teacher. However, there are other aspects of the test which have particular interest for him as the administrative head of the school. Some of these other uses to which he may put the test results are as follows:

1. To determine the achievement level of each course group in a school.
2. To get an over-all picture of each course group in relation to each other course group.
3. To discover course specialization fields where test results are excellent, satisfactory, or poor.
4. To compare course test results from year to year and note improvement or regression.
5. To provide a continuing record of achievement in the school which will reflect changes in course content emphasis and in the characteristics of the student population.
6. To provide objective information on a student's avhievement for various administrative purposes.
7. To provide a basis for working with an individual instructor on methods of teaching and content of the course.

How The Administrative Personnel Uses the Test Results

1. To determine the achievement status of each school in each course in comparison with a national norm or average.
2. To evaluate the comparative achievements from course to course.

THIS PAGE IS DECLASSIFIED IAW EO 13526

3. To evaluate the comparative achievement from school to school in specified courses and with particular reference to administrative considerations such as time allotments, student load, quality and quantity of instructional materials, and particular school's policy and practice regarding Air Force ROTC courses.

4. To detect changes in the character of the student population over a period of years.

5. To determine those course fields in which further professional training of instructors is desirable.

6. To evaluate teaching and instructional materials.

7. To direct and control significant broad curricular emphasis.

8. To determine the possible need for curriculum changes.

9. To determine the minimum levels of achievement in specified specialization fields.

10. To provide an air-force-wide yardstick necessary for adequate and valid evaluations and comparisons.

The uses of examinations as listed above do not exhaust all the possibilities. Other uses could be listed.

An air-force-wide program of evaluating student progress contributes to the coordination of the various educational activities of the schools; first, through cooperative efforts to agree on common objectives and emphasis. Clearly defined standards or goals in terms of examination questions, determined co-operatively by all who participate in evaluating student achievement, bring about good working relationships.

A basic requirement in evaluation namely, that objectives be clearly defined, stated and eventually incorporated into significant thought-provoking examination questions helps the instructors to know what they are trying to appraise, what experiences to provide for students, and what evidence of growth they must look for in students.

In conclusion, therefore, the examination can be, and often is, an extremely important instrument. Every examination teaches both the instructor and student something. The examination affects their mental processes and attitudes.

Insofar as is humanly possible, the examination should be constructed not to train the students in memory processes only. On the other hand, questions should be phrased so that students are directed to relate facts, apply them to meaningful problems, develop principles and generalizations. Investigations show that the method of student preparation does differ with the characteristics of an examination. On the other hand, the results of studies also show that a method of studying which emphasized organization of material resulted in a better command of the subject as tested by four different types of examinations. Instead of emphasizing methods of storing up prospective answers for examinations, the students should be given practice in organizing, relating, and evaluating. In other words, instead of causing the thinking process to be narrowly confined, questions and examinations should stimulate critical thinking, get at understandings and fundamental concepts. If the instructor is willing to devise questions for examinations so that they stress judgment, evaluation, and original reactions many can succeed in so doing.

THIS PAGE IS DECLASSIFIED IAW EO 13526

CHAPTER II

ACHIEVEMENT OF AIR ROTC SCHOOLS ON THE ANNUAL COURSE EXAMINATIONS

The Air ROTC course examinations were administered to 8092 students in 112 colleges and universities throughout the United States. In all, there were eight course examinations utilized. Each course examination was composed of eighty (80) multiple choice (five alternatives) items covering the significant areas in the following course fields:

1. Administration and Military Management.
2. Aircraft Maintenance Engineering.
3. Armament.
4. Communications.
5. Introduction to USAF.
6. Statistical Control.
7. Supply.
8. Transportation.

These course examinations are achievement tests which cover the important facts, knowledges and understandings in each of the eight Air ROTC courses or job fields.

The number of schools taking each examination varied. The greatest number, 112 schools, took the Introduction to USAF examination; the smallest number of schools, seven (7), took the Armament examination.

All test scores were recomputed according to the formula:

> Test score equals the number of correct responses minus one-fourth (1/4) the number of wrong responses.

The results of each of the eight examinations reveal a wide range of student achievement as shown in the summary of the lowest and highest scores for each examination. The latter results and additional data are given below:

1949 Air ROTC Course Examination	Students Examined	No. of Schools	Lowest Score	Average Score	Highest Score	No. of Items
Administration & Military Management	1379	55	14	49	76	80
Aircraft Maintenance	497	30	21	55	78	80
Armament	154	7	13	53	76	80
Communications	225	19	10	52	80	80
Introduction to USAF	5043	112	0	49	79	80
Statistical Control	269	15	26	51	69	80
Supply	306	18	22	52	76	80
Transportation	219	12	23	48	78	80

The greatest range, from zero score to a score of 79, was that for the examination, Introduction to USAF. The examination with the smallest range is that for Statistical Control. In general, the test that can distribute the examinees over the wider range is the better test.

The mean or average scores of the eight tests range from 48 to 55. The Aircraft Maintenance examination with a mean score of 55, and the Transportation examination with a mean score of 48, were the highest and lowest means respectively. The mean scores on the examinations ranged from 48 to 55 and may indicate that the tests were not of equal difficulty. However, it is hazardous to make any conclusions as to the difficulty of the tests unless at least the mean mental ability of the various examination groups were approximately equal. No definite information on the latter point is available at present.

An analysis of the test results of the various schools was planned. A distribution of mean scores of all schools taking a specific examination was made. Table 1 presents the latter test results for all course examinations. The greatest number of schools taking a course examination was 112 (Introduction to USAF). The range of achievement on each of the examinations is very wide. For example, on the Transportation examination, one school of the twelve (12) which took the examination attained a mean score in the interval 72-74, while two of the twelve schools attained a mean score of 30. The range of achievement on the Statistical Control examination was the smallest, namely, mean scores from 36 to about 53.

TABLE 1

COMPOSITE DISTRIBUTION OF SCHOOL MEAN SCORES ON AIR ROTC COURSE EXAMINATIONS
1948-1949

No. of Items on Test	80	80	80	80	80	80	80	80
(School Mean (Score Interval	Intro. to USAF	Admr.& Mil.Mng.	A/C Main.	Armament	Comms.	Stat.Con.	Supply	Trans.
72-74			1		1			1
69-71			1		1			0
66-68	1	3	2	2	0			1
63-65	3	3	3	1	1		1	1
60-62	4	5	0	1	0		0	0
57-59	8	3	6	0	2	1	4	0
54-56	13	6	4	0	2	3	4	0
51-53	14	5	3	1	4	6	1	0
48-50	17	6	5	0	1	2	2	0
45-47	18	9	2	0	2	1	1	2
42-44	23	8	2	0	1	1	4	2

30-32	1	0	0	0	0	0	0	2
27-29	0	0	0	1	0	0	0	0
Totals	112	55	30	7	19	15	18	12

THIS PAGE IS DECLASSIFIED IAW EO 13526

The variability in the achievement of the various schools on each examination may be simply, though not too accurately, measured by comparing the schools with the lowest means and the schools with the highest means. In some cases, the schools with the lowest means achieved roughly on the average only half as much as the schools which returned the highest averages.

The crude quotients of the division of lowest school means by the highest school means for each of the eight examinations reveal the following results:

1. Administration and Military Management. The schools with the lowest means achieved roughly on the average only half as much as the schools which returned the highest averages.

2. Aircraft Maintenance Engineering. The schools with the lowest means achieved roughly on the average only half as much as the schools which returned the highest averages.

3. Armament. The school with the lowest average achieved roughly about forty percent as much as the schools with the highest averages.

4. Communications. The schools with the lowest means achieved roughly only half as much as the schools which returned the highest averages.

5. Introduction to USAF. The schools with the lowest means achieved roughly only half as much as the schools which returned the highest averages.

6. Statistical Control. The schools with the lowest means achieved roughly about 66 percent as much as the schools with the highest averages.

7. Supply. The schools with the lowest means achieved on a average about 66 percent as much as the schools which returned the highest averages.

8. Transportation. The schools with the lowest averages achieved roughly on the average about 45 percent as much as the schools which returned the highest averages.

A more detailed analysis of the test results for each of the eight (8) examinations is given in the immediate subsequent sections of this chapter.

0683

RESULTS ON AIR ROTC COURSE EXAMINATIONS - 1949

Results of Administration and Military Management Examination

The 80-item test on Administration and Military Management was administered to 1,379 students. The results by air force and for all air forces combined are given in Table 2.

TABLE 2

Results of Administration and Military Management Examination for 55 Schools

Air ROTC 1948 - 1949

	No. of Students	Mean	Raw Score Lowest	Raw Score Highest	Relative Rank of Air Force
First Air Force	171	56	23	76	1
Fourth Air Force	217	54	25	76	2
Ninth Air Force	257	50	20	73	4
Tenth Air Force	303	53	21	75	3
Twelfth Air Force	218	44	14	68	6
Fourteenth Air Force	213	45	16	68	5
All Air Forces	1,379	49	14	76	

The First Air Force, with an average score of 56, achieved the top rank.

A distribution was made of the mean scores of the 55 schools where the test was given. This distribution of scores is given below in Table 3.

TABLE 3

Distribution of School Averages and Selected Percentiles On the Administration and Military Management Examinations

46	40%
44	30%
42	20%
38	10%
33	1%

0684

The left half part of Table 3 shows that the school average scores range from a low of 33 to a high of 68. Of the 55 schools 37 or about 68% attained mean scores between 42 and 59. The schools with the lowest means achieved roughly on the average only half as much as the schools which returned the highest averages. There is evidently a very wide range in achievement among these schools.

As an aid in interpreting the school test results the distribution of school averages has been divided into percentiles. Percentiles are points in a distribution of scores below which lie a given percentage of the total number of schools. Eleven percentile points, P99, P90, P80, P70, P60, P50, P40, P30, P10 and P1 with their corresponding score values are given in the right hand part of Table 3. A school average of 68 was obtained by the top 1% of the 55 schools or stated in other words, 99% of the schools attained average scores below 68. An average score of 62 is the score at or below which lie 90% of the school averages; an average score of 57 is the score at or below which lie 80% of the school averages; an average score of 54 is the score at or below which lie 70% of the school averages. The other percentiles may be interpreted in a similar manner. P50 or the fiftieth percentile marks the mid-point of the distribution of school means, that is, it is the point below which fifty percent (50%) of the school averages lie and above which the other fifty percent (50%) lie. The great majority of the schools attained mean scores between thirty percentile points above P50, i.e., P80 and thirty percentile points below P50, e.e., P20. The range P20 to P80 includes the middle 60% of the school averages or stated in terms of score values the middle 60% of the school averages fell between 42 and 57. Schools attaining averages in the bottom 30%, i.e., P30, may find it highly desirable to institute changes in methods of instruction, to heighten student interest, and to provide adequate curricular materials. However in evaluating the achievement of the latter group of schools it is necessary to take into consideration the mental ability of the students concerned. See Chapter 6 for a better explanation.

Table 4 gives the mean scores and percentiles for each of the schools which took the examination in Administration and Military Management.

* Percentile ranks are points in a series of scores below which lie a given percentage of the total number of schools. A percentile rank of fifty (P50) means that the school attained a score below which approximately fifty per cent of the school mean scores lie and above which the other fifty per cent lie. A percentile rank of ninety (P90) indicates that approximately ninety per cent of the schools attained mean scores below this point, and that only ten per cent of the schools achieved scores above this point. Therefore, the 99th percentile is the highest or best percentile ranking and the 1st percentile is the lowest or poorest percentile ranking.

THIS PAGE IS DECLASSIFIED IAW EO 13526

Results of Aircraft Maintenance Engineering Examination

The 80-item test on Aircraft Maintenance Engineering was administered to 497 students. The results by air force and for all air forces combines are given in Table 5.

TABLE 5

Results of Aircraft Maintenance Engineering Examination for 30 Schools

Air ROTC 1948 - 1949

Air Force	No. of Students	Mean	Lowest	Highest	Relative Rank of Air Force
First Air Force	10	45	24	65	6
Fourth Air Force	89	50	21	72	4
Ninth Air Force	88	62	39	78	2
Tenth Air Force	126	54	27	74	3
Twelfth Air Force	113	48	23	74	3
Fourteenth Air Force	71	63	31	76	1
All Air Forces	497	55	21	78	

The Fourteenth Air Force, with an average score of 63, achieved the top rank.

A distribution was made of the mean scores of the 30 schools where the test was given. This distribution of scores is given below in Table 6.

TABLE 6

Distribution of School Averages and Selected Percentiles on the Aircraft Maintenance Engineering Examination

Distribution of Averages: School Average Scores	No.	Score Value of Percentiles: Average Score	Percentile
72-74	1	73	99%

33-35	1	33	1%
Total	30		

0688

The left half part of Table 6 shows that the school averages range from a low of 33 to a high of 74. Of the 30 schools 23 or about 77% attained means scores between 45 to 65. The schools with the lowest means achieved roughly on the average only half as much as the schools which returned the highest averages. Even though the number of participating schools are as few as thirty, nevertheless there is evidence of a great variation in achievement from school to school.

As an aid in interpreting the school test results the distribution of school averages has been divided into percentiles. Percentiles are points in a distribution of scores below which lie a given percentage of the total number of schools. Eleven percentile points, P99, P90, P80, P70, P60, P50, P40, P30, P20, P10 and P1 with their corresponding score values are given in the right hand side of Table 6. A school average of 73 was obtained by the top 1% of the 30 schools or stated in other words, 99% of the schools attained average scores below 73. An average score of 69 if the score at or below which lie 90% of the school averages; an average score of 64 is the score at or below which lie 80% of the school averages; an average score of 59 is the score at or below which lie 70% of the school averages. The other percentiles may be interpreted in a similar manner. P50 or the fiftieth percentile marks the mid-point of the distribution of school means, that is, it is the point below which 50% of the school averages like and above which the other fifty percent (50%) lie. The great majority of the schools attained mean scores between thirty percentile points below P50, i.e., P30, and thirty percentiles points below P50, i.e., P20. The range P20 to P80 includes the middle 60% of the school averages or stated in terms of score values the middle 60% of the school averages fell between 47 and 64. Schools attaining averages in the bottom 30%, i.e., P30, may find it highly desirable to institute changes in methods of instruction, to heighten student interest, and to provide adequate curricular materials. However in evaluating the achievement of the latter groups of schools it is necessary to take into consideration the mental ability of the students concerned. See Chapter 6 for a fuller explanation.

Table 7 gives the mean scores and percentiles for each of the schools which took the examination in Aircraft Maintenance.

Clemson Ag. Coll.	20	55	31	71	50

*Percentile ranks are points in a series of scores below which lie a given percentage of the total number of schools. A Percentile rank of fifty (P50) means that the school attained a score below which approximately fifty (P50) percent of the school mean scores lie and above which the other fifty percent lie. A percentile rank of ninety (P90) indicates that approximately ninety percent of the schools attained mean scores below this point, and that only ten percent of the schools achieved scores above this point. Therefore, the 99th percentile is the highest or best percentile ranking and the 1st percentile is the lowest or poorest percentile ranking.

Results of Armament Examination

The 80-item test on Armament was administered to 154 students in seven (7) schools. The mean score attained by these students from all participating air forces was 53. No comparison by separate air forces was made because the number of schools represented in each of the air forces were too few. However, adistribution of the mean scores of the seven (7) schools was made and the tabulation is given in Table 8.

TABLE 8

Distribution of School Averages and Estimated Percentiles on the Armament Examination for 7 Schools

Air ROTC 1948 - 1949

33-35	0		
30-32	0		
27-29	1	27	1%
TOTAL	7		

* Percentiles given here are very rough estimates.

The left half part of Table 8 shows that the school averages range from a low of 27 to a high of 68. The school with the lowest mean achieved roughly on the average about forty per cent (40%) as much as the schools which returned the highest averages. There is a wide variation in achievement from school to school. As an aid in interpreting the school test results the distribution of school averages has been divided into percentiles. Percentiles are points in a distribution of scores below which lie a given percentage of the total number of schools. Five percentile points, P99, P80, P50, P20 and P1 with their corresponding score values are given in the right-hand part of Table 8. These percentiles, because of the very few cases involved, are very rough estimates and have been interpolated so that certain inter-test comparisons can be made later. With this limitation in mind an explanation of the meaning of these percentiles will be given. A school average of 68 was achieved by the top 1 per cent of the 7 schools or stated in other words, 99 per cent of the schools attained average scores below 68. An average score of 65 is estimated to be the score at or below which lie 80 per cent of the school averages. P50, i.e., the fiftieth percentile roughly marks the mid-point of the distribution of school means, that is, it is the point below which roughly fifty per cent (50%) of the school averages lie and above which the other fifty per cent (50%) of the school averages lie and above which the other fifty percent (50%) lie. An average score of 41 is the score at or below which lie 20 per cent of the school averages, an average score of 27 is the score at or below which lie 1 per cent of the school averages. Schools attaining average scores in the bottom thirty per cent, i.e., P30 or average scores below 44 may find it highly desirable to institute changes in methods of instruction, to heighten student interest, and to provide adequate curricular material. However, in evaluating the achievement of the latter group of schools it is necessary to take into consideration the mental ability of the students concerned. See Chapter 6 for a fuller explanation.

Table 9 gives the mean scores and percentiles for each of the schools which took the examination in Armament.

TABLE 9

Means and Percentile Ranks of Seven Air ROTC Schools Which Took The Armament Examination

Air ROTC 1948-49

Schools	No. of Students Examined	RAW SCORE (Possible 80) Mean	Lowest	Highest	*Percentile Rank of 7 Schools

NINTH AIR FORCE	23				
Georgetown University	23	28	13	43	1
TENTH AIR FORCE	43	59	41	76	
University of Kansas	20	51	41	71	40
University of Missouri	23	67	49	76	93

TABLE 9 - Armament Exam (Continued)

Schools	No. of Students Examined	RAW SCORE (Possible 80) Mean	Lowest	Highest	*Percentile Rank of 7 Schools
TWELFTH AIR FORCE	26				
Texas Tech College	26	40	24	54	19
FOURTEENTH AIR FORCE	34	61	49	72	
Mississippi State College	25	60	49	68	68
University of Tennessee	9	64	53	72	77

* Percentile ranks are points in a series of scores below which lie a given percentage of the total number of schools. A percentile rank of fifty (P50) means that the school attained a score below which approximately fifty percent of the school mean scores **lie** and above which the other fifty percent lie. A percentile of ninety (P90) indicates that approximately ninety percent of the schools attained mean scores below this point, and that only ten percent of the schools achieved scores above this point. Therefore, the 99th percentile is the highest or best percentile ranking and the 1st percentile is the lowest or poorest percentile ranking.

Because of the small number of schools involved, the percentile rankings are best estimated values.

Results of Communications Examination

The 80-item test on Communications was administered to 225 students. No comparison by air force was made because the number of schools represented in each air force were too few. However, a distribution of the mean scores of the 19 participating schools was made and the tabulation is given in Table 10.

TABLE 10

Distribution of School Averages and Selected Percentiles on the Communications Examination for 19 Schools

Air ROTC 1948-1949

Distribution of Averages: School Average Scores	No. of Schools	Score Value of Percentiles *: Average Score	Percentile
72-74	1	72	99%
69-71	1	69	90%
66-68	0		
63-65	1		

0693

THIS PAGE IS DECLASSIFIED IAW EO 13526

TABLE 10 - Communications Exam (Continued)

Distribution of Averages		Score Value of Percentiles *	
School Average Scores	No. of Schools	Average Score	Percentile
60-62	0	61	80%
57-59	2	59	70%
54-56	2	54	60%
51-53	4	52	50%
48-50	1	49	40%
45-47	2	47	30%
42-44	1		
39-41	2	41	20%
36-38	2	38	10%
33-35	0	36	1%
Total	19		

* Percentiles given here are rough estimates.

The left half part of Table 10 shows that the school averages range from a low of 36 to a high of 74. Of the 19 schools 12 or 63% attained mean scores between 42 and 62. The schools with the lowest means achieved roughly on the average only half as much as the schools which returned the highest averages. There is evidently a very wide range in achievement among these schools.

As an aid in interpreting the school test results the distribution of school averages has been divided into percentiles. Percentiles are points in a distribution of scores below which lie a given percentage of the total number of schools. Eleven percentile points, P99, P90, P80, P70, P60, P50, P40, P30, P10 and P1 with their corresponding score values are given in the right hand part of Table 10. A school average of 72 was obtained by the top 1% of the 55 schools or stated in other words, 99% of the schools attained average scores below 72. An average score of 69 is the score at or below which lie 90% of the school averages; an average score of 61 is the score at or below which lie 80% of the school averages; an average score of 59 is the score at or below which lie 70% of the school averages. The other percentiles may be interpreted in a similar manner. P50, i.e., the fiftieth percentile marks the mid-point of the distribution of school means, that is, it is the point below which 50% of the school averages lie and above which the other 50% lie. The great majority of the schools attained mean scores between thirty percentile points above P50, i.e., P80 and thirty percentile points below P50, i.e., P20. The range P20 to P80 includes the middle 60% of the school averages or stated in terms of score values the middle 60% of the school averages fell between 41 and 61. Schools attaining averages in the bottom 30%, i.e., P30, may find it highly desirable to institute

0694

Air Force	No. of Students	Raw Score Mean	Raw Score Lowest	Raw Score Highest	Relative Rank of Air Forces
First Air Force	578	52	21	79	1
Fourth Air Force	806	49	0	75	3
Ninth Air Force	841	50	15	79	2
Tenth Air Force	1405	48	14	78	4.5
Twelfth Air Force	725	46	17	68	6
Fourteenth Air Force	687	48	4	75	4.5
All Air Forces	5043	49	0	79	

The First Air Force with an average score of 52 achieved the top rank.

A distribution was made of the mean scores of the 112 schools where the course examination was given. This distribution of scores is given below in Table 13:

0697

THIS PAGE IS DECLASSIFIED IAW EO 13526

TABLE 13

Distribution of School Averages and Selected Percentiles on the Introduction to USAF Examination

Distribution of Averages		Score Value of Percentiles	
School Average Scores	No.	Average Score	Percentile
66-68	1	66	99%
63-65	3		
60-62	4		
57-59	8	57	90%
54-56	13	54	80%
51-53	14	52	70%
		50	60%
48-50	17	48	50%
45-47	18	46	40%
42-44	23	44	30%
		42	20%
39-41	5	41	10%
36-38	5		
33-35	0		
30-32	1	31	1%
Total	112		

The left half part of Table 13 shows that the school averages range from a low of 30 to a high of 68. Of the 112 schools 85 or about seventy-six percent (76%) attained mean scores between 42 and 56. The schools with the lowest means achieved roughly on the average only half as much as the schools which returned the highest averages. There is great variation in achievement among the schools, due principally to such factors as student ability and motivation, teacher personality, methods of instruction and adequacy of instructional materials.

0698

As an aid in interpreting the school test results the distribution of school averages has been divided into percentiles. Percentiles are points in a distribution of scores below which lie a given percentage of the total number of schools. Eleven percentile points, P99, P90, P80, P70, P60, P50, P40, P30, P20, P10 and P1 with their corresponding score values are given in the right hand part of Table 13. A school average of 66 was obtained by the top 1 percent of the 112 schools or stated in other words, 99% of the schools attained average scores below 66. An average score of 57 is the score at or below which lie 90% of the school averages; an average score of 54 is the score at or below which lie 80% of the school averages; an average score of 52 is the score at or below which lie 70% of the school averages. The other percentiles may be interpreted in a similar manner. P50, or the fiftieth percentile marks the mid-point of the distribution of school means, that is, it is the point below which fifty percent (50%) of the school averages lie and above which the other fifty percent (50%) lie. The great majority of the schools attained mean scores between thirty percentile points above P50, i.e., P80, and thirty percentile points below P50, i.e., P20. The range P20 to P80 includes the middle sixty per cent (60%) of the school averages or stated in terms of score values the middle sixty percent (60%) of the school averages fell between 44 to 54. Schools attaining averages in the bottom thirty per cent, i.e. P30, may find it highly desirable to institute changes in methods of instruction to heighten student interest, and to provide adequate curricular materials. However, in evaluating the achievement of the latter group of schools it is necessary to take into consideration the metal ability of the students concerned. See Chapter VI for a fuller explanation.

Table 14 gives the results on the Introduction to USAF examination.

TABLE 14

MEANS AND PERCENTILE RANKS OF AIR ROTC SCHOOLS
WHICH TOOK THE INTRODUCTION TO USAF EXAMINATION

AIR ROTC 1948-49

Schools	No. of Students Examined	RAW SCORE (Possible 80)			*Percentile Ranks of 112 Schools
		Mean	Lowest	Highest	
ALL AIR FORCES	5043	49	0	79	
FIRST AIR FORCE	578	52	21	79

New York University	41	65	48	79	98
Syracuse University	50	50	30	69	60

*Percentile ranks are points in a series of scores below which lie a given percentage of the total number of schools. A percentile rank of fifty (P_{50}) means that the school attained a score below which approximately fifty per cent of the school mean scores lie and above which the other fifty per cent lie a percentile rank of ninety P_{90}) indicates that approximately ninety per cent of the schools attained mean scores below this point and that only ten per cent of the schools achieved scores above this point. Therefore, the 99th percentile is the highest or best percentile ranking and the 1st percentile is the lowest or poorest percentile ranking.

Therefore, the 99th percentile is the highest or best percentile ranking and the 1st percentile is the lowest or poorest percentile ranking.

Results of Statistical Control Examination

The 80-item test on Statistical Control was administered to 269 students in 15 schools. The mean score attained by these students from all participating air forces was 51. No comparison by separate air forces was made because the number of schools represented in each of the air forces were too few. However, a distribution of the mean scores of the 15 schools was made and the tabulation is presented in Table 15.

TABLE 15
Distribution of School Averages and Selected Percentiles on the Statistical Control Examination for 15 Schools.

Distribution of Averages		Score Value of Percentiles*	
School Average Scores	No.	Average Score	Percentile
57-59	1	59	99%
54-56	3	54	80%
51-53	6	52	50%
48-50	2		
45-47	1	47	20%
42-44	1		
39-41	0		
36-38	1	38	1%
Total	15		

*Percentiles given here are rough estimates.

The left half part of Table 15 shows that the schol averages range from a low of 36 to a high of 59. Of the 15 schools 9 or 60% attained mean scores between 45 and 53. The schools with the lowest means achieved roughly on the average about two thirds as much as the schools which returned the highest averages. There is nevertheless a wide range in achievement among these schools.

0706

THIS PAGE IS DECLASSIFIED IAW EO 13526

As an aid in interpreting the school test results the distribution of school averages has been divided into percentiles. Percentiles are points in a distribution of scores below which lie a given percentage of the total number of schools. Five percentile points, P99, P80, P50, P20, P1 with their corresponding score values are given in the right hand part of Table 15. A school average of 59 was achieved by the top 1% of the 15 schools or stated in other words, 99% of the schools attained average scores below 59. An average score of 54 is the score at or below which lie 80% of the school averages. P50, i.e., the fiftieth percentile marks the mid-point of the distribution of school means, that is, it is the point below which roughly 50% of the school averages lie and above which the other 50% lie. An average score of 47 is the score at or below which lie 20% of the school averages, an average score of 38 is the score at or below which lie 1% of the school averages. The majority of the schools attained mean scores between P20 and P80. The range P20-P80 includes the middle 60% of the school averages or stated in terms of score values, the middle 60% of the school averages fell between 47 and 54. Schools attaining averages in the bottom 30%, i.e., P30 or average scores of 49 or below may find it highly desirable to institute changes in methods of instruction, to heighten student interest, and to provide adequate curricular materials. However, in evaluating the achievement of the latter group of schools it is necessary to take into consideration the mental ability of the students concerned. See Chapter 6 for a fuller explanation.

Table 16 gives the mean scores and percentiles for each of the schools which took the examination in Statistical Control.

TABLE 16

Means and Percentile Ranks of Air ROTC Schools Which Took the Statistical Control Examination

42-44	4	44	20%
		43	10%
39-41	1	40	1%
Total	18		

*Percentiles given here are rough estimates.

The left half part of Table 17 shows that the school averages range from a low average score of 39 to a high of 65. Of the 18 schools, 12 or 67% attained mean scores between 45 and 59. The schools with the lowest means achieved roughly on the average about two thirds as much as the schools which returned the highest averages. There is a wide range in achievement among these schools.

THIS PAGE IS DECLASSIFIED IAW EO 13526

As an aid in interpreting the school test results the distribution of school averages has been divided into percentiles. Percentiles are points in a distribution of scores below which lie a given percentage of the total number of schools. Eleven percentile points, P99, P90, P80, P70, P60, P50, P40, P30, P10 and P1, with their corresponding score values are given in the right hand part of Table 17. A school average of 64 was achieved by the top 1% of the 18 schools or stated in other words, 99% of the schools attained average scores below 64. An average score of 59 is the score at or below which lie 90% of the school averages; an average score of 57 is the score at or below which lie 80% of the school averages; an average score of 55 is the score at or below which lie 70% of the school averages. The other percentiles may be interpreted in a similar manner. P50, i.e., the fiftieth percentile marks the mid-point of the distribution of school means, that is, it is the point below which 50% of the school averages lie and above which the other 50% lie. The great majority of the schools attained mean scores between thirty percentile points above P50, i.e., P80; and thirty percentile points below P50, i.e., P20. The range P20 to P80 includes the middle 60% of the school averages or stated in terms of score values, the middle 60% of the school averages fell between 44 and 57. Schools attaining averages in the bottom 30%, i.e., P30 may find it highly desirable to institute changes in methods of instruction, to heighten student interest, and to provide adequate curricular material. However, in evaluating the achievement of the latter group of schools, it is necessary to take into consideration the mental ability of the students concerned. See Chapter 6 for a fuller explanation.

Table 18 gives the mean scores and percentiles for each of the schools which took the examination in Supply.

Table 18

Means and Percentile Ranks of Air ROTC Schools Which Took the Supply Examination

University of Minnesota	22	46	22	61	30
University of Wisconsin	6	44	31	61	20
TWELFTH AIR FORCE	23				
New Mexico Colg. A&MA	23	40	30	48	1
FOURTEENTH AIR FORCE	64	54	33	71	
University of Florida	21	59	50	71	90
University of Mississippi	13	42	33	59	7
The Citadel	30	56	33	71	75

*Percentile ranks are points in a series of scores below which lie a given percentage of the total number of schools. A percentile rank of 50 (P50) means that the school attained a score below which approximately 50% of the school mean scores lie and above which the other 50% lie. A percentile rank of 90 (P90) indicates that approximately 90% of the schools attained mean scores below this point and that only 10% of the schools achieved scores above this point. Therefore the 99th percentile is the highest or best percentile ranking and the first percentile is the lowest or poorest percentile ranking.

Because of the small number of schools involved the percentile rankings are best estimated values.

0712

Results of Transportation Examination

The 80-item test on Transportation was administered to 219 students in 12 schools. The mean score attained by these students from all participating air forces was 48. No comparison by separate air forces was made because the number of schools represented in each of the air forces were too few. However, a distribution of the mean scores of the 12 schools was made and the tabulation is given in Table 19.

Table 19

Distribution of School Averages and Selected Percentiles on the Transportation Examination for 12 Schools

Air ROTC 1948-1949

Distribution of Averages		Score Value of Percentiles*	
School Average Scores	No.	Average Score	Percentile
72-74	1	72	99%
69-71	0		
66-68	1		
63-65	1		
60-62	0		
57-59	0	57	80%
54-56	0		
51-53	0		
48-50	0		
45-47	2	47	50%
42-44	2		
39-41	1		
36-38	2	36	20%
33-35	0		
30-32	2	30	1%
Total	12		

*Percentiles given here are rough estimates.

The left half part of Table 19 shows that the school averages range from a low of 30 to a high of 74. Of the 12 schools, 7 or about 58 per cent attained mean scores between 36 and 47. The schools with the lowest means achieved roughly on the average about 45 per cent as much as the schools which returned the highest averages. The range of school achievement is greatest on the Transportation examination.

As an aid in interpreting the school test results the distribution of school averages has been divided into percentiles. Percentiles are points in the distribution of scores below which lie a given percentage of the total number of schools. Five percentile points; P99, P80, P50, P20 and P1 with their corresponding score values are given in the right hand part of Table 19. A school average of 72 was achieved by the top one percent (1%) of the 12 schools or stated in other words, 99% of the schools attained average scores below 72. An average score of 57 is the score at or below which lie 80% of the school averages. P50, i.e., the fiftieth percentile marks the mid-point of the distribution of school means, that is, it is the point below which roughly fifty per cent (50%) of the school averages lie and above which the other fifty per cent (50%) lie. An average score of 36 is the score at or below which lie 20% of the school averages; an average score of 38 is the score at or below which lie 1 per cent of the school averages. The majority of the schools attained mean scores between P20 and P80. The range P20-P80 includes the middle sixty per cent (60%) of the school averages or stated in terms of score values the middle sixty per cent (60%) of the school averages fell between 36 and 57. Schools attaining averages in the bottom thirty per cent (30%) i.e., P30 or average scores of 38 or below may find it highly desirable to institute changes in methods of instruction, to heighten student interest, and to provide adequate curricular methods. However, in evaluating the achievement of the latter group of schools, it is necessary to take into consideration the mental ability of the students concerned. See Chapter 6 for a fuller explanation.

Table 20 gives the mean scores and percentiles for each of the schools which took the examination in Transportation.

Table 20

Means and Percentile Ranks of Air ROTC Schools Which Took the Transportation Examination

Air ROTC 1948-1949

Schools	No. of Students Examined	RAW SCORE (Possible 80) Mean	Lowest	Highest	Percentile Ranks of 12 Schools
ALL AIR FORCES	219	48	23	78	
FIRST AIR FORCE	28	56	33	75	
University of Massachusetts	15	67	56	75	92
Syracuse University	13	43	33	50	41
FOURTH AIR FORCE	42	37	23	55

Coe College	15	36	27	50	20
South Dakota State College	9	72	65	78	99
TWELFTH AIR FORCE	35				
University of Arkansas	35	47	33	61	50
FOURTEENTH AIR FORCE	57	58	30	78	
Tuskegee Institute	39	64	38	78	85
Clemson Agricultural College	18	45	30	65	47

*Percentile ranks are points in a series of scores below which lie a given percentage of the total number of schools. A percentile rank of 50 (P50) means that the school attained a score below which approximately 50% of the school mean scores lie and above which the other 50% lie. A percentile rank of 90 (P90) indicates that approximately 90% of the schools attained mean scores below this point and that only 10% of the schools achieved scores above this point. Therefore the 99th percentile is the highest or best percentile ranking and the first percentile is the lowest or poorest percentile ranking.

Because of the small number of schools involved the percentile rankings are best estimated values.

0715

CHAPTER III

COMPARISON OF RANK ORDERS OF AIR ROTC SCHOOLS ON EIGHT COURSE EXAMINATIONS IN 1947-1948 and 1948-1949

This short section will deal with the question, To what degree do Air ROTC schools maintain their rank order of merit from 1947-1948 course examination to the 1948-1949 course examination? Based on the results of each course examination each school was placed in a rank order of merit, that is, the school with the highest mean score was given a rank of one (1), the school with the second highest score was given a rank of two (2), and so on. In order to make a valid comparison of the rank orders on any one course examination the schools which took the examination in 1947-48 must be compared with the same set of schools which took a similar examination in 1948-1949. Therefore, schools which took a course examination in 1947-1948 but did not take a similar course examination in 1948-1949 and schools which took the course examination in 1948-1949 but were not in the program to take a similar examination in 1947-1948 were not included in this comparison.

Differences among the schools were expressed by ranking the schools in one-two-three order. If the schools in 1947-1948 tend to maintain the same ranks in 1948-1949 then the correlation, that is, the relationship between the two sets of annual ranks is positive. If the schools in 1947-1948 reverse their rank order, that is, the schools that ranked near the top in 1947-1948 tended to rank toward the bottom and vice versa then the correlation is negative. The degree of correlation between two sets of measures can be indicated by coefficients. These coefficients of correlation may range from

THIS PAGE IS DECLASSIFIED IAW EO 13526

+ 1.00 to 0 to -1.00. It is customary to describe the correlation between two ranks or measures as high, marked or substantial, low or negligible. Coefficients of correlation between -.20 to 0 to + .20 denote negligible relationship, between + .21 to + .40 denote low or slight relationship, between + .41 to + .70 denote substantial relationship, between + .71 to + 1.00 denote close to very high relationship. Negative coefficients of correlation between -.21 to -.40, -.41 to -.70 and -.71 to -1.00 indicate corresponding degrees of inverse relationship.

The coefficients of correlations which will be presented have been calculated from a few cases and are, therefore, not very reliable; however, their chief value lies in suggesting the possible presence of relationship, as in a preliminary survey.

In all eight coefficients of correlations were computed, that is, one for each pair of annual ranks for each of the eight course examinations. The correlations range from substantial positive degree of relationship to a low or negligible relationship. None of the correlations were negative although some approached zero or no relationship at all. The coefficients of correlation between school ranks on 1947-1948 examination with the school ranks on the 1948-1949 examination in each course are as follows:

	COURSE EXAMINATION	COEFFICIENT OF CORRELATION	INTERPRETATION
1.	Armament	+ .70	Close positive relationship.
2.	Introduction to USAF	+ .50	Substantial positive relationship.

COURSE EXAMINATION	COEFFICIENT OF CORRELATION	INTERPRETATION
3. Administration and Military Management	+ .35	Slight positive relationship.
4. Communications	+ .33	Slight positive relationship.
5. Supply	+ .28	Slight positive relationship.
6. Statistical Control	+ .22	Slight positive relationship.
7. Aircraft Maintenance	+ .16	Negligible positive relationship.
8. Transportation	+ .06	Negligible positive relationship.

The course examinations where the highest positive correlations were obtained were Armament, Introduction to USAF and Administration and Military Management. On the latter examinations there was a tendency for schools to maintain their status rankings from 1947-1948 to 1948-1949. The three course examinations where the coefficients were lowest were Aircraft Maintenance, Statistical Control and Transportation. On the latter three examinations, therefore, there was a tendency for the schools to change their status ranks, that is, those that were high on the 1947-1948 examination were low on the 1948-1949 examination and vice versa.

These changes may be due to several factors; changes in effectiveness of course instruction, changes in student motivation, changes in course content, changes in instructor personnel and changes in the quality of mental ability of the student population. Changes in the difficulty of the two annual examinations in a subject field would not affect too greatly the inter-school comparisons because the examinations would be equally difficult or easy for both annual

0718

groups of schools and, therefore, would have little effect on the relative positions or rank orders of the schools concerned.

Tables 21 to 28 present the comparisons of rank orders of Air ROTC Schools on 1947-1948 and 1948-1949 examinations in each of the eight course fields.

CHAPTER IV

ANALYSIS OF TEST ITEMS ON THE ANNUAL AIR ROTC COURSE EXAMINATIONS

General Summary

Each of the eight course examinations contained eighty items. The performance of each item was carefully scrutinized. Each item was analyzed for two important aspects, validity and difficulty. Item validity is concerned with the ability of the item to differentiate between good students and poor students. Good students are students who do well in the course examination, and poor students are those who do poorly in the examination. Good discriminating power is indicated by positive validity coefficients. Validity coefficients may range from -1.00 to 0 to +1.00. A valid test of the type under consideration should contain items whose validity coefficients are close to .25 or better.

A summary of the item validities and the item difficulties are given in subsequent tables. Table 29 gives the distribution of item validities for each of the eight course examinations. The item validities were distributed into five categories after being rated as follows:

Validity coefficients .14 and below were rated poor;
Validity coefficients .15 to .24 were rated fair;
Validity coefficients .25 to .34 were rated good;
Validity coefficients .35 to .44 were rated very good;
Validity coefficients .45 and above were rated excellent.

THIS PAGE IS DECLASSIFIED IAW EO 13526

Table 29

Validity Coefficients of the Eighty Items on Each of the Eight Air ROTC Course Examinations Rated on a Five Category Basis

Course Examination	Percentage of Items in Each of the Five Categories: Excellent	Very Good	Good	Fair	Poor
Administration and Military Management	36%	29%	21%	10%	4%
Aircraft Maintenance Engineering	16%	25%	29%	21%	9%
Armament	51%	22%	13%	10%	4%
Communications	25%	31%	20%	14%	10%
Introduction to USAF	60%	23%	12%	4%	1%
Statistical Control	2%	14%	29%	34%	21%
Supply	19%	17%	24%	28%	12%
Transportation	48%	15%	16%	11%	10%

The course examination with the highest percent of excellent items and the one with the lowest per cent of poor items were Introduction to USAF and Armament respectively. The course examination with the lowest per cent of excellent items and the highest per cent of poor items is that in Statistical Control.

A briefer method of comparing the respective examinations from the point of view of validity coefficients is to calculate the per cent of items that reached the standard of .25 or better. This comparison is given below:

Air ROTC Course Examination	Percentage of Test Items Which Met the Standard of .25 or Better
Administration and Military Management	86%
Aircraft Maintenance Engineering	70%
Armament	86%
Communications	76%
Introduction to USAF	95%
Statistical Control	45%
Supply	89%
Transportation	79%

THIS PAGE IS DECLASSIFIED IAW EO 13526

The three examinations having the highest per cent of items meeting the standard of .25 or better are Introduction to USAF, Armament and Administration and Military Management. Introduction to USAF had the highest percentage, namely, 95 per cent. Of the eight examinations, all except that on Statistical Control meet acceptable standards from the point of view of item validity.

How do the item validities of the examinations of 1947-1948 compare with those of 1948-1949? A short method to use for comparing tests as to item validities is to compare the average of the eighty item validities. Table 30 presents the data essential for comparing the item validities over the past two years.

Table 30

Comparison of Average Item Validity Coefficients of Each Course Air ROTC Examination for Years 1947-1948 and 1948-1949

Course Examination	Average Item Validity Coefficient, 1947-48	Average Item Validity Coefficient, 1948-49
Administration and Military Management	.31	.40
Aircraft Maintenance	.29	.32
Armament	.22	.45
Communications	.31	.35
Introduction to USAF	.44	.45
Statistical Control	.26	.23
Supply	.29	.31
Transportation	.25	.40

All course examinations except that in Statistical Control show improvement in average item validity. The course examination in

0734

Introduction to USAF ranked first in both years. As a group, the 1948-1949 examinations show a very high order of merit in the matter of overall item validity.

Item Difficulty

Each test item was analyzed for its difficulty, that is, the number or per cent of the students who were able to answer the item correctly. Theoretically, in a good test there should be a proper proportion of easy, average and difficult items so that the average per cent difficulty of all the items in a test would be about fifty (50) per cent. However, in practice for most scholastic course examinations, an acceptable average per cent difficulty would be in the neighborhood of 60 to 65 per cent. Under certain circumstances the average per cent difficulty may be raised to 70 percent.

The analysis of the items as to validity coefficients is an important one to make for the instructor as an examiner. However, an analysis of the items from the point of view of the instructor as a teacher is one that tells how the items were passed or failed by the students on an Air-Force-wide basis.

The following tabular arrangement groups the items of each examination into ten categories of item-difficulty or item-pass percentages. For example, the number of items on the Administration and Military Management examination passed by 91% to 100% of the students tested was eight (8). Table 31 shows the distribution of the item-difficulty percents for all eight-course examinations.

0735

Table 31

Number of Items in Specified Student Pass-Per Cent Intervals for Each Air ROTC Course Examination

Course Examination	Item-Difficulty Per Cents Grouped in Ten Per Cent Interva									
	100% to 91%	90% to 81%	80% to 71%	70% to 61%	60% to 51%	50% to 41%	40% to 31%	30% to 21%	20% to 11%	10% or Less
Administration and Military Management	8	15	15	21	11	6	4	0	0	0
Aircraft Maintenance	9	20	21	14	7	3	4	1	0	0
Armament	12	16	17	20	9	4	1	1	0	0
Communications	7	15	23	15	8	10	1	1	0	0
Introduction to USAF	6	11	21	20	8	7	1	5	1	0
Statistical Control	10	14	20	15	12	5	3	0	1	0
Supply	8	25	13	10	10	11	3	0	0	0
Transportation	3	21	14	16	15	5	5	1	0	0

Table 31 reveals that all examinations showed a deficiency of item-difficulty per cents in the intervals from 30 per cent and below. The bulk of the item-difficulty per cents were in the itervals between 61% to 90% There are too many items appearing in the interval 100% to 91% difficulty; in other words, there are too many easy items included on all the examinations except, perhaps, the test on Transportation. Of the eight examinations, that for Introduction to USAF shows a fairly good dispersion and allotment of item-difficulties.

How difficult or how easy were the examinations of 1948-1949 as compared with those of 1947-1948? The data presented in Table 32 helps to answer this question. The average of all the pass-per cents on each examination was obtained. The average per cent difficulty is the average

THIS PAGE IS DECLASSIFIED IAW EO 13526

of the pass-per cents of the eighty items composing the examinations. Table 32 gives the average per cent difficulty of each examination for the years 1947-1948 and 1948-1949.

Table 32

Comparison of Average Per Cent Difficulty
For Eight Air ROTC Course Examinations For
Years 1947-1948 and 1948-1949

Course Examination	Average Per Cent Difficulty 1947-1948	Average Per Cent Difficulty 1948-1949
Administration and Military Management	64%	70%
Aircraft Maintenance	64%	73%
Armament	67%	72%
Communications	63%	71%
Introduction to USAF	58%	67%
Statistical Control	68%	70%
Supply	57%	71%
Transportation	68%	68%
Average of 8 Examinations	63.6%	70.2%

In all eight examinations the average per cent difficulty for 1948-1949 was equal or higher than those for 1947-1948. The average of the eight average per cent difficulties for 1947-1948 was 63.6%, while the average of the eight average difficulties for 1948-1949 was 70.2%. It is felt that for this type of annual examination, and in view of the purposes for which it is anticipated that it will be put, the average difficulty should not go beyond 65 to 70 per cent.

Subsequent sections of this chapter present a detailed analysis of the worth and value of items in each of the course examinations. Instructors should give close study to the section pertaining to their course field. Among other uses for which the detailed analysis of the performance of the test items will serve, the instructor should plan to review the item data with a view toward obtaining a deeper insight into the manner in which test items behave and thus improve his skill in constructing future examinations.

Administration and Military Management Examination

This examination consisted of eighty (80) multiple-choice items designed to measure student understanding of administrative practices and military management. A sample of four hundred (400) student papers were separated into five (5) ability groups, using total score as the criterion.

Test items were analyzed for their discriminating power, that is, their power to differentiate good students from poor students. Good discriminating power is indicated by positive validity coefficients and poor discriminating power is indicated by negative validity coefficients. Validity coefficients may range from -1.00 to 0 to +1.00. A valid test should contain items whose validity coefficients are at least .25 or better. Sixty-nine (69) of the eighty (80) items measured up to the standard of .25 or better for a discriminating item. The average validity coefficient for all test items was .40 compared with an index of .31 for a similar test which was administered last year. This represents a definite improvement in the discriminating power of the test.

This year's test items had an average difficulty of seventy per cent (70%) correct. They were slightly easier than test items (average difficulty 64% correct) of a similar test which was administered a year ago. The average per cent difficulty is the average of the pass-per cents of the eighty (80) items. The number of items of a specified difficulty is as follows:

	Difficulty (Per cent right)			
	50% and Below	51% to 90%	91% to 100%	Total Test
Number of items	10	62	8	80

A number of items are cited in which all incorrect alternatives were serving as effective distractors: 2, 3, 5, 7, 8, 9, 12, 16, 18, 21, 23, 24, 25, 27, 30 through 36, 38, 41, 44 through 50, 52, 54 through 56, 59 through 61, 63 through 66, 68, 73, 77, 78 and 80. The analysis of test items shows ineffective alternatives which might well be replaced by more plausible distractors. The alternatives listed below should be replaced, as they were chosen more frequently by good students than by poor ones:

Item	Alternative
4	A
37	D
42	B
51	C
53	D
57	B, E
58	C

In order to obtain a quick overview as to which items were excellent, very good, good, fair and poor, a distribution of eighty (80) items according to the degree of validity coefficient was made and given in Table 33.

Table 33

Validity Coefficients of the Eighty Items on the Administration and Military Management Examination

Coefficients .14 and below (Poor)	Coefficients .15 to .24 (Fair)	Coefficients .25 to .34 (Good)	Coefficients .35 to .44 (Very Good)		Coefficients .45 and above (Excellent)	
Item No.	Item No.	Item No.	Item No.		Item No.	
10	13	4	3	37	1	42
17	15	14	5	43	2	46
39	19	25	6	44	8	48
	26	27	7	45	9	50
	51	28	11	52	12	53
	69	29	20	54	16	55
	70	36	21	56	18	59
	71	40	22	58	30	63
		47	23	61	31	64
		49	24	77	32	68
		60	34		33	72
		62			35	76
		65			38	78
		66			41	79
		67				
		74				
		80				

The number and per cent of the items in each of the five (5) categories is as follows:

Category	Number of Items	Percent of Total (80)
Excellent	29	36%
Very Good	23	29%
Good	17	21%
Fair	8	10%
Poor	3	4%

About thirty-six per cent (36%) of the items are excellent; in all about eighty-six per cent (86%) of the items have a rating of good or better.

THIS PAGE IS DECLASSIFIED IAW EO 13526

The analysis of the items as to validity coefficients is an important one to make for the instructor as an examiner. However, an equally significant analysis of the items from the point of view of the instructor as a teacher is the one that reveals the specific strengths and weaknesses of the students. The indicated strengths reflect areas where the instructor has been successful in his prime mission; the indicated weaknesses are the points where additional emphasis and instructional time should be focused. The data presented in Table 34 pinpoints the specific items and tells how they were passed or failed by the students on an Air-Force-wide basis. Items which are failed by many students and which in the opinion of the instructors represent fundamental facts or concepts which should be understood by the average student should be taught more effectively next year.

Table 34

Percent of Students Passing Each of the Eighty Items on the Administration and Military Management Examination

100% to 91% Item No.	90% to 81% Item No.	80% to 71% Item No.	70% to 61% Item No.	60% to 51% Item No.	50% to 41% Item No.	40% to 31% Item No.	30% to 21% Item No.	20% to 11% Item No.	10% or less Item No.
11	1	2	3	6	4	12			
14	10	5	9	8	35	23			
17	15	7	13	31	50	63			
19	25	16	24	32	64	72			
26	28	18	27	33	75				
40	29	20	30	42	78				
62	39	21	36	43					
69	41	22	37	53					
	45	34	38	59					
	55	48	44	60					
	57	54	46	79					
	65	67	47						
	66	70	49						
	68	71	51						
	73	76	52						
			56						
			58						
			61						
			74						
			77						
			80						

About forty-five per cent (45) of the test items showed pass-per cents between sixty-one per cent (61%) to eighty per cent (80%). About nineteen per cent (19%) showed pass per cents between eighty-one per cent (81%) to ninety per cent (90%). There was a deficiency of items in the per cent categories of thirty per cent (30%) and below; yet eleven per cent (11%) of the items were in the category ninety-one per cent (91%) to one hundred per cent (100%).

0742

THIS PAGE IS DECLASSIFIED IAW EO 13526

Attention might be drawn to these items were the pass-per cents are fifty per cent (50%) or less. Close scrutiny should be given this group of items as they may reveal student weak spots and indicate to the instructor the curricular sub-topics where instruction is needed or where superior instruction should be offered in subsequent lesson periods.

Aircraft Maintenance Examination

This examination consisted of eighty (80) multiple-choice items designed to measure student understanding of aircraft maintenance engineering principles and procedures. The papers of four hundred (400) students were studied in this analysis.

Test items were analyzed for their discriminating power, that is, their power to differentiate good students from poor students. Good discriminating power is indicated by positive validity coefficients and poor discriminating power is indicated by negative validity coefficients. Validity coefficients may range from -1.00 to 0 to +1.00. A valid test should contain items whose validity coefficients are at least .25 or better. Fifty-six (56) of the items measured up to the standard of .25 or better for a discriminating item. The average validity coefficient for all items was .32, a little higher than the average of .29 on a similar test given last year.

Test items were analyzed for their difficulty (per cent right). The average difficulty was seventy-three per cent (73%). This test was easier than a similar test administered last year, which had an average difficulty of sixty-four per cent (64%). The average difficulty is the average of the pass per cents of the eighty (80) items. The number of items of a specified difficulty is as follows:

	Difficulty (Per cent Right)			
	50% and Below	51% to 90%	91% to 100%	Total Test
Number of Items	8	63	9	80

Test items were analyzed for their discriminating power. Alternative A in Items 2 and 10, Alternative C in Item 25, Alternative B in Item 28, Alternative E in Item 30, and Alternative A in Items 66 and 73 drew no responses at all. These alternatives are evidently not plausible and should be replaced by new alternatives.

The following items had alternatives which misled a disproportionate number of the better students. These alternatives should be reviewed with a view to revision.

Item	Alternative	Item	Alternative
1	E	39	E
4	A	42	B
6	E	45	E
8	C	46	D
12	A	49	B
14	A,B	54	E
17	C	55	E
18	C	62	C
20	E	63	E
25	B	70	A
30	B	75	C
31	A	76	A,C
35	B	79	D
36	B		

In order to obtain a quick overview as to which items were excellent, very good, good, fair and poor, a distribution of the eighty (80) items according to the degree of validity coefficient was made and is presented in Table 35.

0744

THIS PAGE IS DECLASSIFIED IAW EO 13526

Table 35

Validity of Coefficients of the Eighty Items of the Aircraft Maintenance Examination

Coefficients .14 and below (Poor)	Coefficients .15 to .24 (Fair)	Coefficients .25 to .34 (Good)	Coefficients .35 to .44 (Very Good)	Coefficients .45 and above (Excellent)
Item No.	Item No.	Item No.	Item No.	Item No.
12, 17, 20, 22, 26, 30, 31	2, 4, 8, 18, 21, 25, 27, 29, 32, 36, 38, 39, 42, 46, 47, 51, 56	9, 11, 13, 24, 28, 33, 34, 35, 41, 45, 48, 50, 52, 53, 55, 62, 63, 66, 68, 69, 71, 76, 79	1, 3, 6, 7, 10, 14, 16, 19, 37, 40, 43, 49, 54, 57, 61, 64, 67, 74, 75, 77	5, 15, 23, 44, 58, 59, 60, 65, 70, 72, 73, 78, 80

The number and the per cent of the items in each of the five (5) categories is as follows:

Category	Number of Items	Per cent of Total (80)
Excellent	13	16%
Very Good	20	25%
Good	23	29%
Fair	17	21%
Poor	7	9%

About sixteen per cent (16%) of the items are excellent; in all about seventy per cent (70%) of the items have a rating of good or better.

0745

THIS PAGE IS DECLASSIFIED IAW EO 13526

The analysis of the items as to validity coefficient is an important one to make for the instructor as an examiner. However, an equally significant analysis of the items from the point of view of the instructor as a teacher is the one that reveals the specific strengths and weaknesses of the students. The indicated strengths reflect areas where the instructors have been successful in their prime mission; the indicated weaknesses are the points where additional emphasis and instructional time should be focused. The following analysis in Table 36 pinpoints the specific items and tells how they were passed or failed by the students on an Air Force-wide basis. Items which are failed by many students and which in the opinion of the instructors represent fundamental facts or concepts which should be understood by the average student should be taught more effectively next year.

Table 36

Per cent of Students Passing Each of the Eighty Items of the Aircraft Maintenance Examination

100% to 91% Item No.	90% to 81% Item No.		80% to 71% Item No.		70% to 61% Item No.	60% to 51% Item No.	50% to 41% Item No.	40% to 31% Item No.	30% to 21% Item No.	20% to 11% Item No.	10% or Less Item No.
2	12	57	4	56	1	14	13	3	6		
17	18	61	5	64	7	16	37	15			
25	21	66	9	67	8	24	45	70			
26	27	74	19	69	10	55		79			
31	30	75	22	71	11	63					
38	34		23	76	44	65					
48	35		28	77	53	78					
52	36		29		54						
	39		32		58						
	41		33		59						
	42		40		60						
	46		43		62						
	50		47		68						
	51		49		72						
					80						

About forty-four per cent (44%) of the test items showed pass-per cents between sixty-one per cent (61%) and eighty per cent (80%). About twenty-five per cent (25%) showed pass-per cents between eighty-one per cent (81%) and ninety per cent (90%). There was a deficiency of items in the per cent categories of fifty per cent (50% and below; yet eleven per cent (11%) of the items were in the category ninety-one per cent (91%) to one hundred per cent (100%).

Attention might be drawn to those items where the pass-per cents are fifty per cent (50%) or less. Close scrutiny should be given this group of items as they may reveal student weak spots and indicate to the instructor the curricular sub-topics where instruction is needed or where superior instruction should be offered in subsequent lesson periods.

Armament Examination

This examination consisted of eighty (80) multiple-choice items designed to measure student knowledge of technical details and their understanding of principles used in Armament work. For this analysis, 150 student papers were separated into 5 ability groups, using total score as the criterion.

Test items were analyzed for their discriminating power, that is, their power to differentiate good students from poor students. Good discriminating power is indicated by positive validity coefficients and poor discriminating power is indicated by negative validity coefficients. Validity coefficients may range from -1.00 to 0 to +1.00. A valid test should contain items whose validity coefficients are at least .25

or better. Sixty-nine (69) of the 80 items measure up to the standard of .25 or better for a discriminating item. The average validity coefficient for all test items was .45 compared with an index of .22 for a similar test which was administered last year. This represents a considerable improvement in the discriminating power of the test.

Test items were also analyzed for difficulty. The average difficulty of items on this test was 72 per cent correct compared with an average difficulty of 67 per cent correct for items of a similar test administered one year ago. The average per cent difficulty is the average of the pass per cents of the 80 items. The number of items of a specified difficulty is as follows:

	Difficulty (per cent right)			
	50% and Below	51% to 90%	91% to 100%	Total Test
Number of Items	6	62	12	80

Test items were analyzed for their discriminating power. Most of the items were quite effective in discriminating between able and less able students; however, a detailed analysis of test items shows a number of ineffective alternatives which might well be replaced by more plausible distractors. The following alternatives should be replaced, as they were chosen more frequently by good students than by poor ones:

Item	Alternative	Item	Alternative
11	E	40	A, C
30	B	42	D
36	D	56	B
37	E	60	A, C

In order to obtain a quick overview as to which items were excellent, very good, good, fair and poor, a distribution of 80 items according to the degree of validity coefficient was made and is given in Table 37A.

Table 37A

Validity Coefficients of the Eighty Items
of the Armament Examination

Coefficients .14 and below (Poor)	Coefficients .15 to .24 (Fair)	Coefficients .25 to .34 (Good)	Coefficients .35 to .44 (Very Good)	Coefficients .45 and above (Excellent)	
Item No.	Item No.	Item No.	Item No.	Item No.	
19	33	3	4	1	32
24	44	9	11	2	35
41	46	37	13	5	42
	47	38	22	6	51
	48	43	23	7	56
	50	49	26	8	58
	54	52	34	10	59
	57	53	36	12	61
		73	39	14	62
		78	40	15	64
			45	16	68
			55	17	69
			60	18	70
			63	20	71
			65	21	72
			66	25	74
			67	27	75
			80	28	76
				29	77
				30	79
				31	

The number and the per cent of the items in each of the five categories is as follows:

Category	No. of Items	Per cent of Total (80)
Excellent	41	51%
Very Good	18	22%
Good	10	13%
Fair	8	10%
Poor	3	4%

About fifty-one per cent (51%) of the items are excellent; in all about eighty-six per cent (86%) of the items have a rating of good or better.

0748

THIS PAGE IS DECLASSIFIED IAW EO 13526

The analysis of the items as to validity coefficient is an important one to make for the instructor as an examiner. However, an equally significant analysis of the items from the point of view of the instructor as a teacher is the one that reveals the specific strengths and weaknesses of the students. The indicated strengths reflect areas where the instructor has been successful in his prime mission; the indicated weaknesses are the points where additional emphasis and instructional time should be focused. The following analysis in Table 37B pinpoints the specific items and tells how they were passed or failed by the students on an Air-Force-wide basis. Items which are failed by many students and which in the opinion of the instructors represent fundamental facts or concepts which should be understood by the average student, should be taught more effectively next year.

Table 37B

Per cent of Students Passing Each of the 80 Items on the Armament Examination

100% to 91% Item No.	90% to 81% Item No.	80% to 71% Item No.	70% to 61% Item No.		60% to 51% Item No.	50% to 41% Item No.	40% to 31% Item No.	30% to 21% Item No.	20% to 11% Item No.	10% or Less Item No.
5	9	1	2	59	16	21	42	60		
13	12	4	3	61	23	40				
19	15	8	6	68	30	54				
41	17	14	7	74	31	67				
44	24	20	10	80	35					
46	27	26	11		36					
47	34	33	18		56					
48	38	37	22		63					
50	43	51	25		70					
52	45	62	28							
73	49	64	29							
79	55	69	32							
	57	71	39							
	65	72	53							
	66	75	58			77				
	78	76								
		77								

About forty-six per cent (46%) of the test items showed pass-per cents between 61% and 80%. About 20% showed pass-per cents between 81% to 90%.

There was a deficiency of items in the per cent categories of 40% and below; yet 15% of the items were in the category 91% to 100%.

Attention might be drawn to those items where the pass-per cents are 50% or less. Close scrutiny should be given this group of items as they may reveal student weak spots and indicate to the instructor the curricular sub-topics where instruction is needed or where superior instruction should be offered in subsequent lesson periods.

Communications Examination

This examination was made up of eighty (80) multiple-choice items designed to measure student knowledge of technical communications information. The test papers of two hundred and ten (210) students were studied in this analysis.

Test items were analyzed for their discriminating power, that is, their power to differentiate good students from poor students. Good discriminating power is indicated by positive validity coefficients and poor discriminating power is indicated by negative validity coefficients. Validity coefficients may range from -1.00 to 0 to +1.00. A valid test should contain items whose validity coefficients are at least .25 or better. Sixty-one (61) items measured up to the standard of .25 or better for a discriminating item. The average validity coefficient for all test items was .35 compared with an index of .31 on a similar test given last year. This represents a definite improvement in the test.

This year's test was much easier than a similar test administered last year. The difficulty of the test was seventy-one per cent (71%). The average per cent difficulty is the average of the pass-per cents of the eighty (80) items. The number of items of a specified difficulty is as follows:

	Difficulty (Per Cent Right) 50% and below	51% to 90%	91% to 100%	Total Test
Number of Items	12	61	7	80

Test items were analyzed for their discriminating power. Items 2, 3, 40, 45 and 69 were extremely easy and might be replaced by better items. Most of the remaining items had effective alternatives; however, a study of the detailed analysis of test items will reveal other weak alternatives.

The following items had alternatives which were chosen more frequently by good students than by poor ones. These alternatives should be reviewed carefully and revised or replaced:

Item	Alternative	Item	Alternative
1	E	51	C
10	D	56	A
14	B	58	D
17	C	62	D
36	E	65	B
38	C	68	C
39	B	77	B
42	A	78	A
43	C, E	80	C

Items 2, 8, 40, 45 and 69 were extremely easy and might be replaced by better items. Most of the remaining items had effective alternatives.

In order to obtain a quick overview as to which items were excellent, very good, good, fair and poor, a distribution of eighty (80) items according to the degree of validity coefficient was made and given in Table 38.

0752

THIS PAGE IS DECLASSIFIED IAW EO 13526

Table 38

Validity Coefficients of the Eighty Items of the Communications Examination

Coefficients .14 and below (Poor) Item No.	Coefficients .15 to .24 (Fair) Item No.	Coefficients .25 to .34 (Good) Item No.	Coefficients .35 to .44 (Very Good) Item No.		Coefficients .45 and above (Excellent) Item No.
2	3	4	1	31	6
8	20	9	5	35	7

		60	29	79	42
		65	30		46
		73			50
		75			51
		76			53
					55
					57
					59
					77

The number and the per cent of the items in each of the five categories are as follows:

Category	Number of Items	Per Cent of Total (80)
Excellent	20	25%
Very Good	25	31%
Good	16	20%
Fair	11	14%
Poor	8	10%

About twenty-five per cent (25%) of the items are excellent; in all about seventy-six per cent (76%) of the items have a rating of good or better.

The analysis of the items as to validity coefficient is an important one to make for the instructor as an examiner. However, an equally

0753

significant analysis of the items from the point of view of the instructor as a teacher is the one that reveals the specific strengths and weaknesses of the students. The indicated strengths reflect areas where the instructor has been successful in his prime mission; the indicated weaknesses are the points where additional emphasis and instructional time should be focused. The data presented in Table 39 pinpoints the specific items and tells how they were passed or failed by the students on an Air-Force-wide basis. Items which are failed by many students and which in the opinion of the instructors represent fundamental facts or concepts which should be understood by the average student should be taught more effectively next year.

Table 39

Per Cent of Students Passing Each of the Eighty Items of the Communications Examination

100% to 91% Item No.	90% to 81% Item No.	80% to 71% Item No.		70% to 61% Item No.	60% to 51% Item No.	50% to 41% Item No.	40% to 31% Item No.	30% to 21% Item No.	20% to 11% Item No.	10% or less Item No.
2	4	1	46	7	13	6	78	51		
8	16	3	49	10	15	17				
40	23	5	50	11	18	19				
45	24	9	56	21	27	31				
48	35	12	63	22	34	33				
68	41	14	67	25	42	37				
69	52	20	71	29	47	43				
79	54	26	74	44	57	55				
	60	28	75	53		73				
	62	30		58		77				
	65	32		59						
	72	36		61						
	76	38		64						
	80	39		66						
				70						

About forty-eight per cent (48%) of the test items showed pass per cents between sixty-one per cent (61%) and eighty per cent (80%). About nineteen per cent (19%) showed pass-per cents between eighty-one (81%) and ninety per cent (90%). There was a deficiency of items in the per cent categories of forty per cent (40%) and below; yet nine per cent (9%) of the items were in the category ninety-one per cent (91%) to one hundred per cent (100%).

Attention might be drawn to those items where the pass-per cents are fifty per cent (50%) or less. Close scrutiny should be given this group of items as they may reveal student weak spots and indicate to the instructor the curricular sub-topics where instruction is needed or where superior instruction should be offered in subsequent lesson periods.

Introduction to USAF Examination

This examination consisted of eighty multiple-choice items designed to measure student understanding of several topics included in this course. A sample of four hundred (400) student papers were used in the analysis. These papers were separated into five ability groups, using total score as the criterion.

Test items were analyzed for their discriminating power, that is, their power to differentiate good students from poor students. Good discriminating power is indicated by positive validity coefficients and poor discriminating power is indicated by negative validity coefficients. Validity coefficients may range from -1.00 to 0 to +100.

A valid test should contain items whose validity coefficients are at least .25 or better. Seventy-six of the 80 items measured up to the standard of .25 or better for a discriminating item. The average validity coefficient for all test items was .45, an extremely high figure and was slightly higher than the figure reported for a similar test last year.

This year's test items had an average difficulty of 67 per cent correct compared with an average difficulty of 53 per cent correct for a similar test which was administered last year. This probably indicates that the test this year was slightly easier than last year's. The number of items of a specified difficulty is as follows:

	Difficulty (Per cent right)			
	50% and below	51% to 90%	91% to 100%	Total Test
Number of Items	13	61	6	80

Of the 80 items, there were only 7 items which were passed by 90 to 100 per cent of the students.

The following items had alternatives which were chosen more frequently by good students than by poor ones. These alternatives should be reviewed carefully and possibly revised.

Item	Alternative	Item	Alternative
3	B	52	E
10	D	64	C
23	D	65	D
24	[illegible]	66	E
25	D	68	A
46	C, D	73	A
47	D	75	E

An effort should be made to secure alternatives for each item which serve as effective distractors. Most of the items have effective alternatives.

0756

THIS PAGE IS DECLASSIFIED IAW EO 13526

In order to obtain a quick overview as to which items were excellent, very good, good, fair and poor, a distribution of eighty items according to the degree of validity coefficient was made and is given in Table 40.

Table 40

Validity Coefficients of the Eighty Items on the Introduction to USAF Examination

Coefficients .14 and below (Poor) Item No.	Coefficients .15 to .24 (Fair) Item No.	Coefficients .25 to .34 (Good) Item No.	Coefficients .35 to .44 (Very Good) Item No.	Coefficients .45 and above (Excellent) Item No.	
36	1	3	9	2	51
	12	4	14	5	52
	30	17	16	6	53
		19	18	7	54
		25	21	8	56
		31	22	10	57
		38	24	11	60
		46	29	13	62
		47	34	15	63
		66	35	20	64
			37	23	65
			39	26	68
			45	27	69
			55	28	70
			58	32	71
			59	33	72
			61	40	73
			67	41	74
				42	75
				43	76
				44	77
				48	78
				49	79
				50	80

The number and per cent of items in each category is as follows:

Category	No. of Items	Per Cent of Total (80)
Excellent	48	60%
Very Good	18	23%
Good	10	12%
Fair	3	4%
Poor	1	1%

THIS PAGE IS DECLASSIFIED IAW EO 13526

About sixty per cent of the items are excellent; in all about 95 per cent of the items have a rating of good or better.

The analysis of the items as to validity coefficients is an important one to make for the instructor as an examiner. However, an equally significant analysis of the items from the point of view of the instructor as a teacher is one that reveals the specific strengths and weaknesses of the students. The indicated strengths reflect the areas where the instructor has been successful in his prime mission; the indicated weaknesses are the points where additional emphasis and instructional time should be focused. The following tabular analysis pinpoints the specific items and tells how they were passed or failed by the students on an Air-Force-wide basis. Items which are failed by many students and which in the opinion of the instructors represent fundamental facts or concepts which should be understood by the average student should be taught more effectively next year. See Table 41.

Table 41

Per Cent of Students Passing Each of the Eighty Items on the Introduction to USAF Examination

100% to 91% Item No.	90% to 81% Item No.	80% to 71% Item No.		70% to 61% Item No.		60% to 51% Item No.	50% to 41% Item No.	40% to 31% Item No.	30% to 21% Item No.	20% to 11% Item No.	10% or Less Item No.
1	3	8	44	2	60	11	5	53	10	45	
4	14	9	52	7	61	27	6		23		
12	17	15	55	21	62	32	13		37		
30	18	19	65	24	63	48	16		46		
36	22	20	66	33	69	57	50		64		
59	25	26	68	34	70	67	51				
	31	28	73	35	77	72	53				
	38	29	74	39	79	76					
	47	41	75	40	80						
	56	42	78	49							
	71	43		54							

THIS PAGE IS DECLASSIFIED IAW EO 13526

About 51 per cent of the items showed pass per cents of between 61% to 80%. One item had a pass-per cent between 31% to 40% and one item had a pass per cent of between 11% to 20%. No items received pass-per cents of 10% or less; however, there were six items that had pass-per cents of 19% to 100%.

Attention should be drawn to those items where the pass per cents is 50% or less. Close scrutiny should be given to this group of items as they may reveal students weak spots and indicate to the instructor the curricular sub-areas where instruction is needed or where superior instruction should be offered in subsequent lesson periods.

Statistical Control Examination

This examination was made up of eighty (80) multiple-choice items designed to measure student understanding of the principles and procedures of Statistical Control. The papers of two hundred thirty-five (235) students were used for this analysis.

Test items were analyzed for their discriminating power, that is, their power to differentiate good students from poor students. Good discriminating power is indicated by positive validity coefficients and poor discriminating power is indicated by negative validity coefficients. Validity coefficients may range from -1.00 to 0 to /1.00. A valid test should contain items whose validity coefficients are at least .25 or better. The average validity coefficient for all items was .23, a lower figure than the average of .26 for a similar test given last year. There were thirty-six (36) items which met the standard of .25 or better for a discriminating item.

0759

THIS PAGE IS DECLASSIFIED IAW EO 13526

The test items were analyzed for their difficulty, that is, their per cent right. The average difficulty was seventy per cent (70%). This test was of approximately the same difficulty as a test on the same subject administered last year, which had an average difficulty of sixty-eight per cent (68%). The average per cent difficulty is the average of the pass-per cents of the eighty (80) items. The number of items of a specified difficulty is as follows:

	Difficulty (Per cent Right)			
	50% and Below	51% to 90%	91% to 100%	Total Test
Number of Items	10	60	10	80

Test items were analyzed for their discriminating power. There were several items (with validity coefficients less than .25) in which incorrect alternatives drew no student responses. These alternatives, which are listed below, are evidently not plausible and should be replaced with new alternatives.

Item	Alternative	Item	Alternative
9	D	39	D
19	C, E	40	C, E
22	C	46	A, B
28	E	47	E
35	D, E	51	C
37	D	68	D
38	C, D		

Several items such as , 22, 23, 25, 26, 34, 37, 38, 40, 42 and 52 might well be replaced by better items. In the case of the following items, the incorrect alternatives indicated misled a disproportionate number of the better students. These alternatives should be reviewed for revision or replacement.

0760

Item	Alternative	Item	Alternative
1	C, D	39	C
4	E	41	A
5	D	42	A, D
7	B	43	B
8	A, E	45	B, D
9	A	49	E
11	C	51	A, B
12	C, D	52	D
13	B	56	A
15	A	66	C
16	E	68	B
17	D	70	D
18	D	71	A, E
21	B	72	C, D
25	D, E	73	E
26	D, E	74	A, B
29	E	75	E
33	B, C	76	E
34	B	77	D
35	C	80	D
37	E		

It is felt that this examination was of appropriate difficulty but its discriminating power was low. The other seven (7) examinations had high discriminating power and were of approrpiate difficulty.

In order to obtain a quick overview as to which items were excellent, very good, good, fair and poor, a distribution of the eighty (80) items according to the degree of validity coefficient was made and given in Table 42.

Table 42

Validity Coefficients of the Eighty Items
of the Statistical Control Examination

Coefficients .14 and below (Poor) Item No.	Coefficients .15 to .24 (Fair) Item No.		Coefficients .25 to .34 (Good) Item No.		Coefficients .35 to .44 (Very Good) Item No.	Coefficients .45 and above (Excellent) Item No.
7	1	51	5	66	3	57
8 (-.07)	2	54	6	67	4	65
16	9	56	12	69	17	
22	10	73	13	71	20	
23	11	74	14	72	41	
24	15	75	18	80	55	
25	19	76	21		59	
26	27	77	29		62	
31	28		30		64	
34	32		36		78	
37	33		44		79	
38	35		49			
40	39		53			
42	45		58			
43	46		60			
48	47		61			
52	50		63			

The number and the per cent of the items in each of the five (5) categories is as follows:

Category	Number of Items	Per cent of Total (80)
Excellent	2	2%
Very Good	11	14%
Good	23	29%
Fair	27	34%
Poor	17	21%

About two per cent (2%) of the items are excellent; in all about forty-five per cent (45) have a rating of good or better.

The analysis of the items as to validity coefficient is an important one to make for the instructor as an examiner. However, an equally significant analysis of the items from the point of view of the instructor as a teacher is the one that reveals the specific strengths and weaknesses of the students. The indicated strengths reflect areas where the instructor has been successful in his prime mission; the indicated weaknesses are the points where additional emphasis and instructional time should be focused. The data of Table 43 pinpoints the specific items and tells how they were passed or failed by the students on an Air-Force-wide basis.

		31	74						
		33	78						
		34							
		35							
		36							
		53							
		71							

Items which are failed by many students and which in the opinion of the instructors represent fundamental facts or concepts which should be understood by the average student should be taught more effectively next year.

About forty-four per cent (44%) of the test items showed pass-per cents between sixty-one per cent (61%) and eighty per cent (80%). About eighteen per cent (18%) showed per cents between eighty-one per cent (81%) and ninety per cent (90%).

There was a deficiency of items in the per cent categories of fifty per cent (50%) and below; yet twelve (12%) of the items were in the category ninety-one per cent (91%) to one hundred per cent (100%).

Attention might be drawn to those items where the pass per cents are fifty per cent (50%) or less. Close scrutiny should be given this group of items as they may reveal student weak spots and indicate to the instructor the curricular sub-topics where instruction is needed or where superior instruction should be offered in subsequent lesson periods.

Supply Examination

This examination consisted of eighty (80) multiple-choice items designed to measure student understanding of supply procodures. The test papers of two hundred and sixty (260) students were studied in this analysis.

Test items were analyzed for their discriminating power, that is, their power to differentiate good students from poor students. Good discriminating power is indicated by positive validity coefficients and poor discriminating power is indicated by negative validity coefficients. Validity coefficients may range from -1.00 to 0 to +1.00. A valid test should contain items whose validity coefficients are at least .25 or better. Forty-eight (48) of the eighty (80) items measured up to the standard of .25 or better for a discriminating item. The average validity coefficient for all test items was .31, slightly higher than the average of .29 on a similar test administered last year.

This year's test was much easier than a similar test administered last year. The difficulty of the test was seventy-one per cent (71%) correct compared with a difficulty of fifty-seven per cent (57%) correct for last year's test. The average per cent difficulty is the average of the pass-per cents of the eighty (80) items. The number of items of a specified difficulty is as follows:

	Difficulty (Per cent Right)			
	50% and Below	51% to 90%	91% to 100%	Total Test
Number of Items	15	57	8	80

Test items were analyzed for their discriminating power. There were two items, 2 and 62, which were missed more frequently by good students than by poor ones, hence they had negative validity coefficients. These items should be reviewed and revised.

The following alternatives found in items with low discriminating power drew no response and are recommended for replacement:

Item	Alternative	Item	Alternative
1	D	35	D
11	A	55	A
12	E	58	E
32	C, E	75	D, E

The following items had alternatives which were chosen more frequently by good students than by poor ones. These alternatives which were chosen more frequently by good students than by poor ones should be reviewed and revised or replaced.

0765

					76	77
						80

The number and the per cent of the items in each of the five (5) categories is as follows:

Category	Number of Items	Per cent of Total (80)
Excellent	15	19%
Very Good	14	17%
Good	19	24%
Fair	22	28%
Poor	10	12%

About nineteen per cent (19%) of the items are excellent; in all about sixty per cent (60%) of the items have a rating of good or better.

The analysis of the items as to validity coefficient is an important one to make for the instructor as an examiner. However, an equally significant analysis of the items from the point of view of the instructor as a teacher is the one that reveals the specific strengths and weaknesses of the students. The indicated strengths reflect areas where the instructor has been successful in his prime mission; the indicated weaknesses are the points where additional emphasis and instructional time should be focused. The date in Table 45 pinpoints the specific items and tells how they were passed or failed by the students on an Air-Force-wide basis. Items which are failed by many students and which in the opinion of the instructors represent fundamental facts or concepts which should be understood by the average student should be taught more effectively next year.

Table 45

Per Cent of Students Passing Each of the Eighty Items of the Supply Examination

	55								
	57								
	65								
	70								
	72								
	74								
	75								
	76								
	77								

About twenty-eight per cent (28%) of the test items showed pass-per cents between sixty-one per cent (61%) and eighty per cent (80%). About thirty-one per cent (31%) showed pass-per cents between eighty-one per cent (81%) to ninety per cent (90%). There was a deficiency of items in the per cent categories of forty per cent (40%) and below; yet ten per cent (10%) of the items were in the category ninety-one per cent (91%) to one hundred per cent (100%).

0768

THIS PAGE IS DECLASSIFIED IAW EO 13526

Attention might be drawn to those items where the pass-per cents are fifty per cent (50%) or less. Close scrutiny should be given this group of items as they may reveal student weak spots and indicate to the instructor the curricular sub-topics where instruction is needed or where superior instruction should be offered in subsequent lesson periods.

Transportation Examination

This examination consisted of eighty (80) multiple-choice items designed to measure student knowledge of Transportation procedures. A sample of 190 student papers were used in this analysis. These papers were separated into five (5) ability groups, using total score as the criterion. Tests items were analyzed for their discriminating power, that is, their power to differentiate good students from poor students. Good discriminating power is indicated by positive validity coefficients and poor discriminating power is indicated by negative validity coefficients. Validity coefficients may range from -1.00 to 0 to ≠1.00. A valid test should contain items whose validity coefficients are at least .25 or better. Sixty-three (63) items had a validity coefficient of .25 (standard) or better. The average validity coefficient was .40, as compared to an average of .25 for last year. Three items (27, 31 and 37) had negative validity coefficients, that is, they were answered correctly by a greater number of poor students than good students.

This year's test items had an average difficulty of sixty-eight per cent (68%), the same as for a similar test administered last year. The average per cent difficulty is the average of the pass-per cents of the eighty (80) items. The number of items of a specified difficulty

THIS PAGE IS DECLASSIFIED IAW EO 13526

is as follows:

	Difficulty (Per cent right)			
	50% and below	51% to 90%	91% to 100%	Total Test
Number of Items	11	66	3	80

Of the eighty (80) items there were only four (4) items which were passed by ninety to one hundred per cent (90-100%) of the students.

The alternatives listed below misled a disproportionate number of the better students. These alternatives should be studied for revision before the next administration of this examination.

Item	Alternative	Item	Alternative
2	C	44	E
5	C	45	D
10	B	48	A, E
15	B	49	A
21	A	51	E
25	B, E	52	C, D
27	C	54	D
30	E	65	C
31	B	67	A
35	E	68	A
37	B, E	69	E
39	E	72	D
41	A	73	A
42	D	78	A, C

In order to obtain a quick overview as to which items were excellent, very good, good, fair, and poor, a distribution of eighty (80) items according to the degree of validity coefficient was made and is given in Table 46.

Table 46

Validity Coefficients of the Eighty Items on the Transportation Examination

Coefficients .14 and below (Poor) Item No.	Coefficients .15 to .24 (Fair) Item No.	Coefficients .25 to .34 (Good) Item No.	Coefficients .35 to .44 (Very Good) Item No.	Coefficients .45 and above (Excellent) Item No.	
21	10	17	1	2	51
27 (-.01)	15	19	8	3	54
31 (-.01)	25	22	11	4	55
37 (-.03)	41	24	14	5	59

About fifty-six per cent (56%) of the items showed pass per cents between sixty-one per cent (61%) to eighty per cent (80%). About twenty-six per cent (26%) showed pass per cents between eighty-one per cent (81%) and ninety per cent (90%). There was a deficiency of items from thirty per cent (30%) and below.

Attention might be drawn to those items where the pass per cents are fifty per cent (50%) or less. Close scrutiny should be given this group of items as they may reveal student weak spots and indicate to the instructor the curricular sub-topics where instruction is needed or where superior instruction should be offered in subsequent lesson periods.

CHAPTER V

RESULTS OF THE AIR ROTC QUALIFYING EXAMINATION RQ-3-1949

Nature and Uses of the ROTC RQ-3 Test

The ROTC RQ-3 examination is one of the common verbal type tests for the measurement of general learning ability or of scholastic aptitude. This examination is divided into two parts, Part I, Language and Part II, Mathematics.

The RQ-3 examination was administered to each First Year Basic AF ROTC student during the academic year 1948-49. The test results afford an overall estimate of the general level of the learning caliber of the student at the various AF ROTC schools. There are several benefits that accrue as a result of the administration of RQ-3 test:

1. In a general way it affords an objective and scientific means of making a check inventory of a critical requirement of all potential officers--superior mental ability.
2. The test may be utilized as one method of measuring the extent to which students are attaining achievement on course examinations approximately commensurate with their mental alertness.
3. In the event the RQ-3 or an equivalent form of this test is given annually essential and necessary comparisons can be made over the years as to the quality of students entering and remaining in the Air ROTC program. It will help to answer the question as to the caliber of students that are electing to take the Air ROTC courses. The results

0774

THIS PAGE IS DECLASSIFIED IAW EO 13526

of this test can be used to answer the question as to whether better, equally capable or poorer students stay with the ROTC program and take the advanced courses of instruction when compared with the freshmen group of students.

4. The results of the RQ-3 test gives the instructor a rough estimate of the range, and level of learning ability of his students and therefore, where necessary he should reflect these facts by appropriate modifications in reference materials, visual aids, motivation, teaching methods and standards of expected achievement.

5. In the event that a similar type of scholastic learning ability test is administered at the first advanced course year, an adequate picture of the mental caliber of potential officer personnel can be obtained.

6. The test results of the RQ-3 examination can be utilized in certain special circumstances, for example, in the event of a sudden curtailment in funds when the number of students must be reduced, the better qualified students could be selected for training.

7. It is conceivable that the results of a mental ability test can be utilized as one measure, in conjunction with others, which may be used appropriately in selecting the type of initial assignment given the graduated student officer or for selection of officer graduates for special advanced training.

8. The results of the RQ-3 can be utilized in setting up acceptable standards of student attainment on each of the course examinations.

In summary, while the results of the ROTC RQ-3 examination may be utilized in valuable ways, several qualifying statements need to be posited:

a. The results for groups such as mean standard scores for each school are more reliable than the scores for individual students.

b. Because of the very nature of a short group test of the RQ-3 type, the score of an individual student will be only a rough estimate of his general learning ability.

c. Other appraisals, ratings, and measures need to be employed in conjunction with mental test results in the overall evaluation of each individual student.

School Results on the RQ-3 Test

In order to obtain an indication of the mental caliber or scholastic aptitude of incoming ROTC students, a survey type test of intelligence, the ROTC RQ-3, was administered to 19,660 students in 112 schools throughout the United States. The results by air force and for all air forces combined are given in Table 48.

Table 48

Results of the ROTC Qualifying Examination for 112 AFROTC Schools 1948-49

Air Force	No. of Students	Mean Standard Measures	Relative Rank of Air Force
First Air Force	2218	135	1.0
Fourth Air Force	2865	125	4.0
Ninth Air Force	4940	127	2.5
Tenth Air Force	5420	127	2.5
Twelfth Air Force	2269	123	5.5
Fourteenth Air Force	1948	123	5.5
Total	19,660	127	

0776

The First Air Force with an average score of 135 achieved top rank.

A distribution of the mean standard scores of all participating Air ROTC schools was made. In addition, percentile rank equivalents of the mean standard scores were calculated. Percentile ranks are points in a series of scores below which lie a given percentage of the total number of schools. A percentile of fifty (50) means that the school attained a score below which approximately 50% of the school mean scores lie and above which the other 50% lie. A percentile of 99 is the highest or best percentile ranking and the first (1) percentile is the lowest or the poorest percentile ranking. The distribution of mean standard scores and percentile rankings for the 112 schools are given in Table 49. The left half part of Table 49 shows that the school averages on the RQ-3 test range from 107 to 145. Of the 112 schools, 97 of them or 87% attain mean scores between 119 and 133. With such wide variation in student scholastic aptitude one can reasonably expect wide range in achievement; and that in evaluating student course achievement at the various schools, one must seriously consider this differential in learning ability.

Table 49
Distribution of School Average Standard Scores and Selected Percentiles on the ROTC RQ-3 Examination

Distribution of Averages		Score Value of Percentiles	
School Average Scores	No.	Average Score	Percentile
143-145	1	144	99%
140-142	3		
137-139	4		
134-136	7	135	90%
131-133	10	131	80%
128-130	17	128	70%

Distribution of Averages		Score Value of Percentiles	
School Average Scores	No.	Average Score	Percentile
125-127	23	127	60%
		126	50%
		124	40%
122-124	28	123	30%
		122	20%
119-121	19	120	10%
116-118	5		
113-115	2		
110-112	0		
107-109	1	107	1%
Total	112		

Table 50 lists the RQ-3 mean standard scores of each of the schools participating in this testing survey. No norms or national standards for the RQ-3 test are currently available and at present the Air Force-wide medium of 126 (P_{50}) may be taken to represent the national norm. The RQ-3 tests results as shown in Table 50 will serve mainly to give a good description of the nature of the Air ROTC freshman student personnel. Subsequent systematized annual testings will afford data which can be organized and treated for optimum benefits to the Air ROTC programs as outlined in the opening paragraphs of this Chapter.

CHAPTER VI

APPROACHES TO THE EVALUATION OF THE EFFECTIVENESS OF INSTRUCTION

Purpose

An important question that may be raised is: Do the Air ROTC schools achieve rankings on the course examination commensurate with their relative ranks as achieved on the RQ-3 test? A comparison of the relative rankings among the air forces on the RQ-3 test, the Introduction to USAF and the Administration and Military Management Examinations is presented in Table 51.

TABLE 51

Relative Rankings Among the Six Air Forces on the ROTC RQ-3 Test, the Introduction to USAF and Administration and Military Management Examinations

Air Force	ROTC RQ-3 Test Relative Rank Among Air Forces	Introduction to USAF Examination Relative Rank Among Air Forces	Administration & Mil Management Relative Rank Among Air Forces
First Air Force	1	1	1
Fourth Air Force	4	3	2
Ninth Air Force	2.5	2	4
Tenth Air Force	2.5	4.5	3
Twelfth Air Force	5.5	6	6
Fourteenth Air Force	5.5	4.5	5

In general, there seems to be some relationship between the three sets of rankings. The First Air Force has a ranking of 1 on all three tests; the Twelfth and Fourteenth Air Forces are low or lowest on all three tests. In other words, groups of students with greater mental ability also tend to achieve, other things being equal, superior results on the course examinations, Introduction to USAF and Administration and Military Management.

THIS PAGE IS DECLASSIFIED IAW EO 13526

In a previous section of this report a brief survey of the school average scores showed a wide variation in test performance. Various factors affect student performance on examinations. One of the most critical of these factors is the mental caliber of the students concerned. Since mental ability positively affects student accomplishment this factor should be considered in any testing program where one of the purposes for which an examination is utilized is the evaluation of the effectiveness of instruction. It is manifestly unfair to draw conclusions concerning the effectiveness of two instructors on the basis of their student performance on an achievement test if the class of one instructor is brighter mentally than the class of the other instructor. Therefore, some method must be utilized whereby due allowance is made for the mental ability differential existing between the two classes which are to be compared. The method employed here while admittedly not too refined will provide approximate estimates of inter-school accomplishments. At any rate, it is a forward step in the direction of fairer inter-school comparison in that account is taken of the facts of mental ability or scholastic aptitude differences that are known to exist from school to school.

Moreover, it should be clearly understood that achievement examinations should never be employed as the sole instrument to evaluate the instructor's teaching effectiveness. Other supplementary and corroborative evidence must be utilized.

The ROTC RQ-3 examination was used to measure mental ability or scholastic aptitude. This test was administered to the students during their freshmen year. While it would have been better to have used RQ-3 test ratings of the students who remained and took the advanced courses, this could not be done because mental test ratings of the advanced students were not available. Moreover, since we are not dealing with a comparison of one student with another student but between groups of students that is, schools, the relative standings of the various schools in mental ability will probably not change much from the first to the second years. A further assumption needs to be made, however, and that is that the attrition rates are not affected too seriously by the withdrawal of disproportionate numbers of above, average, or below average students when the decision to continue with the advanced courses is made. It is expected that in future reports of this nature mental ratings of students who are taking the advanced courses will be available for use.

Method

Essentially the method that will be employed to evaluate instruction will be the comparison of the two percentile positions achieved by a school, namely, the percentile achieved by the school on the achievement examination will be compared by the percentile attained by the same school on the ROTC RQ-3 test. Percentiles indicate relative positions among a group of schools. Schools should approximately achieve to a degree that is commensurate with the mental caliber of its students. If the mental caliber of students of a school is about average then, other things being equal, they should as a group attain an average mark on the achievement or course examination. Again, if a school places near the top of the group of school, for example, at P90 or the ninetieth percentile on the mental test, then one might expect that school to achieve somewhere near the ninetieth percentile. In other words, the percentile ranking of the school on the RQ-3 test may furnish an approximate indication of expected relative position on an examination given to schools whose students took the same advanced course.

THIS PAGE IS DECLASSIFIED IAW EO 13526

Evaluating Instructions in Introduction to USAF

Table 52 gives the percentile rankings of the schools on the basis of the RQ-3 test results. A distribution of the school average scores on the mental test was made and eleven percentiles P97, P90, P80, P70, P60, P50, P40, P30, P20, P10, and P1 were calculated. These percentiles for the RQ-3 test serve as expectancy indices, that is, furnish an indication of estimated relative position on course examination.

TABLE 52

Distribution of School Averages and Selected Percentiles on the ROTC RQ-3 Examination

Distribution of Averages		Score Value of Percentiles	
School Average Scores	No.	Average Score	Percentile
143-145	1	144	99%
140-142	3		
137-139	4		
134-136	7	135	90%
131-133	10	131	80%
128-130	17	128	70%
125-127	23	127	60%
		126	50%
		124	40%
122-124	28	123	30%
		122	20%
119-121	19	120	10%
116-118	5		
113-115	2		
110-112	0		
107-109	1	107	1%
Total	112		

The ROTC RQ-3 test was given to 19,660 students in 112 different schools. The left half part of Table 52 shows that the school averages on the RQ-3 test range from 107 to 145. Of the 112 participating schools, 97 of them or 87% attain mean scores between 119 and 133. With such wide variation in student scholastic aptitude one can reasonably expect differential achievement. Moreover, evidence of effective utilization

0785

THIS PAGE IS DECLASSIFIED IAW EO 13526

of student personnel would be reflected in student achievement that conforms approximately to the mental ability differences among the schools.

Table 53 shows the percentile positions for each school on both the ROTC RQ-3 and Introduction to USAF examination.

TABLE 53

Actual Achievement School Percentile Ratings,
Placement of 112 Schools on the Introduction to USAF Examination

(Left side of table, printed sideways: Achievement Expectancy Placement School Percentile Ratings of 112 Schools on the RQ-3 Test.)

	No. of Schools	Group VC 0% to 20%	Group IVC 21% to 40%	Group IIIC 41% to 60%	Group IIC 61% to 80%	Group IC 81% to 100%
Group IR	22	3	2	6	4	7
81% to 100%		14%	9%	27%	18%	32%
Group IIR	21	4	4	1	4	8
61% to 80%		19%	19%	5%	19%	38%
Group IIIR	22	5	5	5	6	1
41% to 60%		23%	23%	23%	27%	4%
Group IVR	19	3	6	2	1	7
21% to 40%		16%	32%	10%	5%	37%
Group VR	28	8	8	7	4	1
0% to 20%		29%	29%	25%	14%	3%
TOTAL	112	23	25	21	19	24

Along the top of the table are percentile intervals for the course examination and along the left hand side of the table are the percentile intervals for the RQ-3 test. The percentiles have been grouped into fifths so that Group I represents the top fifth, that is, percentiles 81 to 100 and Group V represents the bottom fifth, that is, percentiles 20 and below.

0786

THIS PAGE IS DECLASSIFIED IAW EO 13526

Groups II, III and IV represent corresponding intermediary fifths. For easy reference and increased clarity successive fifths on the RQ-3 test are labeled Group IR, Group IIR, Group III R, Group IVR and Group VR; the successive fifths on the course examination are labeled Group IC, Group IIC, Group IIIC, Group IVC and Group VC.

Of the 112 schools 22 of them placed in Group IR on the RQ-3 test, 21 placed in Group IIR, 22 in Group IIIR, 19 in Group IVR and 28 in Group VR.

Of the 22 schools whose RQ-3 average score placed them in Group IR, 3 placed in the bottom fifth (Group VC) on the course examination, 2 in Group IVC, 6 in Group IIIC, 4 in Group IIC, and 7 in Group IC. Therefore, of the 22 Group IR schools which may be expected to achieve in Group IC on the course examination only 7 or 32% actually achieved that standing, 4 or 18% actually achieved a Group IIC rating, 6 or 27% actually achieved a Group IIIC rating, 2 or 9% actually achieved a Group IVC rating and 3 or 14% achieved a Group VC rating. One may reasonably conclude that schools whose RQ-3 grouping was IR but who actually achieved in Groups IIIC, IVC and VC should strive for better results next year. Assuming of course that the present utilization of RQ-3 results is a valid one. If we combine the percents for Groups IC and IIC we may say that about 50% of Groups IR approximately achieved expected achievement.

Of the 21 schools whose RQ-3 average score placed them in Group IIR, 38% placed in Group IC, 19% in Group IIC, 5% in Group IIIC, 19% in Group IV C and 19% in Group VC. It may be concluded that schools whose RQ-3 grouping was IIR but who actually achieved in Groups IVC and VC should strive to improve their ranking next year. If we combine the percents for Groups IIIC, IIC and IC we may say that about 62% of Group IIR achieved or surpassed expected achievement. It should be noted that of the Group

THIS PAGE IS DECLASSIFIED IAW EO 13526

IIR while 19% actually achieved a Group IIC rating, 19% of them also achieved a Group VC rating, that is, the lowest rating.

Of the 22 schools whose RQ-3 average score placed them in Group IIIR 4% placed in Group IC, 27% in Group IIC, 23% in Group IIIC, and 23% in Group VC. It may be concluded that schools whose RQ-3 grouping was III (Group IIIR) but who actually achieved in Group VC should strive to improve their ranking next year. If we combine the percents for Groups IC to IIIC we may say that about &&% of Group IIIR achieved or surpassed expected achievement.

Of the 19 schools whose RQ-3 average score placed them in Group IVR, 37% placed in Group IC, 5% in Group IIC, 10% in Group IIIC, 32% in Group IVC and 16% in Group VC. It may be concluded that schools whose RQ-3 grouping was IVR but who actually achieved in Group VC should strive to improve their ranking. One should make note of the fact that 37% of the Group IVR achieved in Group IC. In other words, the performance of some of these schools in Group IVR is as good or better than that for some of the schools in Group IR and Group IIR. If we combine the percents for Group IC to IVC, we may say that about 84% of Group IVR achieve or surpass expected achievement.

Of the 28 schools whose RQ-3 average score placed them in Group VR, 3% placed in Group IC, 14% in Group IIC, 25% in Group IIIC, 29% in Group IV and 29% in Group V. As a group, Group VR is achieving as good as one can expect from students of lower mental caliber.

<u>Summary of Findings</u>

The findings may be listed as follows:

1. The differential between course achievement and expected achievement is greatest among the top caliber schools. Every effort

should be made to utilize student time to produce superior performance commensurate with their superior talents.

2. About 50% of the schools in the top fifth on the RQ-3 test approximately attained expected achievement.
3. About 62% of the schools in the second top fifth in the RQ-3 test reached or surpassed expected achievement.
4. About 77% of the schools in the third fifth on the basis of the RQ-3 test attained or surpassed expected achievement.
5. About 84% of the schools in the lower fourth fifth on the RQ-3 test achieved or surpassed expected achievement.
6. As a group the lowest group in the RQ-3 test achieved as well as may be expected.

In subsequent surveys where both an achievement test and scholastic aptitude test are to be utilized as part of the program of evaluation of effectiveness of instruction, it is contemplated that another form of the RQ-3 test be administered to advanced students, for these are the students who will eventually graduate as commissioned officers. Mental testing of ROTC junior students would furnish an assessment of the mental caliber of potential officer personnel and will at the same time afford mental ratings the recency of which would make for a more adequate comparison with concurrent achievement examinations.

The analysis of the effectiveness of instruction in Introduction to USAF has served as an example in the evaluation of student achievement. In future course examination surveys when appropriate mental ability tests also will be given to the students, evaluation of achievement in the other courses will be reported in more detail.

THIS PAGE IS DECLASSIFIED IAW EO 13526

COMPARISON OF RESULTS OF AIR ROTC COURSE EXAMINATIONS 1948-1949 and ROTC QUALIFYING EXAMINATION RQ-3-1949

Percentile Ranks of All Air ROTC Schools on Course Examinations and ROTC RQ-3

In order to make adequate comparisons as to the achievement among the schools on different examinations, it is necessary to transmute raw test scores into a common system of grading. A simple method that may be utilized with this group of eight tests and student populations is the percentile ranking procedure. The distribution of the school averages for each examination was divided into percentiles.

Percentile ranks based on less than thirt schools are to be regarded as best estimated values, however, they were calculated in order to present a complete picture of the rankings of all schools on all course examinations.

Table 54 is a summary table; the table presents the percentile ranks on the course examinations and the RQ-3 test for all schools in the program.

0790

Yale University	94	89							92	97

*These RQ-3 percentiles may be compared only with those of Introduction to USAF examination. (See also P. 110).

**It should be noted that the course percentile ranks at schools where two or more courses are taught can be only crudely compared. Percentile ranks for one course are not strictly comparable to the percentile ranks in another course because the set of schools involved in the two courses concerned are rarely if ever identical. The greater the degree of overlapping of schools giving instruction in both courses the more valid will be the inter-course percentile comparisons at any one school. Comparable standard scores will be employed in future reports.

THIS PAGE IS DECLASSIFIED IAW EO 13526

An examination of the course percentile ratings attained at each school gives one type of indication of the level of instruction reached by instructor-personnel at that school. Instructor personnel at all schools should carefully examine these rankings. A common practice, though not too accurate a recommendation, followed by personnel in a supervisory capacity is to assume that schools in the lowest ten, twenty, or thirty per cent of the schools taking an achievement examination are doing very poorly. This may, or may not, be true. If these students from a school in the lowest percentiles are as a group much below average in mental ability, or scholastic aptitude, their poor achievement will probably be low as compared to better able students, but the former students may still be achieving up to their mental input. On the other hand, when a school with very superior students is achieving an average score, these students as a group are not functioning up to their maximum capacity. For the latter group of students, changes in methods of instruction need to be made and more often than not better ways of motivation need to be employed.

THIS PAGE IS DECLASSIFIED IAW EO 13526

In order to more adequately consider achievement in relation to intelligence, Table 54 gives both the percentile ranks on the course examinations and the qualifying examination, ROTC RQ-3. The column headed "Percentile Ranks on Air ROTC RQ-3, 1st Year Basic Students" gives percentile rankings in mental alertness. For each school and on each examination taken at this school, the percentile rankings on the course examinations may be compared. The comparison of the course examination percentiles and the RQ-3 percentiles given in Table 54 can not afford too sound a base upon which to draw definite conclusion because the ROTC RQ-3 test was given to freshmen students, whereas the course examinations were given to junior and senior students. However, hints and clues as to the effectiveness of instruction may be learned from comparisons of course examination percentiles and mental ability percentiles for schools where the discrepancy between these two percentile rankings are greatest. The most adequate comparison between achievement percentiles (course examination) and ability (ROTC RQ-3) percentiles can be for the course examination, Introduction to USAF, because the same set of schools took the latter and the ROTC RQ-3. For similar comparisons between other course examinations results, e.g., Armament and ROTC RQ-3 results, re-ranking on the RQ-3 test results for schools taking the armaments examination must be made. This type of analysis has not been made and, while important, has been deferred to next year's report when more adequate RQ-3 test results will be made available. See Appendix 1 for the evaluation of instruction in the other course examinations.

Of the 112 schools which took the Introduction to USAF, 51 schools received achievement percentiles higher than their mental ability per-

0799

centiles, 9 schools had identical percentile rankings in achievement and mental ability, while 52 schools attained achievement percentiles less than their mental ability percentiles. Of these 52 schools, 17, or about thirty-three per cent of them, had achievement percentiles that were 37 percentile points or more below their ability percentiles. Therefore, the achievement of schools showing achievement percentiles which were 37 or more percentile points less than their ability percentiles may need to be examined more closely, with a view toward possible modifications in the instructional programs.

A distribution of the achievement and ability percentile differences for the 52 schools where the achievement percentiles were less than the ability percentiles is given in Table 55.

TABLE 55
Achievement Deficiencies in Terms of Percentile Points
at 52 Air ROTC Schools

Introduction to USAF Examination

Intervals of Achievement Ability Percentile Differences	No. of Schools
- 73 to -78	1
- 67 to -72	2
- 61 to -66	2
- 55 to -60	1
- 49 to -54	3
- 43 to -48	4
- 37 to -42	4
- 31 to -36	2
- 25 to -30	8
- 19 to -24	5
- 13 to -18	5
- 7 to -12	8
- 1 to - 6	7
Total	52

The median deficiency was about -25 percentile points.

0800

THIS PAGE IS DECLASSIFIED IAW EO 13526

On the other hand, of the 112 schools which took the examination, Introduction to USAF, 51 schools received achievement percentiles higher than their mental ability. A distribution of these achievement and ability percentile differences for the 51 schools where the schools achievement percentiles were greater than the ability percentiles is given in Table 56.

TABLE 56
Achievement Proficiency in Terms of Percentile Points at 51 Air ROTC Schools

Introduction to USAF Examination

Intervals of Achievement Ability Percentile Differences	No. of Schools
+ 67 to + 72	4
+ 61 to + 66	3
55 to + 60	2
+ 49 to + 54	6
+ 43 to + 48	0
+ 37 to + 42	3
+ 31 to + 36	3
+ 25 to + 30	10
+ 19 to + 24	2
+ 13 to + 18	7
+ 7 to + 12	5
+ 1 to + 6	6
Total	51

Of these 51 schools, 17, or about thirty-three per cent of them had percentiles that were about 38 percentile points or more above their ability percentiles. The selection of the top third of the group, while arbitrary, may be considered as a standard of achievement in instructional effectivness, and schools which have attained about 38 percentile points or more above their ability percentile standing are probably achieving at a high level of merit. The median is about + 28 percentile points.

CHAPTER VII

SUMMARY AND CONCLUSION

Role of Air-Force-Wide Examinations

Air-force-wide course examinations may be utilized to answer a prime question, "Are Air Force ROTC schools achieving the objectives that they are supposed to reach?" These examinations can be used to guide and motivate learning, to measure how much, how well, and how rapidly each student has progressed, to serve as a basis for the removal of individual and class difficulties, to help evaluate the achievement of each student in terms of his ability and effort and to give the instructor one reading as to how well his instruction is received by his students. Moreover, when supplemented by other subjective measures, the results of objective course examinations provide a factual basis for recommendations for changes in personnel, procedures, and policies.

Air-force-wide course examinations are deemed necessary and therefore will continue to be administered as part of the instructional and evaluational phases of the educational program. Since many and diverse types of schools are involved in the Air Force ROTC program, a common standard yardstick for the evaluation of instruction is vital for valid appraisal and comparison of schools concerned. Furthermore, cooperation among teachers planning to cover requirements previous to the course examination, the discussion of aims and the basis for selecting material, the acceptance of a distinctive core of minimum essentials for each unit of study, and the equalization of standards among different teachers, are among the definite benefits that may be derived from a good evaluation program. However, if uniform examinations are to be utilized effectively, there must be a realization both by the supervising officer and the instructor that these standard course examinations do. measure at least the minimum essentials

THIS PAGE IS DECLASSIFIED IAW EO 13526

for a course of study, and that an instructor's most valuable service to the program lies in the individual contribution that each instructor gives to his classes in addition to covering the content agreed upon.

In the future, the course examinations will be more systematically constructed with the planned cooperation of the instructors in the field. The examinations will henceforth be constructed so as to be as diagnostic as is feasible. One approach that will be employed to make the course examinations more diagnostic is to group test items in topical sub-groups.

Should course examinations be administered annually, or twice a year? The advantages and disadvantages for course examinations twice a year are still being weighed and no decision has yet been reached.

It is recommended that these examinations be given in lieu of the end-of-term examination, and that the results of this examination contribute to the student's final term grade.

Where schools have not already done so, course examination marks should be entered on each student's record card or file.

Course Achievement of Air Force ROTC Schools

The Air Force ROTC course examinations were administered to 8092 students in 112 colleges and universities throughout the United States. The examinations covered the areas in Administration and Military Management, Aircraft Maintenance Engineering, Armament, Communications, Introduction to USAF, Statistical Control, Supply and Transportation. The latter examinations are achievement tests which cover the important facts, knowledges and understandings in each of the eight Air Force ROTC courses.

The number of schools taking each course examination varied; 112 took the Introduction to USAF examination, while only seven took the Armament examination.

The results of each of the eight examinations reveal a wide range of student achievement.

0803

The mean or average scores of the eight tests ranged from 55 (Aircraft Maintenance) to 48 (Transportation), and therefore may indicate unequal test difficulty. The question of inter-test difficulty can not be answered unless the mean mental abilities of the various examination groups are known.

The variability in the achievement of the various schools in each examination was wide. More often than not, schools with the lowest means achieved roughly on the average only half as much as the schools which returned the highest examination averages. In Armament, the school with the lowest average achieved roughly about forty per cent as much as the schools with the highest averages. In Statistical Control and Supply, schools with the lowest means achieved about 66 per cent as much as the schools with the highest averages. These inter-school accomplishment quotients are crude overall evaluations.

As an aid in interpreting the school test results, the distribution of school average scores for each examination has been divided into percentiles. Percentiles are points in a distribution of schools below which lie a given percentage of the total number of schools. Schools attaining averages in the bottom 30 per cent of the schools taking a particular course examination may find it highly desirable to initiate changes in methods of instruction, to heighten student interest, and to better utilize curricular materials. However, in evaluating the achievement of the latter group of schools, it is necessary to take into consideration the mental ability of the students concerned.

<u>Consistency of Achievement on Course Examinations Among Air Force ROTC Schools</u>

To what degree do Air Force ROTC schools maintain their rank of merit on 1947-1948 and 1948-1949 course examinations? The degree of correspondence or correlation between these two sets of school rankings can be roughly described as high, marked or substantial, low or negligible. The course examinations

0804

where high or substantial positive correlations were found were those for Armament, Introduction to USAF, and Administration and Military Management. The three course examinations where the correspondence between the two annual rankings were lowest were Aircraft Maintenance, Statistical Control, and Transportation. In the latter instances, the changes in status may be due to several factors as changes in instructor personnel, student ability and motivation, course content and the like.

It should be noted that for some examinations, the number of schools was small, and hence the results are merely suggestive. Can the schools be judged by the average scores on course examinations achieved by students? Considered for a series of examinations, there seems to be a level maintained by different schools. When the instructional objectives are the same, and the abilities of the students are approximately the same, this teaching level may be considered indicative of the school.

Item Analysis of Air Force ROTC Course Examinations

Each of the eight course examinations contained eighty items. Each item was analyzed for two important aspects, validity and difficulty. A valid test of the type employed in this annual survey should contain items whose validity coefficients are close to .25 or better. The three course examinations having the highest per cent of items meeting the standard of .25 or better are Introduction to USAF, Armament, and Administration and Military Management. Of the eight examinations, all except that on Statistical Control met acceptable standards from the point of view of item validity. The item validities of the 1948-1949 examinations showed improvement of those for the 1947-1948 course examinations. The examination in Introduction to USAF ranked first in both years. As a group, the 1948-1949 examinations showed a high order of overall item validity.

Each test item was analyzed for its difficulty, that is, the number or per cent of the students who were able to pass the item. All eight examinations showed a deficiency of item-difficulty per cents in the intervals from 30 per cent and below. The bulk of the item-difficulty per cents were in the interval 61% to 90%. There were too many easy items (100% to 90% difficulty) on all examinations except, perhaps, that in Transportation. In all eight examinations the average per cent difficulty for 1948-1949 was equal or higher than those for 1947-1948. The average of the eight average per cent item-difficulties for 1947-1948 was 63.6%, while the average of the eight average per cent item-difficulties for 1948-1949 was 70.2%. It is felt that for this type of annual examination, and in view of the purposes to which it is anticipated that it will be put, the average difficulty of a course examination should not go beyond 65 to 70 per cent.

The analysis of items as to validity coefficients is an important one to make for the instructor as an examiner. However, an equally significant analysis of the items from the point of view of the instructor as a teacher is the one that reveals the specific items which were passed or failed by the students. Attention might be drawn to those items where the pass-per cents are 50% or less. Close scrutiny should be given this group of items as they may reveal student weak spots and indicate to the instructor the curricular sub-topics where instruction is needed or where superior instruction should be offered in subsequent lesson periods. Moreover, items which were failed by many students and which, in the opinion of the instructors, represent fundamental facts or concepts which should be understood by the average student should be taught more effectively next year.

Results of the ROTC Qualifying Examination RQ-3 -- 1949

The RQ-3 examination, a survey type test of learning ability, was administered to all 19,660 First Year Basic AF ROTC students in 112 schools during the academic year 1948-1949. There are several benefits that accrue as a result of the administration of the RQ-3:

THIS PAGE IS DECLASSIFIED IAW EO 13526

1. It affords a scientific means of checking on the mental ability level of potential commissioned officers who select, drop out, or advance through the Air Force ROTC program. A check inventory of this type is basic to a properly administered personnel selection, classification, and utilization program.
2. The RQ-3 test can be utilized to evaluate student accomplishment in relation to their mental ability.
3. The test supplies objective psychological data which the instructor should reflect by appropriate modifications in teaching techniques, motivation and curricular materials.
4. The test results can be used to help set up equitable standards of achievement for large groups of schools with wide variations in learning ability.
5. The test results will supply essential data for future survey, research, and evaluation projects.

Because of the above advantages, mental ability testing programs should be continued and amplified consistent with practicality and the needs of the service. However, because of the very nature of a short group test of the RQ-3 type, the reliability of an individual score will not be as reliable as the mean standard scores of a school. In view of this fact, it may be justified if a longer and more reliable test be substituted. Because of certain difficulties attendant upon the administration of a longer mental ability test, it might be desirable to use an equivalent RQ-3 test at the freshman year and the longer and more reliable test in the advanced years.

The results on the RQ-3 test showed wide variations among the 112 schools. The mean standard school scores ranged from 107 to 145. With such wide variation in learning ability we can reasonably expect a wide range in achievement; and that in evaluating student course achievement one must seriously consider this differential in learning ability. No forms for the ROTC RQ-3 test are currently available and for the present the Air Force-wide median of 126 may be taken to represent the national standard. Of the six Air Forces, the First Air Force, with an average score of 135, achieved top rank.

Evaluation of the Effectiveness of Instruction

A brief survey of the school average course scores showed a wide variation in test performance. Since mental ability of the students concerned positively affects student accomplishment, this factor should be considered in any appraisal of instruction. A method which combined the results on the ROTC RQ-3 test and the course examination was utilized whereby due allowance was made for mental ability differential existing between schools. The method employed was to compare the two percentile positions achieved by a school, namely, the percentile achieved by the school on the course or achievement examination and the percentile attained by the same school on the RQ-3 test. Percentiles indicate relative positions among a group of schools.

Schools should achieve approximately to a degree that is commensurate with the mental caliber of its students. If the mental caliber of the students of a school is about average, then, other things being equal, they should as a group attain an average score on the course or achievement examination. The fullest exploitation of this evaluation method could not be accomplished because the RQ-3 test was given to students during their freshman year, therefore, it was tentatively assumed that the relative standing of the schools in the freshman year in mental ability was about the same as the relative standing of the same schools in the junior year. In subsequent surveys, a learning ability test will be administered to advanced students.

Therefore, in view of the necessary limiting assumptions which had to be made, one course examination, that of Introduction to USAF, was selected for analysis and served as an example in the evaluation of school achievement.

Bearing the specified limitation in mind, the analysis of the effectiveness of instruction in Introduction to USAF shows that:

1. The differential between course achievement and expected achievement is greatest among the top caliber schools. Every effort should be made to utilize student time to produce superior performance commensurate with their superior talents. About 50% of the schools in the top fifth on the RQ-3 test attained expected achievement.
2. About 62% of the schools in the second fifth, about 77% of the schools in the third fifth, and about 84% of the schools in the fourth fifth, attained or surpassed expected achievement.

3. As a group, the lowest group on the RQ-3 test achieved as well as may be expected.

The comparison of the course examination percentiles, and the ROTC RQ-3 percentiles cannot afford too sound a base upon which to draw definite conclusions, because the RQ-3 test was given to freshman students, whereas the course examinations were taken by junior and senior students. Yet, suggestive clues as to the effectiveness of instruction may be gleaned from comparisons of course examination percentiles and mental ability percentiles for schools where the discrepancy between these two percentiles is greatest.

The most adequate comparison of achievement and ability percentiles can be made for 112 schools which took the course in Introduction to USAF Seventeen of these schools had achievement percentiles which were 37 percentile points or more below their ability percentiles and therefore they may need to critically examine their instructional programs. For nine schools the achievement and mental ability percentiles were identical. On the other hand, seventeen schools attained achievement percentiles that were about 38 percentile points or more above their ability percentiles. These schools are maintaining superior performance. Although the method employed will provide only approximate estimates of inter-school accomplishments, its use may be considered a forward step in the direction of fairer inter-school comparison in that allowance is made for the mental ability differences that are known to exist from school to school. However, it should be remembered that achievement examinations should never be employed as the sole means to evaluate the instructor's teaching effectiveness. Other supplementary and corroborative evidence, even though subjective, should be utilized.

APPENDIX 1

EVALUATING INSTRUCTIONS IN SEVEN AIR ROTC COURSES

In future course achievement surveys when both mental ability tests and course examinations will be given to all students, evaluation of achievement in the various courses will be more exact and, hence, will give a better picture of the overall student attainment at each school. The evaluative statements as to the effectiveness of instruction in the following seven courses apply only to sub-groups of schools since more definitive data for evaluating instruction at any one school are not available at this time. The data have been presented mostly for exploratory purposes. The latter purpose will be realized if the instructors come to understand and appreciate the concept of evaluating achievement in relation to differential levels of student ability.

Evaluating Instructions in Administration and Military Management

In view of the fact that the number of participating schools which took the Administration and Military Management examination were too few to permit as intensive an analysis of results as that for the course, Introduction to USAF, a more abbreviated method of evaluation will be employed. Table 1 presents the distribution of schools on the basis of the results on the RQ-3 test and the course examination.

TABLE 1

Achievement Expectancy Placement of 55 Schools In the Upper and Lower 50% of Scores on the RQ-3 Test

		No.; Percent of Schools in Lower Half	No.; Percent of Schools in Upper Half	Total Schools
Actual Achievement Placement of 55 Schools on the Admin. & Mili. Management Examination	No.; Percent of Schools in Upper Half	12-43%	16-59%	28
	No.; Percent of Schools in Lower Half	16-57%	11-41%	27
TOTAL		28	27	55

The 55 schools were divided into two large groups, the upper half which contained schools that placed in the top half of the distribution of scores on the RQ-3 test, and the lower half group which contained schools that attained scores in the lower half of the distribution of scores on the RQ-3 test. Other things being equal, schools in the top half on a scholastic aptitute test should more often than not achieve in the top half of scores on a course examination. Of the 27 schools which placed in the top half on the RQ-3 test, 16 or 59% of them attained expected proficiency, that is, 59% also placed in the top half on the course examination. However, 11 or 41% did not attain expected proficiency, that is, 41% of the schools with abler

THIS PAGE IS DECLASSIFIED IAW EO 13526

students placed in the lower half of the distribution of scores on the course examination.

On the other hand, of the 28 schools which placed in the lower half of the distribution of scores on the RQ-3 test, 12 or 43% surpassed their expected attainment, that is, achieved scores in the upper half of the distribution of scores on the course examination. However, 16 or 57% reached their expected achievement, that is, 57% of the schools in the lower half of the distribution of scores on the RQ-3 test also achieved in the lower half on the course examination.

Evaluating Instruction in Aircraft Maintenance Engineering

Table 2 presents the distribution of schools on the basis of the results on the RQ-3 test and the course examination.

TABLE 2

Achievement Expectancy Placement of 30 Schools In the Upper and Lower 50% of Scores on the RQ-3 Test

		No.; Percent of Schools in Lower Half	No.; Percent of Schools in Upper Half	Total Schools
Actual Achievement Placement of 30 Schools on the Aircraft Maint. Engineering Examination	No.; Percent of Schools in Upper Half	7 - 47%	8 - 53%	15
	No.; Percent of Schools in Lower Half	8 - 53%	7 - 47%	15
TOTAL		15	15	30

The 30 schools were divided into two groups -- the upper half which contained schools that placed in the top half of the distribution of scores on the RQ-3 test, and the lower half group which contained schools that attained scores on the lower half of the distribution of scores on the RQ-3 test. Other things being equal, schools in the top half on a scholastic aptitude test should more often than not achieve in actual performance in the top half of a course examination. Of the 15 schools which placed in the top half of the RQ-3 test, 8 or 53% also placed in the top half on the course examination. However, 7 or 47% did not attain expected proficiency, that is, 47% of the schools with abler students placed in the lower half of the distribution of scores on the course examination.

On the other hand, of the 15 schools which placed in the lower half of the distribution of scores on the RQ-3 test, 7 or 47% surpassed their expected attainment, that is, achieved scores in the upper half of the distribution of scores on the course examination. However, 8 or 53% reached their expected achievement, that is, 53% of the schools in the lower half of the distribution of scores on the RQ-3 test also achieved in the lower half on the course examination.

Evaluating Instruction in Communications

Because the number of schools which participated in the Communications examination program were few, less refined analysis of the test results was possible. The evaluation procedure that will be employed involves the single computation of the crude percent of schools achieving the level of expected achievement. Schools which place in the top half of the range of school mean scores on the RQ-3 test should more often than not also achieve in the top half on the course examinations.

In all, 19 schools took the Communications examination. Of the top 10, that is, top half of this group of schools on the RQ-3 examination, 4 or 40% attained expected proficiency, that is, 40% also placed in the top half on the course examination; 60% of them did not. Of the lowest 9, that is, the lower half of the schools on the RQ-3 test, 3 or 33% also placed in the lower half on the course examination; the other 6 or 6% achieved in the top half on the course examination.

Evaluating Instruction in Supply

The evaluation procedure that will be employed involves the simple computation of the crude percent of schools achieving the level of expected achievement. Schools which place in the top half of the range of school mean scores on the RQ-3 test should more often than not also achieve toward the top half on the course examination.

In all, 18 schools took the Supply examination. Of the top 9, that is, the top half of this group of schools on the RQ-3 examination, 4 or 44% attained expected proficiency, that is, 44% also placed in the top half on the course examination; 54% of them did not. Of the lowest 9, 3 or 33% also placed in the lower half of the course examination; the other 6 or 67% achieved in the top half on the course examination.

Evaluating Instruction in Statistical Control, Transportation and Armament

The evaluation procedure that will be employed for these three examinations involves the simple computation of the crude percent of schools achieving the levels of expected achievement. Schools which place in the top half of the range of school mean scores on the RQ-3 test should more often than not also achieve toward the top half of the mean score on the course examination.

In all, 15 schools took the Statistical Control examination. Of the top 8, that is, the top half of this group of schools on the RQ-3 examination, 6 or 67% of these schools attained expected proficiency, that is 67% also placed in the top half on the course examination in Statistical Control.

The number of schools which took the Transportation examination was 12. Of the top 6, that is, the upper half of the group of schools on the RQ-3 examination, 3 or 50% also placed in the top half of the course examination mean scores on Transportation.

Seven schools took the Armament examination. Of the top 3 on the RQ-3 test, 1 or 33% placed in the top half of mean scores on the course examination, of the bottom 4 schools on the RQ-3 test, 2 or 50% surpassed their expected achievement and placed in the top half of schools which took the Armament examination.

Foreword

HEADQUARTERS
CONTINENTAL AIR COMMAND
MITCHEL AIR FORCE BASE, NEW YORK
25 April 1949

ConAC Manual 50-2 is published for the information and guidance of all concerned. It will be used in conjunction with the current program of instruction pertaining to Air Force ROTC Training.

BY COMMAND OF LIEUTENANT GENERAL WHITEHEAD:

H. M. TURNER
Major General, United States Air Force
Vice Commander

OFFICIAL:

HEADQUARTERS OFFICIAL CONTINENTAL AIR COMMAND

NEAL J. O'BRIEN
Colonel, United States Air Force
Adjutant General

THIS MANUAL SUPERSEDES ConAC Manual 50-200-2 Vol. II, Parts 8, 10, 11 and 14.

Preface

THIS textbook has been prepared specifically for the college or university student who is participating in the Air Force ROTC program. It is one volume of a series designed to qualify him as an officer specialist in the United States Air Force.

The text is planned to indoctrinate the officer candidate in the fundamental principles of Aerodynamics and Propulsion, Weather and Navigation and Applied Air Power, rather than to present a detailed treatise of each of these complex fields.

In order to achieve maximum efficiency and effectiveness in the performance of his duties, the Air Force officer must be constantly aware of new developments in his specialty and its allied fields. A receptive mind, nurtured by supplementary research and reading, can be a vital force in the personal and professional development of the officer specialist throughout his career.

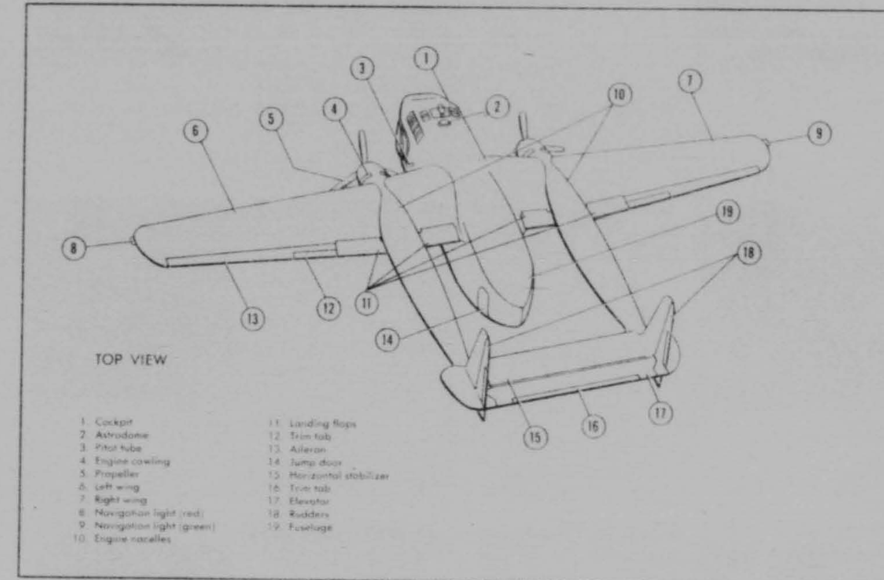
CHAPTER 1 - AERONAUTICAL TERMS AND THE AIRCRAFT



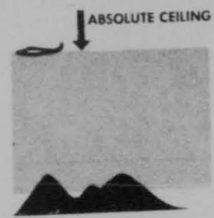
SECTION I - DEFINITION OF AERONAUTICAL TERMS

1. INTRODUCTION

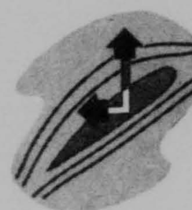
Aerodynamics is the science that deals with the aircraft and its operation. The rapid development of the Air Age has produced a vast body of knowledge related to this science, in which many fields of specialization are being perfected and explored by highly-trained experts. It includes the engineering, construction, operation, and instrumentation of all aircraft; the methods and mathematics of navigation through the air (aero nautics); and that most important of all limiting conditions,—the weather. A detailed investigation of these technical matters is certainly not the purpose here. However, an intelligent understanding of the basic principles of this vital subject must be possessed by every United States Air Force officer. It is necessary, therefore, to make a general survey of the fundamental principles, the progress and the recent developments in the science of aerodynamics.

2. GLOSSARY OF AERONAUTICAL TERMS

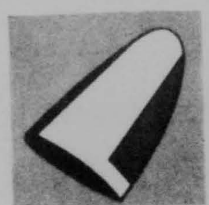
The student will constantly meet new terms connected with aircraft and aeronautics which will need clarification. The following glossary lists some of the more common terms likely to be encountered in elementary work in aviation:



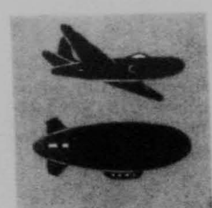
ABSOLUTE CEILING — The height above which a specific airplane cannot climb.



AERONAUTICS — The science and art of flight.

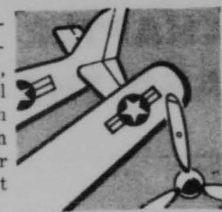


AILERON—The hinged part of the wing, usually on the trailing edge. It controls the motion of an airplane about the longitudinal axis. In other words, it controls roll.

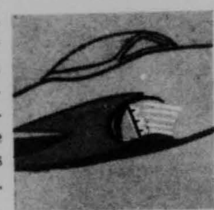


AIRCRAFT — Any weight-carrying device designed to be supported by the air, either by buoyancy or by dynamic action.

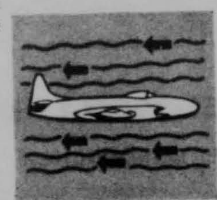
AIRFOIL — Any surface, like a wing, propeller, or rudder, which gets a useful dynamic reaction from the air. (This action results when the air strikes the airfoil at an angle.)



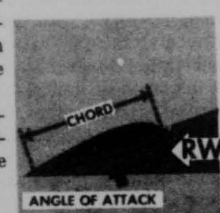
AIR SCOOP — A device for "scooping" air into the aircraft. With reference to jet aircraft it is the carefully-designed air-intake opening which ducts the air to the engine.

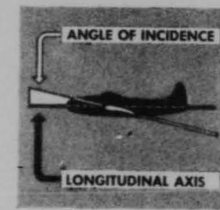


AIR SPEED—The speed of the aircraft relative to the air.

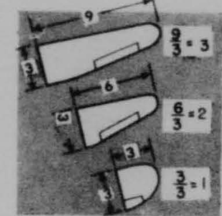


ANGLE OF ATTACK — The acute angle between the chord of an airfoil (wing) and the relative wind. (Note that the longitudinal axis is not always parallel to the relative wind.)

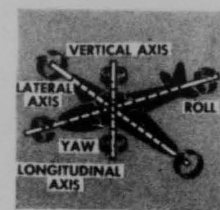




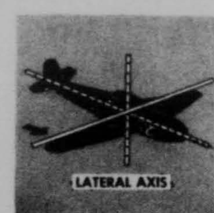
ANGLE OF INCIDENCE — The angle at which the wings are installed on an airplane. Therefore with any given aircraft, this angle does not change. It is the angle between the chord of the airfoil and the longitudinal axis of the aircraft.



ASPECT RATIO — The ratio of the span to the mean chord of an airfoil. Because most wings are not rectilinear, it is generally taken as, "the ratio of the square of the span to the total area of an airfoil."

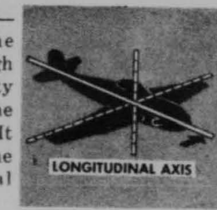


AXES OF AN AIRCRAFT —Three fixed lines of reference, each one through the center of gravity, and perpendicular to the other two.

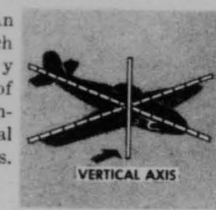


LATERAL AXIS — An imaginary line which runs through the center of gravity and is perpendicular to the longitudinal and vertical axis. Normally from wing tip to wing tip.

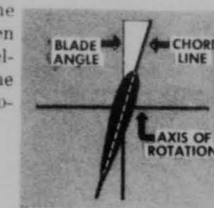
LONGITUDINAL AXIS— An imaginary line which runs through the center of gravity from the nose of the aircraft to the tail. It is perpendicular to the lateral and vertical axes.



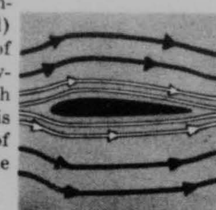
VERTICAL AXIS — An imaginary line which runs vertically through the center of gravity and is perpendicular to the lateral and longitudinal axes.



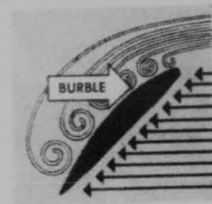
BLADE ANGLE — The acute angle between the chord of a propeller blade and the plane through which it rotates.



BOUNDARY LAYER — A layer of fluid (considering air as a fluid) close to the surface of a body placed in a moving stream, in which the impact pressure is reduced as a result of the viscosity of the fluid.

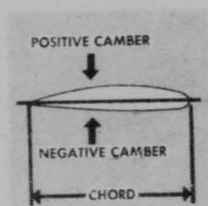


THIS PAGE IS DECLASSIFIED IAW EO 13526

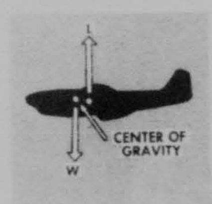


BURBLE — A term designating the breakdown of the streamline flow about a body. This occurs when an airplane reaches a stalling attitude. This is then known as the "Burble Point."

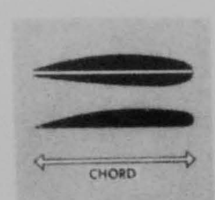
BURBLE POINT — See above.



CAMBER — The curvature of an airfoil above and below the chord line surface.

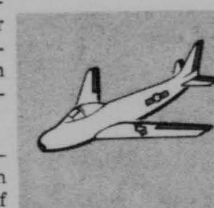


CENTER OF GRAVITY— An imaginary point in a body where the resultant of all forces of gravity is concentrated.

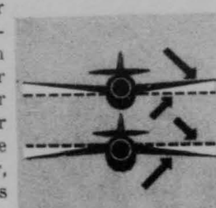


CHORD — An imaginary line connecting the leading and trailing edges of an airfoil.

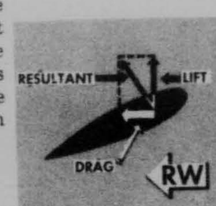
CONTROL COLUMN—A fore and aft lever with a rotatable wheel at its upper end, used for operating the ailerons and elevators of most aircraft. In fighter aircraft this column may be a "stick." Such a stick control in modern fighters is in itself a very advanced column, because in addition to its control function it also becomes the housing for such other mechanisms as the microphone button, gun button, trim tab controls, etc.



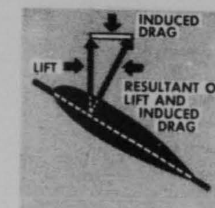
CONTROL SURFACES — Airfoil sections which control movement of the aircraft about its axes. The main control surfaces are ailerons (elevons), elevators, and rudder.



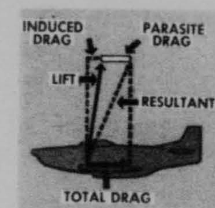
DIHEDRAL—A wing or "horizontal" tail surface design in which the tips are higher, or lower, than the center section of the wing or tail surface. Positive if the tips are higher, Negative if the tips are lower. This improves lateral stability.



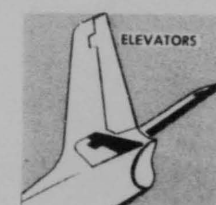
DRAG — The force which tends to resist an airplane's passage through the air. It is parallel, and in the same direction with the relative wind.



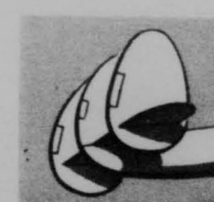
INDUCED DRAG—That drag which is created as a part of the dynamic reaction which creates lift.



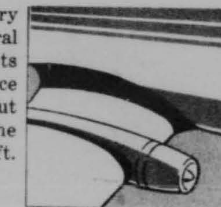
PARASITE DRAG — All drag other than induced drag is turbulence caused by such protuberances as landing gear, radio antenna, rivet heads, etc.



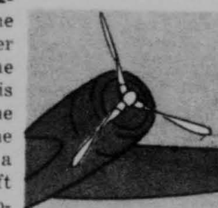
ELEVATOR—A movable airfoil hinged to the horizontal stabilizer. It controls movement about the lateral axis (pitch).



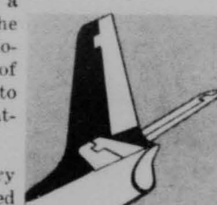
EMPENNAGE—The rear part of an aircraft, usually consisting of a group of stabilizing planes, or fins, to which are attached certain controlling surfaces such as elevators and rudders.



FAIRING—A secondary member of a structural part of an airplane; its purpose is to reduce drag by smoothing out the flow of air over the parts of the aircraft.



FEATHERING A PROPELLER — Causing the blades of the propeller to turn so that the chord of the blade is parallel with the line of flight. This is done when an engine of a multi-engine aircraft fails, to keep the propeller on the "dead" engine from wind-milling in flight.

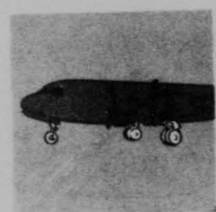


FIN—A stationary airfoil that is used as a stabilizer, such as the vertical fin that is located just forward of the rudder and to which the rudder is attached.

FLAP— A secondary airfoil that is hinged to or pivoted on a primary airfoil (usually the wing). It is used to increase the effective camber and thus increase the lift. It is also used to increase the angle of attack and thus increase the drag of the primary airfoil, for the purpose of increasing the gliding angle and reducing the landing speed.

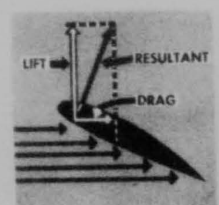
THIS PAGE IS DECLASSIFIED IAW EO 13526

FUSELAGE—The principal structure of the aircraft to which the wings and empennage are normally attached. On large aircraft it usually contains large compartments, bomb bays, etc.



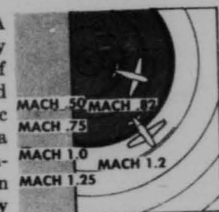
LANDING GEAR — The understructure which supports the weight of an aircraft when in contact with the ground, and which usually contains mechanisms to reduce the shock of landing. (There are many types and uses which will be discussed in a section on landing gear.)

LEADING EDGE — The part of an airfoil which strikes the air first.

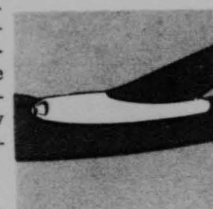


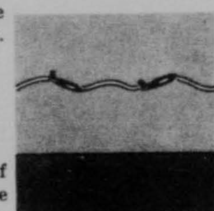
LIFT/DRAG RATIO — The numerical ratio of the lift with respect to the drag. This figure may be used to express the aerodynamic efficiency of an airfoil or of an aircraft as a whole.

MACH. NUMBER — A number determined by dividing the speed of the plane by the speed of sound. A specific type of aircraft has a certain "Mach" number, which it either can not, or can not safely exceed. The speed of sound becomes important in high speed flight because it represents the limit of compressibility of the air. If this limit is exceeded, without specially-designed airfoils, the drag increases so rapidly that normal flow characteristics no longer apply.



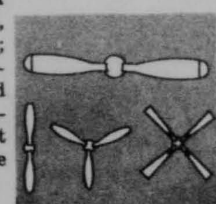
NACELLE — A streamlined enclosure built up around the engine, and its accessories, sometimes including landing gear, distinguished from fuselage because it has no empennage.

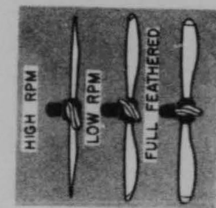




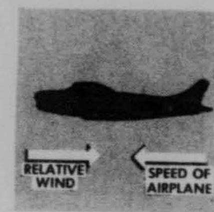
PITCH — Rotation of the airplane about the lateral axis, nose down, nose up.

PROPELLER — Any device for propelling a craft through a fluid, such as air or water; the propeller is an airfoil, and moves forward through the air because as it rotates it creates "lift," the same as any other airfoil.

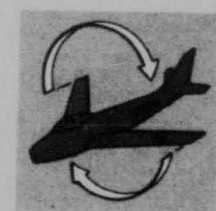




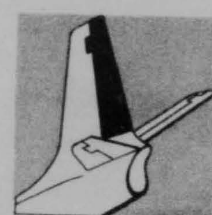
PROPELLER CONTROL — The pitch of the modern propeller may be regulated from low pitch (high rpm) through high pitch (low rpm) to the feathered (stationary) position. Some propellers may be reverse feathered.



RELATIVE WIND — Air moving past the aircraft. It is parallel to but opposite to the direction of the flight path.



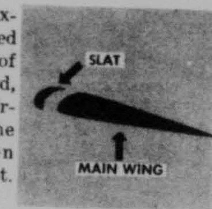
ROLL — Movement about the longitudinal axis created by the ailerons.



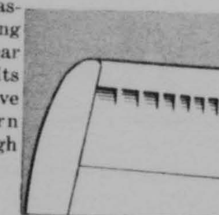
RUDDER — A moveable airfoil hinged to the rear of the vertical fin. It controls yaw.

SKIN FRICTION — The drag which results from the viscosity of the air in passing over a surface. In modern high-speed aircraft this becomes very great, and at supersonic speeds creates so much heat that the cockpit must be refrigerated.

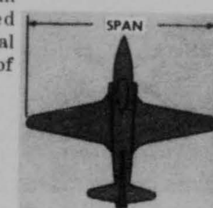
SLAT—A movable auxiliary airfoil, attached to the leading edge of a wing. When closed, it falls within the original contour of the main wing. When opened, it forms a slot. (See "slot" for use.)



SLOT—The ducted passage through a wing parallel to, and near the leading edge. Its purpose is to improve the airflow pattern over the wing at high angles of attack.

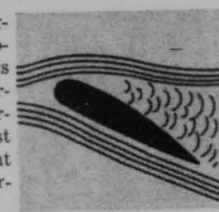


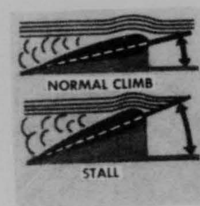
SPAN — The maximum distance, measured parallel to the lateral axis, from tip to tip of an airfoil.



STABILITY—The ability of an airplane with free controls to remain in or return to its normal flying attitude.

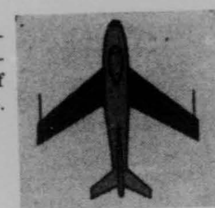
TURBULENCE — Irregular flow of air produced when air flows over an uneven surface, or when two currents of air flow past each other in different directions or at different speeds.

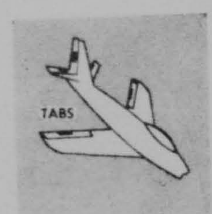




STALL — The point at which the airplane is operating at such an angle of attack that the air burbles and the lift force is insufficient to overcome gravity, and the aircraft no longer is able to maintain normal flight.

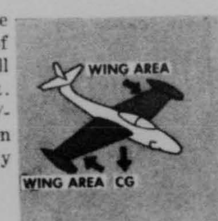
WING — The large airfoil area which develops the major part of the lift of an airplane.





TAB—A small auxiliary surface attached to a control surface for the purpose of reducing the control force necessary for in-flight stability or change of direction and for trimming the aircraft. In high-speed or very large aircraft the force required to actuate control surfaces may be so great that the pilot's control may be directly connected to the tab.

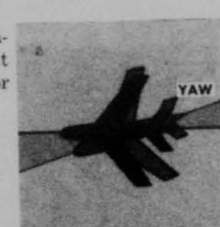
WING LOADING—The weight each sq. ft. of the wing surface will have to support. Weight of airplane/-wing area. In modern aircraft this is usually quite high.



TRAILING EDGE — The rear or following edge of an airfoil such as a wing or propeller blade.

TRIM — To adjust the tabs on the control surfaces so as to secure stability for a desired flight condition with free controls.

YAW — Angular rotation of the plane about the vertical axis, left or right.



SECTION II - NOMENCLATURE OF THE AIRCRAFT

Even though modern aircraft do not look much like the early models which were flown in the air battles of World War I, or like the Curtiss "Condor", or like the NC-4, many of the basic parts bear the same names they had then. Others, because of the evolution of aeronautics, have changed their meaning. "Conventional landing gear" once meant a type with two wheels forward of the center of gravity, and a tail wheel. Today the "conventional" landing gear is the tricycle gear as seen on the C-54, and most other modern types.

On the next few pages there are illustrations of modern aircraft tabbed to show most of the external parts. This list has been prepared to show the parts of a normal aircraft. There are many additions which could be made; but in most cases they would apply infrequently, for example: elevons, fences, tip tanks, etc. The instructor will cover any additional items.

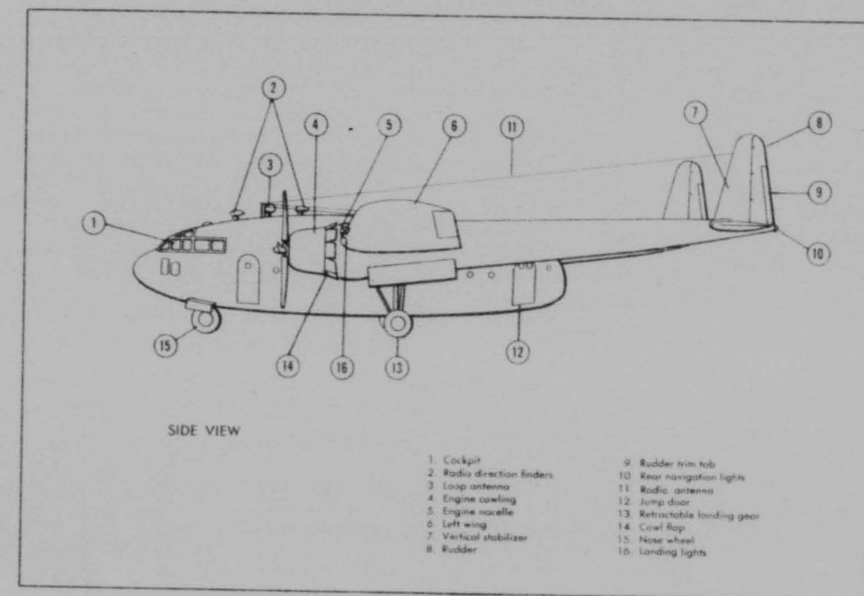


Figure 1-1 Aircraft Nomenclature—Side View

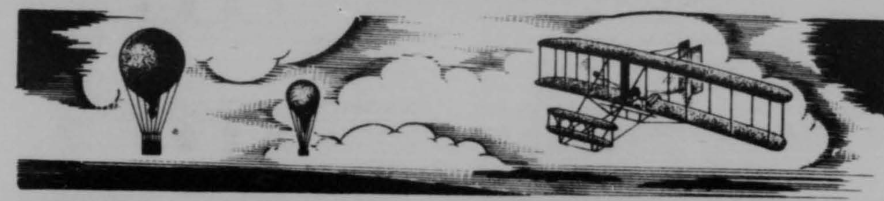
THIS PAGE IS DECLASSIFIED IAW EO 13526

CHAPTER 2 - THEORY OF FLIGHT

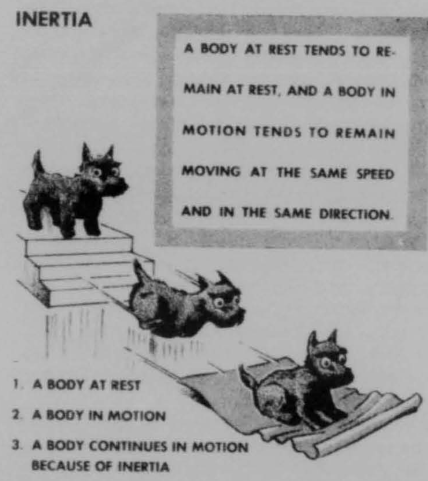


SECTION I - FORCES ON AN AIRCRAFT IN MOTION

Men had known for centuries before the first flight of the Wright brothers at Kitty Hawk in 1903 that heavier-than-air craft would fly. Toys, paper bags filled with hot air, model gliders, even model powered gliders, which had made long, successful flights, had been built. During the nineteenth century experimenters had made countless brief flights in gliders. But, lacking an adequate source of power, none of these men had been able to make a sustained flight.

With the development of the internal-combustion piston engine before the turn of the century, this necessary power plant began to evolve. The Wright brothers, in their Dayton bicycle shop, along with other experimenters all over the world, turned to the internal-combustion engine as a means of providing the necessary power to sustain flight. Already considerable data existed in the field of aeronautics from the earlier experiments of such men as Stringfellow, Pilcher, and others. But the problems involved in the theory of flight are many. Perhaps no other single field of human endeavor has been so complex or so difficult to master. The aeronaut must depend upon the work of master engineers, doctors, electronic experts, and other skilled carftsmen. Yet the basic theory itself is rather simple.

INERTIA



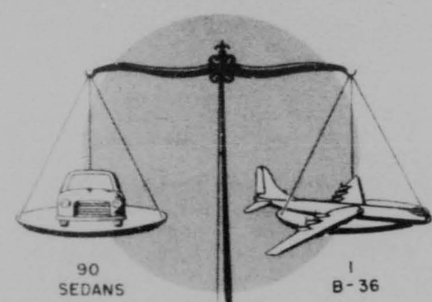
Sir Isaac Newton stated that a body at rest would tend to remain at rest, and that a body in motion would tend to remain in motion. This, of course, applies to aircraft, as well as any other body. Being at rest, an aircraft will remain at rest until the engines are started and enough power is applied to move it. How is this done?

Each engine turns a propeller. Unless we realize that the air is a fluid, which has mass, it seems as though the propellers just whirl in space. But the air is a fluid, and actually, to a fast moving body (the propeller), it is quite dense. For example; when one throws a base-ball, one has no trouble propelling the arm through the air and giving the ball a heave. However, if one stands in water up to one's chin one would have considerable trouble hurling the ball because it is impossible to move the arm fast enough under water. The water has resistance; in effect, it pushes against the arm.

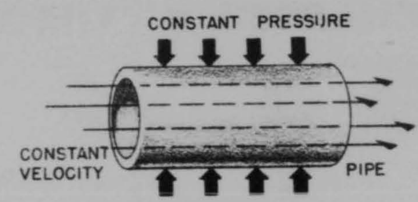
This is exactly what happens in the case of the propeller. Since the propeller is whirling much faster than the arm while throwing the ball, the air, with relation to the high-velocity propeller, has great resistance; and, in effect, it too is pushing the propeller. Again, turning to Sir Isaac Newton, we find that he stated that every action has an equal and opposite reaction. This means, for example, that, when a person walks, he pushes on the floor with a certain action; the floor pushes back on the foot with an equal reaction. One may consider what happens when it does not push back. An example would be a person stepping from the bottom of a rowboat onto the dock. When he pushes on the floor of the boat it does not react equally; and unless he is careful he will fall in the water between the dock and the boat.

When the propeller whirls fast enough so that it is pushing with great force on the air, and the air is reacting with an equal and opposite strong force, the aircraft begins to move ahead. The faster the propeller turns the harder it works and the faster the plane moves down the runway. Then at a certain speed the plane begins to fly. This brings up the next point to be considered.

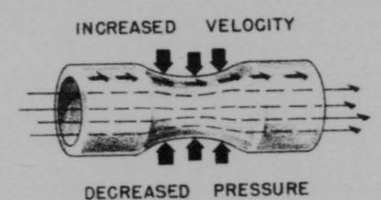
Why does an aircraft fly? How is it that a B-36, weighing as much as ninety automobiles, can rise gently into the air, and fly 10,000 miles at 40,000 feet, while the automobiles are unable to leave the ground? This time the answer does not come from Sir Isaac Newton. Instead we look into the idea presented by Bernoulli, and a few other random principles.



According to Bernoulli, the faster a fluid passes between two points, as in the case of water flowing through a pipe, the less the



pressure is on those two points. If water is forced at even pressure through a pipe six feet long and two inches in diameter the water will move through the pipe with constant speed and there will be an equal pressure at all points on the walls of the pipe. If a constriction, or throat, is made at a cer-



tain part of this pipe, the diameter at the throat will be smaller. Since the same amount of water leaves the pipe as that which enters it, what happens at this throat? Obviously the same amount must get through the smaller area; so it does the only thing possible. At the throat it speeds up. And then, according to Bernoulli, when it speeds up, the pressure on the wall of the throat decreases,—"when the velocity increases the pressure decreases."

This may be applied to flying. The air at sea level, at standard conditions of temperature and pressure, is constantly exerting a pressure of 14.7 pounds per square inch in all directions. This means that the column of air (which is a fluid mass), above any given square inch of the earth at sea level and extending to the top of the atmosphere will weigh 14.7 pounds. Therefore, this 14.7 pounds is like the pressure on the walls of the pipe in the above example; it is universal and fairly constant.

In the pipe the pressure dropped at the throat when the velocity increased. This can be duplicated in the air since air is also

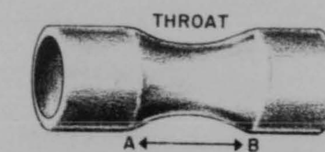
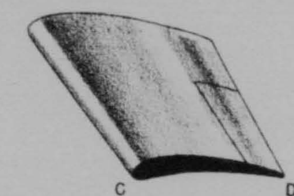
Standard Atmosphere Based on N. A. C. A. Report No. 218

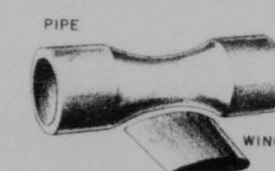
fluid. A diagram of the throat of the pipe would look like this:



The part which we are interested in, is the part from "A" to "B". We know that the part of the aircraft which creates the lift is the wing. If we were to slice the wing of an aircraft in cross section, we would see that it looks like this:

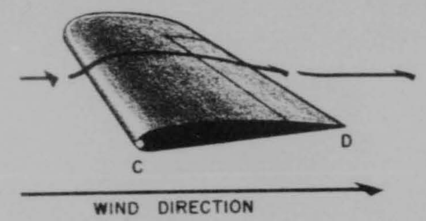


When we draw a line from the leading edge of the wing "C" to the trailing edge of the wing "D" we see a definite similarity between the curved line above the line CD and the



original pipe throat AB. The curve from CD is constructed for the same purpose. A particle of air moving from C to D, as the wing passes through it, must travel further (over the curve); therefore, it must travel faster than it would if the line from C to D were not curved. Because this air must move faster, its pressure decreases, creating an area of reduced pressure (partial vacuum) on top of the wing. Since this partial vacuum is on top of the wing, the air under the wing, which is still at 14.7 pounds per square inch, tries to move into this partial vacuum. In its at-

THIS PAGE IS DECLASSIFIED IAW EO 13526



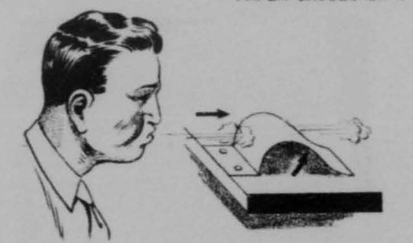
tempt to do this it presses upwards on the bottom of the wing. This lifts the wing and the aircraft leaves the ground.

This may be illustrated with a simple experiment: Take a plain piece of typewriter paper. Clear off enough of the edge of a table for this piece of paper. Now fold this piece of paper back about one inch from the end. Open this fold and place the paper on the table with the end nearest the fold near the edge of the table. It should correspond to this diagram. You will now notice that the paper from the fold (E) to the far edge (F)

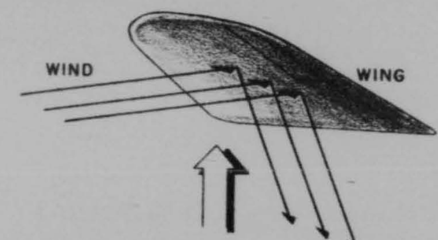
is curved like the top of the wing from C to D. Now blow moderately in puffs (not steadily) parallel to the top of the table over the top of the paper. You may be surprised to see that, instead of flattening against the top of the table, the paper tends to raise itself and, if you have a piece of soft, pliable paper it may nearly stand straight up. It is the Bernoulli idea again—high relative velocity and reduced pressure over the curve; standard pressure under the paper; the standard pressure pushes the paper up.

We have now seen where about two-thirds of the normal lift of an aircraft wing origi-

HIGH VELOCITY OVER TOP SURFACE OF PAPER CAUSES LIFT.



nates. Since the propeller also is an airfoil, about two-thirds of its lift also arises from this principle. The other one-third of the lift on an airfoil comes from the impact of the relative wind on the wing. If a flat rock is thrown across the surface of a lake, it skips along the surface as long as it maintains enough speed. Its lift comes from the force of its impact with the water. In like manner the wing of an aircraft moves through the air at a certain angle of attack: the angle of the chord of the wing to the direction of the relative wind. The wing, therefore, forces the air, which it strikes on its under-side, downwards; in turn, it is forced upwards with an equal and opposite force. These two components of lift, (1) that arising through the creation of a partial vacuum over the curved top of the wing, and (2) that amount arising from deflecting some air downwards—make up the total lift supplied by an airfoil (in this case the wing).



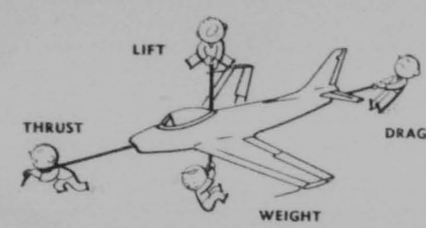
So far, two of the four forces on any aircraft in flight have been explained. The engine, through the propeller action, provides thrust, which pulls the plane ahead. This forward motion builds up the amount of airflow over the wing and creates enough lift to raise the aircraft. In direct opposition to these forces there are two others—weight and drag. Any aircraft has weight, which must be overcome by lift. Drag is the force which is the greatest deterrent to flight. Engineers have been trying for years to overcome drag in one way or another. Because air is an invisible substance it is hard to visualize the effect of drag, or to realize that the air could drag over the surface of an aircraft with so much effect that five and six thousand horsepower engines are necessary to move one fighter aircraft through the air. But this is true! Let us use the example of the effect in water again.

A person standing in water, who lowers his hand from shoulder height slowly to and into the water, feels little drag when the hand reaches the surface of the water and passes through it. However, if he lowers his hand smartly, he hits the surface with a solid slap; the harder the hand is brought down, the harder the slap. This is due to the noncompressibility of water at high speeds. The same is true in the air. At speeds up to 100 miles per hour, drag is not a major problem; but as one moves faster and faster through the air drag increases as the square of velocity. Then, when the speed of sound, the compressibility limit of air, is reached, a new set of problems arise and drag becomes the major problem of flight.

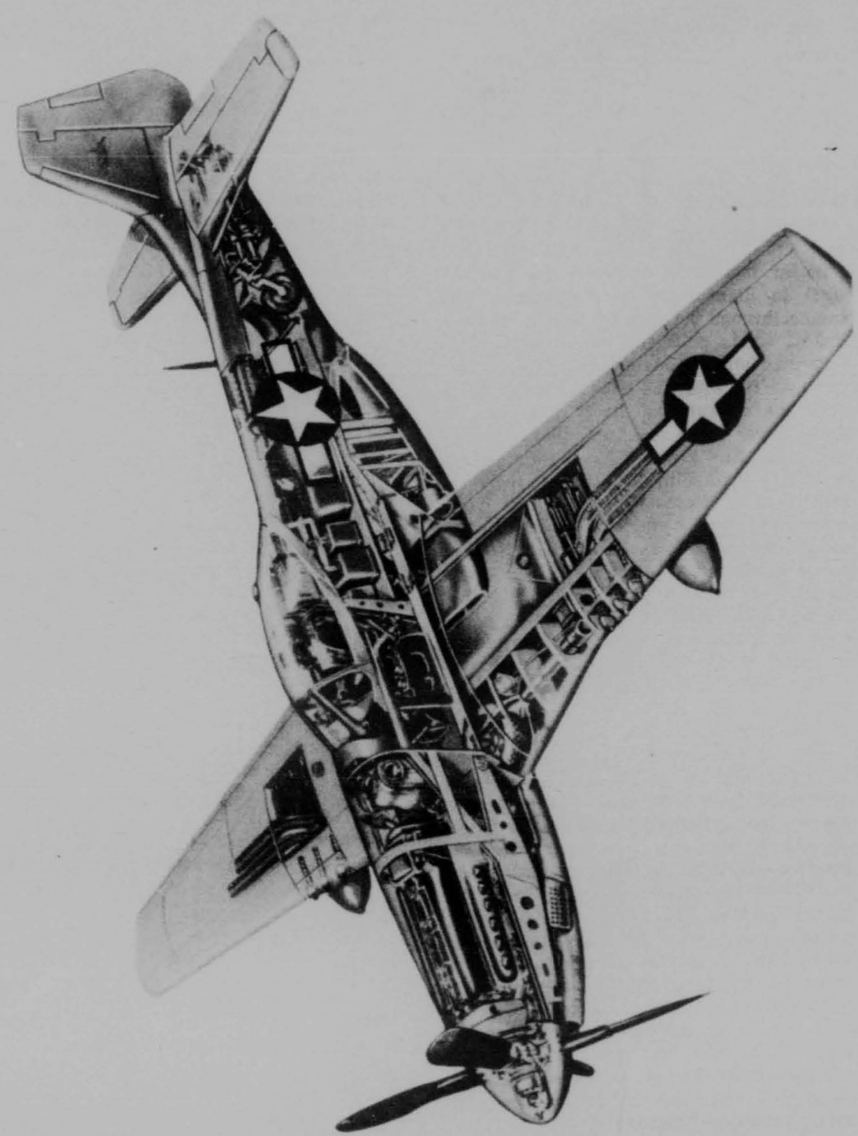
There are many kinds of drag. "Profile" drag is the resistance, or skin friction, due to the viscosity (stickiness) of the air as it passes any surface of the aircraft. This also is in combination with a "form" drag which is due to the eddying and turbulent wake of air left behind. Profile drag is just pure resistance to the movement of the aircraft through a viscous medium.

"Induced" drag, another type, is the drag component of the aerodynamic force which results from the downward velocity imparted to the air by the wing as it meets the relative wind. Its existence is unavoidable when the wing is used to create a lift force. The total drag of the wing is the sum of the profile drag and the induced drag.

Profile drag and induced drag are forces which must be accepted in part, because they result from useful causes. A third type, "parasite" drag, is sheer waste, however unavoidable. Parasite drag is caused by elements of the structure of the aircraft that do not contribute to lift. It is made up of two components: (1) skin friction, and (2) turbulence and eddying resistance. Skin friction is due to the viscosity of the air; turbulence is caused by any departure from streamline flow about the parts of the aircraft. Parasite drag is usually considered to be the sum of all the resistances except those of the wings. It includes not only the drag of the fuselage, landing gear, tail surfaces, tail wheel, and bracing, but in addition the interference drag between these parts of the aircraft. Aircraft engineers have done everything possible to reduce parasite drag. Landing gear is retracted into the wings or fuselage. All bracing is within the wing or fuselage itself—full cantilever. Nacelles are carefully streamlined, and cowling is designed to reduce



FORCES ON AN AIRPLANE IN FLIGHT



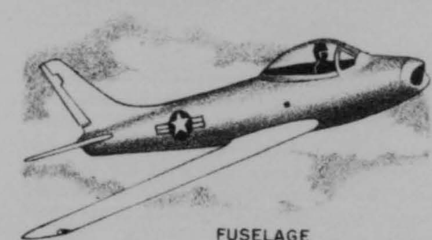
resistance to a minimum. All other protuberances are eliminated or faired into the main structure. The modern high-speed aircraft has very little parasite drag.

In summarizing the theory of flight to this point the four forces on an aircraft in motion have been discussed: (1) lift, (2) weight, (3) thrust, and (4) drag. An understanding of these four conditions of flight is the first requirement.

SECTION II - AIRCRAFT STRUCTURE

Having learned how an aircraft overcomes gravity, one may proceed to the study of how an aircraft is constructed. The aircraft is probably the most complex device constructed by man. One reason for this complexity is that it must be built to do so many things. One engineer would like to build the plane for speed, sacrificing other considerations; another manufacturer prefers to build the plane for load-carrying ability; a third wants safety, and so on. The final aircraft must represent a compromise. One often hears people ask: "Is the F-84 better than the F-80?" There is no direct answer to any of these questions. Each aircraft is built to meet certain desired specifications. Like the knife, fork, and spoon, neither is better than the other in general; one is better than the other for a specific use, i.e., the knife for cutting; spoon for soup; fork for solid foods. And so with aircraft. The B-36 is a splendid long-range, high-altitude bomber; the F-86 is a good, high-speed, medium-range fighter, etc. Each has its own utility.

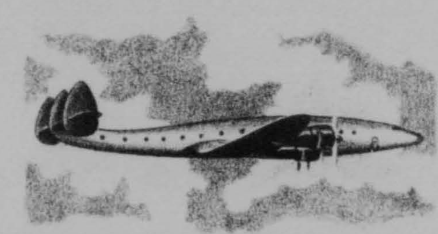
When specifications have been laid down for a certain type of aircraft, designers seek to create a product which will best fulfill all requirements. First of all lift must overcome weight, and thrust must overcome drag. The two most important parts of the aircraft are readily seen to be the powerplant and the wing. The powerplant will be discussed in a following section.



FUSELAGE

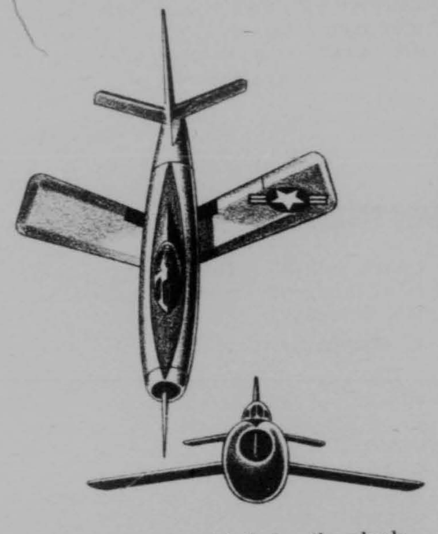
1. FUSELAGE

The wing is the primary lift surface. All lift does not come from the wing; but, as the "flying wing" type of aircraft ably demonstrates, the wing could function as an entire airframe itself. The tail section, empennage, of an aircraft carries a certain amount of the load, but it is primarily a stabilizing implement. In some cases the fuselage itself is designed along airfoil lines, and does provide direct lift to the aircraft.



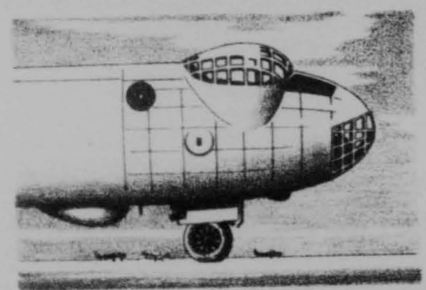
The Lockheed "Constellation" (C-121) has a "humped-back" fuselage. This is due to the fact that the top of the fuselage is curved to the same airfoil specifications which were originally used on the upper wing surface of the very successful P-38 "Lighting" of World War II. Some modern fighters incorporate "fuselage" lift into their design, but further discussion on this feature may be omitted because it is not generally used.

The normal fuselage is not a lift device. On a modern fighter like the F-86 the fuselage must house the pilot, engine, radio equipment, guns, much of the fuel, a large



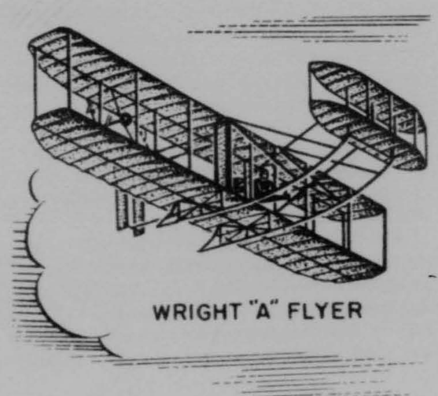
air scoop and exhaust tail pipe, the wheels—in fact almost everything—because the high-speed thin wing of that fighter is too small to have room for anything. The fuselage, then, is a necessary body cleanly streamlined over all these items and designed to afford as little drag as is possible.

Bombers and transports have an entirely different type of fuselage. It is justly called the "cabin." Today it might even be called the "the village." The fuselage of he B-36 is nearly 200 feet long (two-thirds of the length of a football field). In this fuselage there are four bomb bays, two large enough to serve as hangars for parasite fighter aircraft (F-85 type). The forward compartment is for the pilots, engineers, navigators, bombardiers, radar operators, and their equipment. Connecting the forward compartment and the center (fire-control) section is an 85-foot tunnel with a dolly for carrying a crew member from one end to the other. Far in the rear is the tail gunner's domain. This tremendous fuselage is the major bulk of the B-36. Aerodynamically it is one huge source of drag which must be overcome by the engines. Designers do what they can to streamline and reduce the size of the fuselage; but they can not exceed specified requirements.



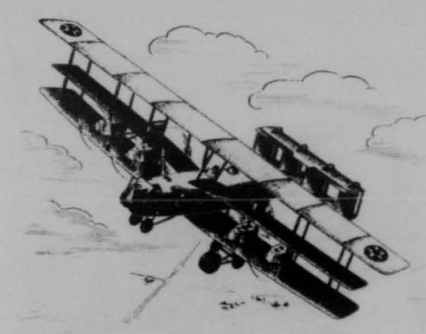
2. WING

If the details of fuselage construction seem limiting, study of wing characteristics show that those problems are relatively insignificant in comparison. The Wright brothers found out that the wing must do more than deflect air downward with its lower surface; so they warped the wing of their "flyer."



WRIGHT "A" FLYER

Through years of experimentation and development, wings became thicker and more curved. Early aircraft had several parallel wings. There were biplanes, triplanes and even quadriplanes. Because of the inability of manufacturers to build internally-trussed wings, these multiwinged aircraft were held together with wire and struts.



Barling Triplane, 1923.

As speeds increased it became imperative to cut down on this external construction, which was creating considerable drag. Also, as speeds increased, the air flow over one wing began to interfere directly with the air flow over another, and interference drag became an important concern. This eventually led to the monoplane with full cantilever construction. The monoplane was the answer to the elimination of most of the interference drag, and the cantilever construction permitted clean surfaces. But by the time the airframe had reached this stage of development power-plant manufacturers were putting out engines which were capable of driving the aircraft faster and faster. The design of the single wing itself had to be modified.

Wing Development

There were two general channels of development which could be pursued in order to change the planform of the wing. The first was to change the "aspect ratio." Aspect ratio is the ratio of the span to the mean chord, and is determined mathematically by dividing the span squared by the wing area.

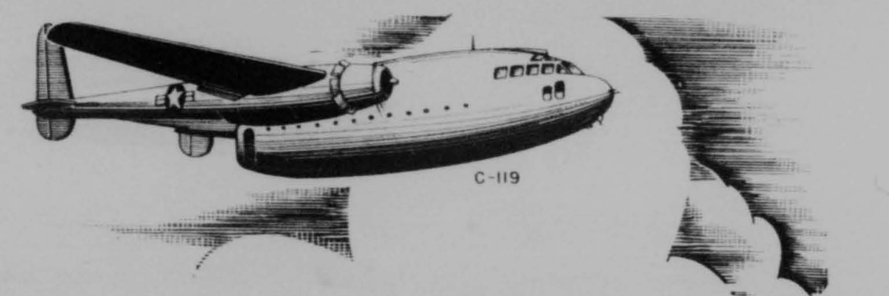
A second system of changing the plan form of the wing is by "tapering" the wing. This has led further to such innovations as "swept-back" wings, and "swept-forward" wings, "inverse" tapered wings and "delta" wings.

The airfoil cross-section of the wing itself has changed with the increase in speed. At first airfoils were curved on top and on the bottom. (Figure 2-1.) Later the bottom of the wing was kept straight and the upper surface was curved higher. (Figure 2-2.) Then as aircraft were constructed larger and larger (B-24 for example), the wing curve was increased considerably to support the heavy load on a relatively small wing area.

High Speed Wings

At the present time, with the advent of jet powered aircraft, aircraft capable of very high speeds, wings had to be designed which slit the air cleanly on the "laminar" flow pattern (Figure 2-3). The center of lift was moved further back, and the leading edge of the wing was made knife-like. Furthermore, with present aircraft approaching the speed of sound, and with the actual air-flow over many airfoil curves already at sonic or supersonic speeds, even though the airframe itself may be below Mach 1, wing design must become more and more critical. Very high speed wings are thin, usually swept-back, and knife like.

This creates other problems in wing construction. The landing gear, fuel cells, arma-



THIS PAGE IS DECLASSIFIED IAW EO 13526

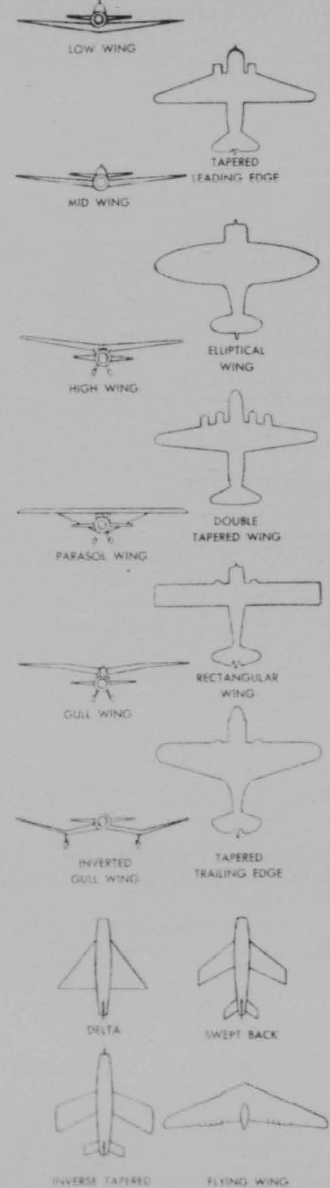


Figure 2-1

ment, and engine nacelles were in the wings of most World War II aircraft. The new thin and stubby design changes this conventional plan. On some new planes, and undoubtedly on most future ones, the landing gear and armament will have to be fitted into the fuselage. Jet engines lend themselves readily to wing-root or fuselage mounting, because they require no propellers. And, because the wings are thin and small, even the fuel cells must be in the fuselage, with auxiliary tanks on the wing tips.

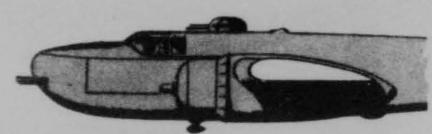

Figure 2-2

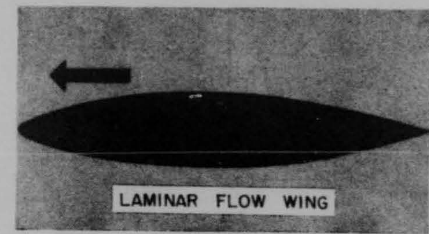

Figure 2-3

Wing Loading

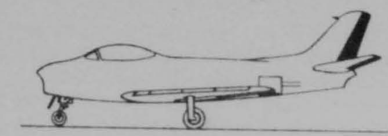
Throughout this evolution of the wing another factor has been changing—the wing loading. Formerly the weight per square foot of wing surface was quite low—less than 20 pounds per square foot. Until a few years ago a wingloading of 39 pounds per square foot was regarded as maximum. Today, with the use of high-lift devices, wing loads of over 60 to 1 are not uncommon.

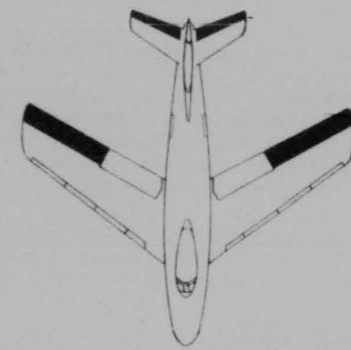
3. CONTROL SURFACES

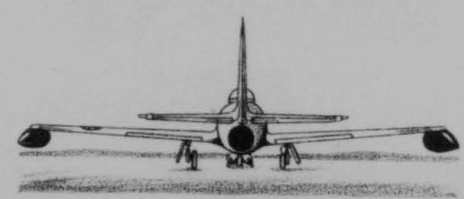
Ailerons (Elevons)

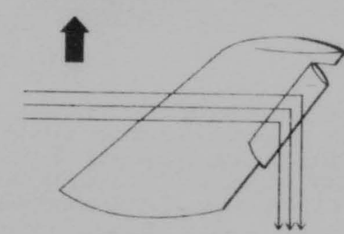
The main part of the wing provides lift, but on each wing there are other surfaces—control surfaces, and lift/drag devices. The principal control surfaces are the ailerons, elevators, and rudder. The aileron is a hinged, movable portion of the trailing edge of the wing, usually near the wing-tip. Its purpose is to change the airfoil characteristics of the wing to increase, or decrease, lift in order to raise or lower the section of wing to which it is attached. The two ailerons are rigged to work in opposite directions. When one raises the right wing, the other lowers the left wing. This causes the aircraft to bank which results in a turn to the left.

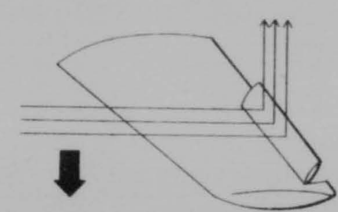
It was stated earlier that the greater the curve on the surface of the wing the more lift this wing will create. Therefore, when the aileron is lowered it increases the curve, therefore lift, of that section of the wing. While one aileron is lowered, the other is raised. This raised aileron becomes a drag device which spoils the lift of that wing sec-





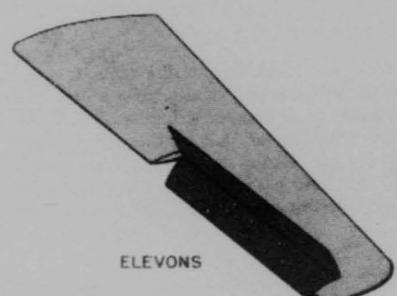






tion causing it to lower. In level flight the ailerons trail, and fit into the normal wing section creating neither lift nor drag. In high-speed flight it is necessary that the boundary layer of air flow smoothly over the entire wing surface. On some wings the ailerons have been slightly "cusped" to aid this flow of boundary-layer air. This, in turn, creates a strong pressure area which tends to hold the aileron in the "trailing" position. This pressure at times may be so great that the pilot would be unable to actuate the aileron controls with an unassisted lever. Some jet aircraft have incorporated a system of hydraulic or mechanical boost to aid the pilot.

Such problems have caused engineers to try other means of achieving lateral control. On many new aircraft they are using el-



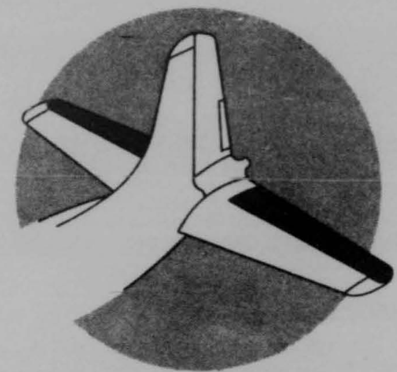
evons. Elevons perform the function of the aileron by creating drag on one wing, causing it to drop. In general, elevons are flat surfaces which are raised or lowered (or both) from the normal surface area of the wing.

Elevator

The second control surface is the elevator. The elevator is attached on the trailing edge of the horizontal stabilizer. When it is raised, it forces the tail of the aircraft down; when it is lowered, it forces the tail up.

Rudder

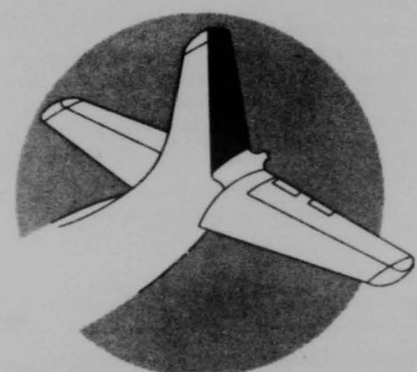
The third control surface is the rudder. It is attached on the trailing edge of the vertical stabilizer. The rudder is moved left or right. When it is moved to the left it



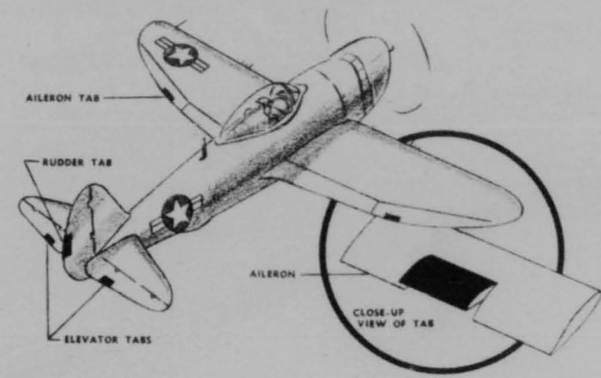
forces the tail to the right turning the aircraft to the left. In normal flight it trails the stabilizer.

4. CONTROL TABS

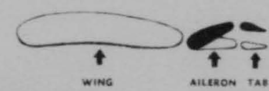
Because the forces of high speed flight are so great, and because some modern aircraft are so large, it requires considerable force to actuate these control surfaces. As a result greater use is being made of control tabs. A tab is a small surface attached to the trailing edge of the normal control surface. This small surface is moved by a fixed control which sets it at the desired angle with respect to the control surface itself. When the tab, for example the rudder tab, is moved to the left, it will force the rudder to the right (by virtue of the dynamic force of the impact of



TRIM TABS

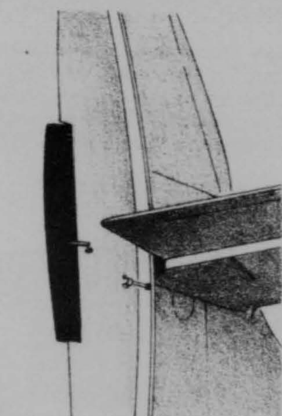


THE LOCATION OF TRIM TABS



OPERATION OF TRIM TAB

relative wind over the tail of the aircraft). By forcing the rudder to the right, it causes the tail of the aircraft to be moved to the left. When the empennage is moved to the left, the aircraft moves to the right. This same chain of events occurs with respect to



the elevator tab and the aileron tab.

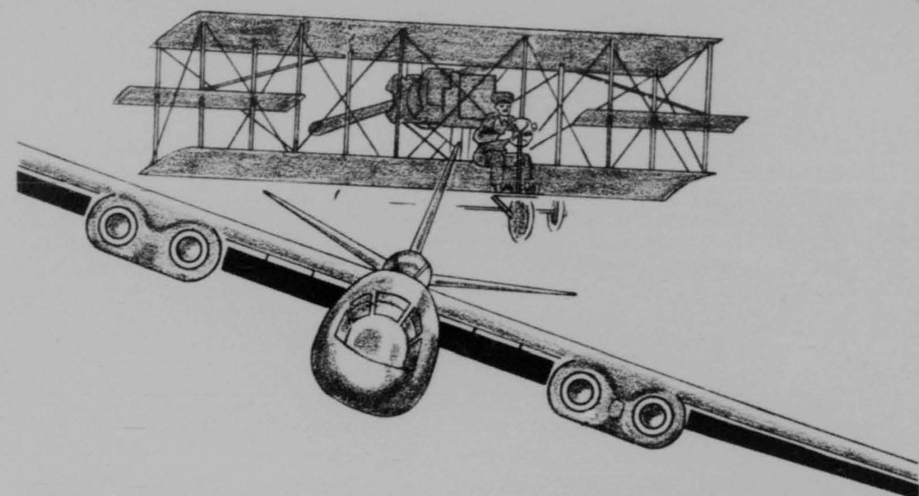
This is not the only use of the tab. It is perhaps not even its principal use. Tabs are primarily used to trim the aircraft in "straight-and-level" stabilized flight, which will be discussed in a later section.

5. HIGH LIFT DEVICES

The wing loading of modern aircraft has increased to such a point that it is, in some cases, as high as 65 to 1. This can be aerodynamically sound as long as the aircraft maintains high speed at all times. However, the normal aircraft must conform to current operational requirements of run-way length and landing speeds. A high wing loading means that aircraft must land at very high speed unless something is done to increase lift at lower speeds. This is done with the use of flaps and slots.

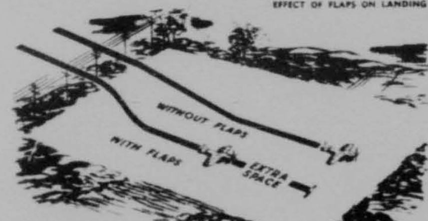
Flaps

Conventional Flaps. Flaps are airfoil sections at the trailing edge of the wing. They add to lift by increasing the wing area and

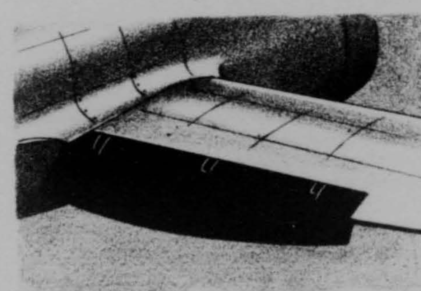


its airfoil curve. They also increase drag considerably. Flaps have been very useful on conventional aircraft for the purpose of reducing landing speed, and increasing the rate of descent.

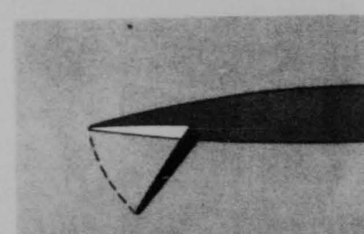
EFFECT OF FLAPS ON LANDING



There are three common types of flaps. The conventional flap is a rear section of the wing itself which is hinged and may be lowered. This large, flat surface lowered at an angle of 50 to 70 degrees produces considerable drag which spoils the lift of the airfoil and permits the aircraft to glide to a landing at a very steep angle. When the flaps are lowered 25 to 35 degrees they extend the curve of the airfoil enough to create additional lift. This permits the aircraft to land at a slower air speed than would be possible without flaps.

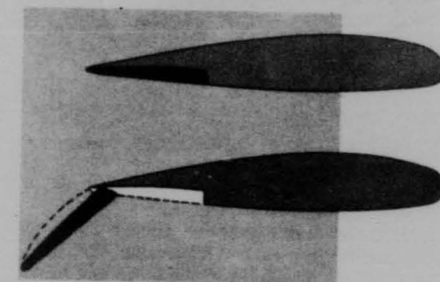


Split Flaps. Conventional hinged flaps were found to create a higher ratio of drag to lift than was desired on some type airfoils; so split flaps were devised. The lower section of the wing is the only part which is hinged,



and the trailing edge splits. This type of flap does not alter the upper airfoil curve of the wing; but it does provide the same amount of drag as the conventional flap.

Fowler Flaps. Some aircraft, especially heavy aircraft, need to gain considerable lift in order to slow down before landing. Fowler

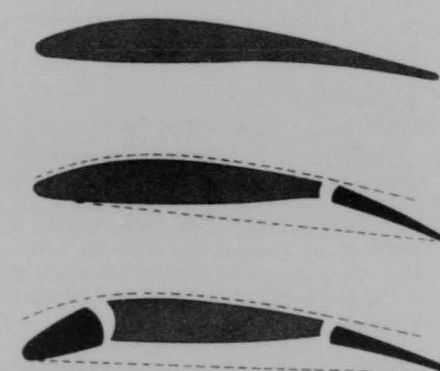


flaps have been constructed to do this. They combine the features of normal flaps and split flaps. Fowler flaps are a type of split flaps. The flap (lower) portion of the wing moves backwards on guides without lowering from the wing. The rearward movement of this large surface, first of all, adds to the wing area itself. Then, after the flap has begun to move to the rear it is guided downwards and farther back. Fowler flaps may be lowered as much as 70 degrees from the chord line; and, because they increase the area and airfoil curve so much, they increase total lift considerably. They represent the most useful high lift/drag device available at present.

Certain advances in modern design have had an important effect on flap design. The old, familiar DC-3 (C-47) uses the split flaps. To increase the flap area, the section was continued under the fuselage from wing-root to wing-root. This innovation gave the DC-3 a long flap area extending unbroken from aileron to aileron.

The increase in size and number of engine nacelles has made it necessary in many large aircraft to hinge the lower rear section of the nacelle so that it may be lowered with the flaps, as an integral part of the flap.

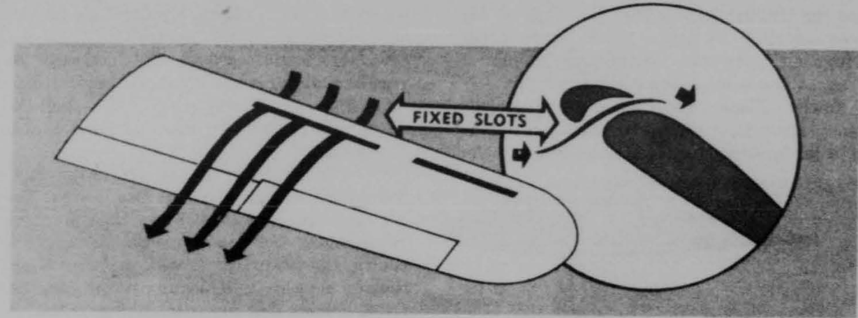
Furthermore, since flaps are now so necessary for high wing-load aircraft, the total area of the flaps must be increased. This has led to the development of flaps from wing-tip to wing-tip, which consequently blocked out the area conventionally assigned to the aileron. This has been another reason behind the development of the elevon as a lateral control. The elevon works as efficiently in



BASIC AIRFOIL (THIN, HIGH-SPEED WING)

DOTTED LINES SHOW EFFECTIVE CAMBER WITH TRAILING EDGE FLAPS PARTIALLY DOWN.

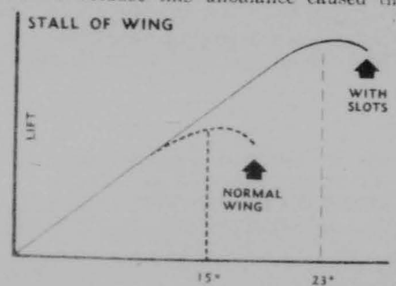
DOTTED LINES SHOW EFFECTIVE CAMBER WITH BOTH LEADING EDGE AND TRAILING EDGE FLAPS PARTIALLY DOWN.



the center of the wing as it does at the trailing edge, and therefore lends itself as a suitable substitute for the aileron.

Leading-edge Flap. A major function of the wing flaps is to increase the airfoil curve of the wing. Research during the past several years has shown that a leading-edge flap would also increase lift, because it, too, would increase the forward part of the airfoil curve. The F-86 has these leading-edge flaps. This consists of a section of the leading edge of the wing which may be moved forward and downward in the same manner as the Fowler flap.

Flap Control. Flaps are used for both landing and take-off. They are sometimes used in flight. Their effect is so great on the flying characteristics of the aircraft that a very efficient control and activating system must be employed whether it be electrical, pneumatic, or hydraulic. One of the early weaknesses of flap operation was that the system would not always "balance", i.e., one flap (left or right) would come down before the other one. The results were sometimes disastrous because this unbalance caused the



plane to roll over. This "balancing" of flaps is now well regulated.

Slots. Leading-edge flaps appear to be a refinement of an early device called the wing "slot." The slot is built in the wing just back of the leading edge a few inches, and extends along the wing, usually in the outer section. It is cut through the wing from the lower surface to the top. During normal flight it plays no part in the over-all airflow pattern; but as the wing approaches the stall angle it permits air to flow through behind the leading edge, improving the low-speed characteristics of the wing.

Slat. In some cases, principally on small low speed aircraft, a slat is built into the leading edge of the wing, which automatically moves out in front of the wing when the wing approaches a stall. By moving out ahead of the wing the slat performs the same function of a slot.

6. LANDING GEAR

Evolution of the Landing Gear

The Wright brothers had few problems when it came to devising a landing gear. For a light, low-speed aircraft a pair of skids was a satisfactory solution. For today's fifty-ton 600 mile-per-hour bomber, with its swept-back, thin wings the problem of designing a light, but strong, landing gear is very complex.

As aircraft speed and weight increased the skid became impractical. It was replaced by a pair of wheels placed side by side ahead of the center of gravity of the aircraft. For many years thereafter the empennage was supported by a tail-skid, which in turn was

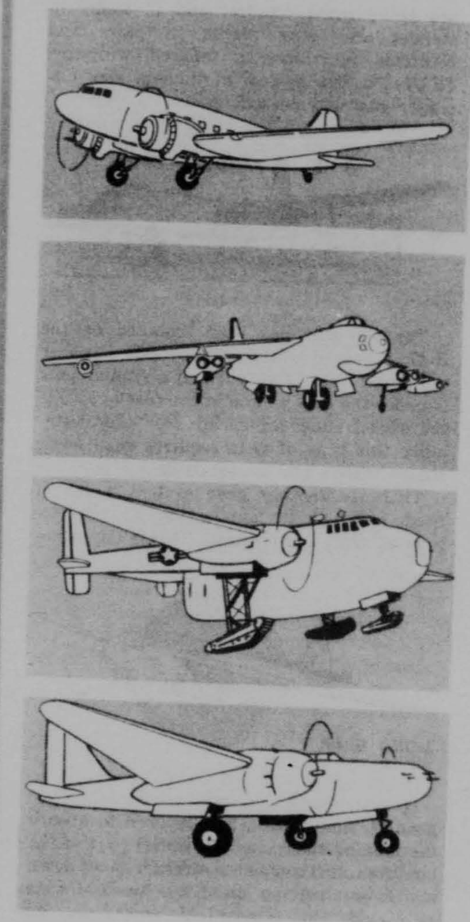


Figure 2-4

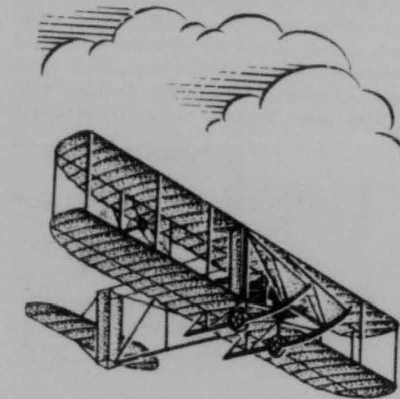
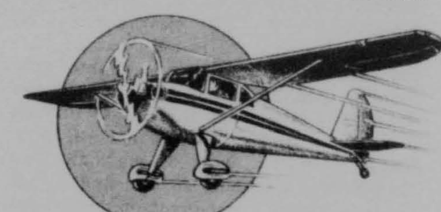
replaced by a 360 degree swivel tail-wheel. This arrangement became standard on all land-based aircraft for so many years that it became known as the "conventional" type of landing gear. (In this chapter it will not be possible to cover the details of landing gear construction. The discussion will be limited to the type of gear.) The landing gear



had to be rugged enough to sustain the shock of ground contact, and high enough to keep the propeller from striking the ground when the tail was raised during the take-off run.

Then as aircraft speeds increased and drag became a major factor, the wheels of the plane were faired over with "pants" to streamline them, and the landing gear struts were inclosed in a smooth sheath. The next



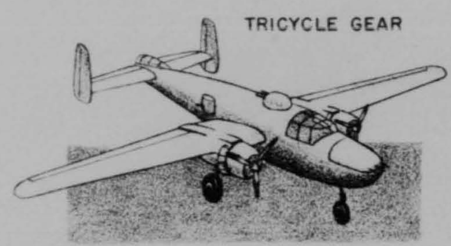
FIXED GEAR

change was the development of retractable landing gear. This was a major advance in aircraft engineering, because it completely eliminated the considerable drag created by the landing gear. It was a few more years before the tail wheel was made retractable. This eliminated all landing-gear drag.

Just before World War II new aircraft were designed with the main gear behind the center of gravity, and with a small wheel under the nose of the plane. The earlier, conventional gear had employed three wheels; but in spite of this, the new system became

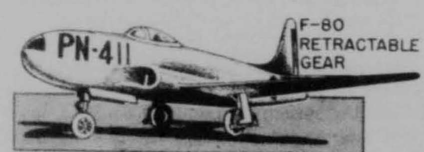
941720 O - 51 - 3

popularly known as "tricycle" gear. In many ways this was a big improvement over the conventional type of gear. First of all, the fuselage was now level with the ground at all times. It also made landing easier, especially cross-wind landings. Before long, tricycle gear became more conventional



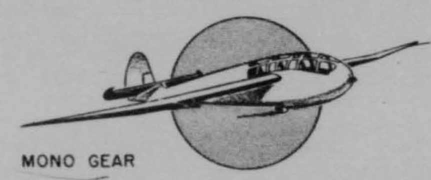
than the old system. Nearly all present aircraft utilize this system. At first it was necessary to build the tricycle gear quite high because high-power engines utilized very long-bladed propellers which had to be kept above the ground with enough margin to take into account tire failure and the 10 to 15 inch drop on the blow-out side. This high, complicated gear added considerable weight to the air frame itself.

With the advent of jet propulsion engineering for propeller clearance was no longer necessary. It meant that on jet-propelled aircraft a shorter and lighter gear could be used. But before aircraft designers could relax as a result of this easy solution to a major problem, a new one began to plague them. The wing of the high-speed aircraft was becoming so thin and so far swept-back that it was becoming almost impossible to retract the wheels into the wing. (Originally, in an effort to broaden the base of the gear so that landing an aircraft would be easier and to prevent interference with the bomb bays in bombers, the wheels were put out in the wings.) This problem is currently being met in three ways: wheels are being retracted into the fuselage; wheels are being made smaller, and in some instances are being placed in pairs and retracted into inverse, tapered wing-tips (F-91); a new system of tandem and outrigger gear has been devised.



Tandem gear has been installed on the B-47. A pair of wheels, side by side, is under the nose of the fuselage; and a similar pair is under the rear section of the fuselage (like the wheels under a bicycle). For lateral stability this type of gear requires small, outrigger wheels under each wing.

There is another gear system which is used, although its application on heavier-than-air craft is infrequent. This is the mono-



gear. A small nose-wheel is used to absorb the landing shock and the initial part of the landing roll. Then as the aircraft slows down and loses all flying speed the fuselage rests on a skid. This is adaptable so far only on light aircraft. With weight and space considerations so important today in aircraft design, it is possible that heavier aircraft might adopt this system. The nose-wheel would sustain the impact of landing and the actual landing on a keel skid would not be hazardous.

This leaves the evolution of the landing gear where it started, because the mono-gear is only once-removed from the skid itself.

7. AIRCRAFT STABILITY

Definition

An acceptable aircraft must be stable in flight. This may be defined as the tendency of an aircraft to return, without the aid of the pilot, to a condition of steady flight when it has been disturbed. There are two general classes of stability: static stability and dynamic stability.

Static Stability

An aircraft is statically stable if, when disturbed from a condition of steady flight, an unbalanced force is automatically set up in the proper direction to return it toward its original attitude of steady flight. The airplane is statically unstable if the unbalanced forces direct it still further from the original attitude. If no unbalanced forces are set up, the aircraft is said to have neutral static stability.

Dynamic Stability

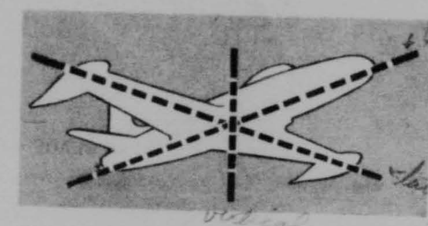
When a statically-stable aircraft is disturbed from a condition of steady flight, it is restored to its initial attitude by a built-in force. Ordinarily, this force will carry the plane beyond its original attitude. Then, since it is statically stable, a force will be set up in the opposite direction, causing the aircraft to swing back again. This may be repeated several times, the aircraft oscillating past the neutral position with a motion similar to that of a pendulum. If these oscillations die out and the airplane returns to its original condition of steady flight, it is dynamically stable. If the oscillations increase in magnitude, the aircraft is dynamically unstable, and if the oscillations continue unchanged, the aircraft has neutral dynamic stability.

It should be noted that dynamic stability is dependent upon static stability; that is, if it is statically unstable it will not have the opportunity to demonstrate whether or not it is dynamically stable, since the forces necessary to produce the oscillations will never be set up in a statically-unstable aircraft. An aircraft may be statically stable and dynamically stable, or it may be statically stable and dynamically unstable.

Stability is essential in any aircraft. An unstable plane may be flown all right; but it will require constant control. A stable aircraft, however, will remain steady in level flight, without the necessity of constant control; furthermore, if deflected from level flight by a gust of wind, a stable plane will return to level flight itself without requiring that the pilot apply sudden correction.

Axes of An Aircraft

An aircraft has three axes, and all motion of the aircraft is around one or more of these



axes. The lateral axis is along a line from wing-tip to wing-tip through the center of gravity. Motion about the lateral axis is called "pitch," and is controlled by the elevators. This lateral motion causes the plane to climb or descend.

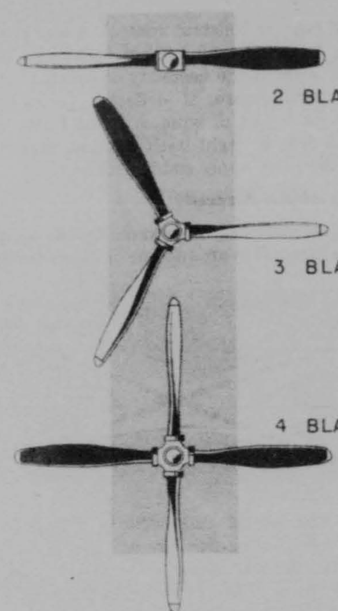
The longitudinal axis is along a line from the nose to the tail through the center of gravity. Motion about the longitudinal axis is called "roll," and is controlled by the ailerons or elevons. Longitudinal motion causes the plane to turn right or left.

The vertical axis is along a line drawn vertically through the center of gravity and perpendicular to both the longitudinal and lateral axis. Motion about the vertical axis is called "yaw," and is controlled by the rudder.

8. PROPELLERS

We have already mentioned that a propeller is an airfoil, and as such it sets up forces the same as any other airfoil. When the Wright brothers were planning their aircraft, they tried to find out if any scientific data existed governing the use of propellers. They found that for aircraft propellers there was no reliable data. They even turned to scientific data on steamship propellers and found that there was almost nothing on this subject. Because of this lack of material on

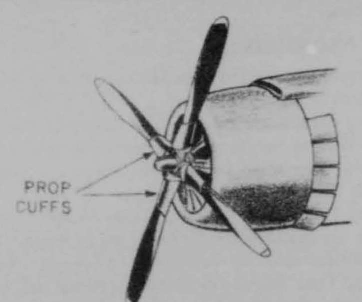
THIS PAGE IS DECLASSIFIED IAW EO 13526



TYPICAL PROPELLERS

propellers, they had to start from scratch and work out their own experimental types. Beginning with these experiments the development of the aircraft propeller has been as spectacular as the development of the aircraft itself.

The function of the propeller is to provide thrust. It does this in the same manner that any airfoil functions. In addition to creating thrust, the propeller is used in some cases to aid in cooling the engine. Cuffs are added to the inner portion of the blade to increase the volume of air passing over the engine. The propeller also forces a flow of air over the tail surfaces which is a help in taxiing and low-speed flight.



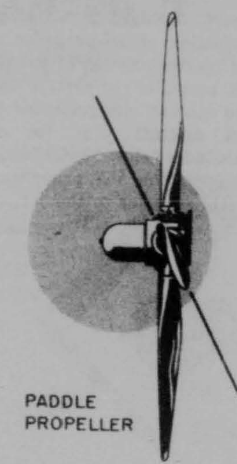
There are many types of propellers. A one-bladed propeller is efficient but has not been adapted for general usage. During the first three decades of powered flight, the two-bladed propeller was the conventional type. Then as engines became more powerful, longer and larger propellers were required. Because the length of the propeller blade must be limited by the length of the landing gear, height of the engine above the ground, etc., an alternative to the long-bladed propeller was required. This led to the use of three, four, and even five-blade propellers, and also to the use of contra-rotating propellers. Each of these new designs was evolved to utilize the increase in power of new engines.

The length of the propeller blade was not limited entirely by the landing gear, etc., but by the fact that the longer the blade, the faster the tip speed is. As this speed approaches the speed of sound, the tip, like any other airfoil, is affected by compressibility shock waves which reduce its effectiveness appreciably. A shorter, multi-blade propeller does not reach this sonic barrier as rapidly as the longer blade propeller.

For many years it was believed that the tip of the propeller should be tapered. Until the end of World War II most conventional blades were tapered. However, during the war the paddle-propeller became familiar, and following this development the square-tip propeller became widely used. This square-tip blade is most efficient with high-power engines for high-speed and high-altitude flight.

Conventional propellers have all been straight from tip to tip. But recently a swept-back type has been designed. It has been developed for near sonic-speed operation.

Most propellers are in front of the engine to which they are attached; but on some aircraft, notably the B-36, the propellers are mounted in the rear. These are called "pusher" propellers. The advantages, on the B-36 especially, are that the engine may be com-



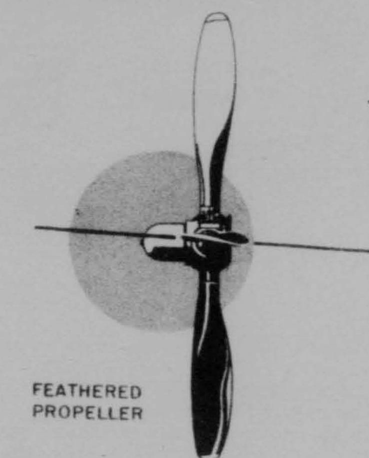
pletely housed inside the wing, and the leading edge of the wing is unobstructed by the nacelle.

No aircraft propeller would be efficient on planes flying over 100 to 150 miles per hour, without controllable pitch. Without going into detail, the reasons for this have to do with the idea of the efficiency of any airfoil with respect to its angle of attack. A fixed propeller has a certain, built-in, angle of attack. As the speed of the aircraft increases, this forward motion changes the effect of this built-in angle of attack relative to the mass of air through which it is moving. An increase in forward speed increases the angle of attack; and, as we know, the angle of attack is limited by the stalling angle. At this point the propeller loses efficiency. To cope with this situation controllable-pitch propellers have been developed.

The simplest controllable-pitch propeller is the two-speed type. It has two speeds, one for low-speed operation (take-off, climb, and landing); the other, for high-speed operation (normal cruising). This type is an improvement over the fixed-pitch propeller; but it too has limitations.

These limitations were overcome by the fully-controlled, constant-speed propeller. By means of mechanical, hydraulic, or electrical power the blade of the propeller may be set to rotate at a constant rpm regardless of the speed of the aircraft or the power applied. This gives the pilot full control over the propeller. He may move the propeller from its top rpm limit, around 2800 rpm, to full-feathering.

The ability of the modern propeller to "feather" is an added necessary feature. This causes the blades to turn with their leading



edge into the wind, when the engine is stopped. It cuts down on drag by turning the blade face parallel to the relative wind; and, even more important, it keeps the "dead" engine from rotating. In multi-engine aircraft it is sometimes necessary to stop an engine in flight. If the propeller could not "feather," this engine would windmill, with the result that it would create considerable drag, and might destroy the engine by grinding-up a malfunctioning engine.

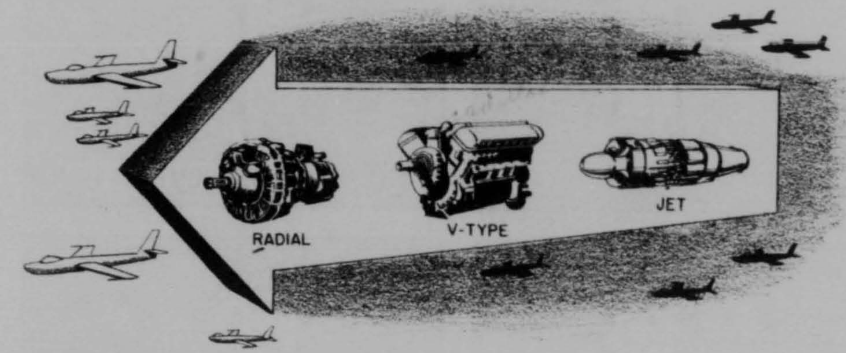
Modern propellers go one step beyond feathering. They reverse their blade pitch. Huge bombers and transport aircraft normally require long run-ways for landing. To overcome this, it is now possible for the pilot to reverse the pitch of the propellers, and then, by adding power, convert the propellers into pusher blades to slow down the roll of the aircraft. This has made it possible to stop these large aircraft in short distances.

The reverse pitch blade has become very

useful for another purpose. It can be used in flight to make it possible for an aircraft to descend very rapidly, without increasing its airspeed appreciably, from a high altitude. With large aircraft flying at very high altitudes the time required for normal let-down is considerable. By reversing the propeller the same aircraft can let down in a fraction of this time.

In summary, it might be added that the rapid introduction of jet-propelled aircraft has brought up the question of the future of the aircraft propeller. In certain usage the jet-propelled aircraft out-performs the propeller-driven aircraft. But for subsonic speeds, at altitudes below 50,000 feet, and for economical operation the propeller driven aircraft is still superior to the jet.

CHAPTER 3 - AIRCRAFT POWER PLANTS



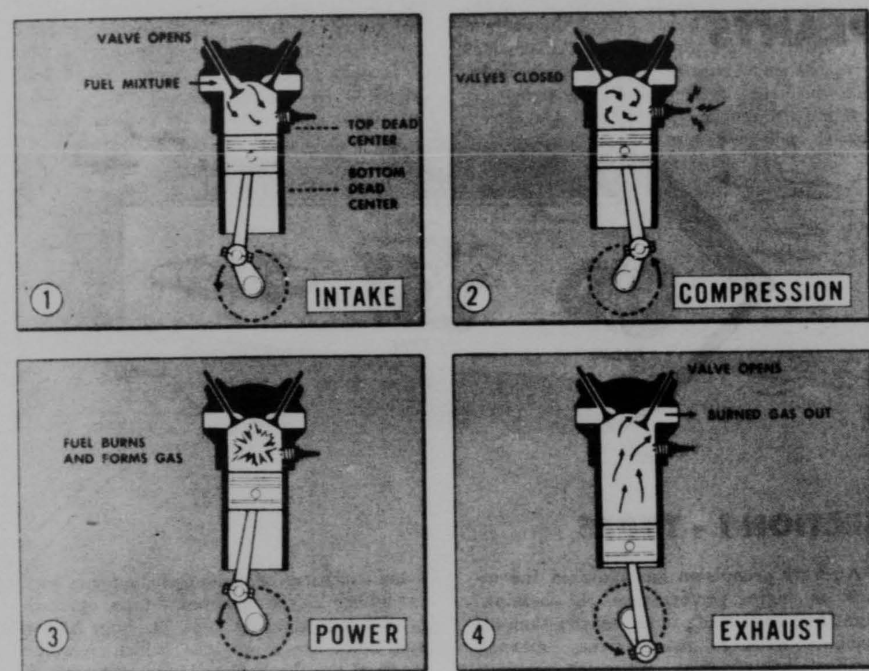
SECTION I - TYPES

Aircraft propulsion has required the utmost in engine performance. No sustained flight had been made in an heavier-than-air machine until a piston-driven, internal-combustion engine was built which combined high power with low weight. A very nearly successful flight had been made with a steam engine before the flight of the Wright brothers, but no wholly successful prototype was made. Since the time of the Wrights' first flight all sorts of engines have been used. One ingenious inventor experimented with a rotary engine. This is not to be confused with the radial engine. All parts of the rotary engine rotated around a fixed crankshaft. The propeller would then be driven by the engine, not the shaft. This engine might have been more successful in the early days of aviation if it had not used direct fuel injection, which at that time had not been perfected.

LIQUID-COOLED ENGINES

The 12-cylinder, liquid-cooled Liberty engine was the outstanding American aircraft engine of World War I and the period following. It was compact and powerful. There were many variations of liquid-cooled engines such as: inline; V-type; inverted V-type; opposed-type; fan-type; and X-type. The huge Allison and Rolls-Royce engines which powered many of the World War II aircraft are outstanding examples of the liquid-cooled engine.

An entirely different family of engines is the air-cooled radial engine. There has been considerable controversy over the advantages of one over the other for aircraft use. The liquid-cooled engine, of course, requires a liquid coolant fluid which adds additional weight. It also requires a radiator, and the necessary cooling system. However, proponents of this type of engine state that its trim, streamline configuration more than offset this additional weight. The sleek "Mustang," "Spitfire," and "Mosquito" of World War II fame bear out this statement. However, there are claims that in combat the liquid-cooled engine is perhaps more vulnerable than the air-cooled. If the coolant system of the liquid-cooled plane is damaged, the engine will fail. In other cases, it has been indicated that the life of the liquid-cooled engine is not as great as that of the radial; this in turn is countered



The piston makes four strokes during the five events which occur in a cylinder in one complete cycle of operation. Two of the strokes are inward, and two are outward.

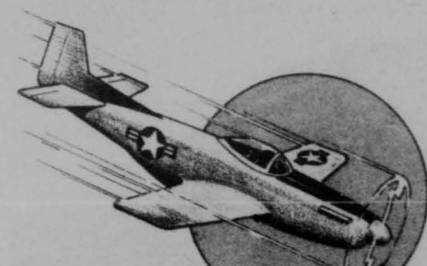
INTAKE STROKE — This stroke takes place as the piston moves out of the cylinder toward the crankshaft. During this stroke the volume within the cylinder is increasing; at the same time, the lowered pressure within the cylinder allows the fuel air mixture to be forced into the cylinder through the intake valve port, which is open.

COMPRESSION STROKE — As the piston reverses its direction and moves into the cylinder, the intake and exhaust valves are closed. The piston decreases the volume of the cylinder chamber and compresses the fuel mixture into a small space. Just before the end of this stroke, a spark from a spark plug ignites the fuel. Notice that two of the events occur during this stroke.

POWER STROKE — The fuel is now burning and as the piston again changes its direction of motion the burning fuel tends to form a large volume of gas. The pressure thus exerted moves the piston. This is the power stroke.

EXHAUST STROKE — When the piston has almost reached the bottom of the third stroke, the exhaust valve opens. Then, as the piston makes the fourth and last stroke of the cycle, it pushes the burned gases out of the cylinder. The cycle now is ready to begin again.

Figure 3-1 Four Stroke Cycle of Reciprocating Internal Combustion Engine



F-51
INLINE ENGINE

with the claim that the liquid-cooled engine runs smoother.

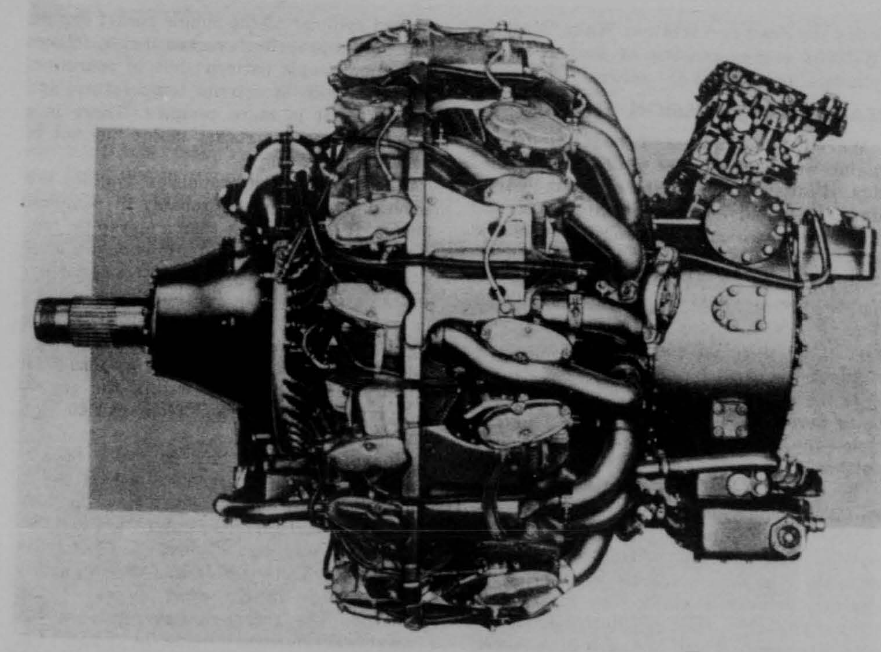
It is not necessary to take sides in this issue. Both types are outstanding propulsion units.

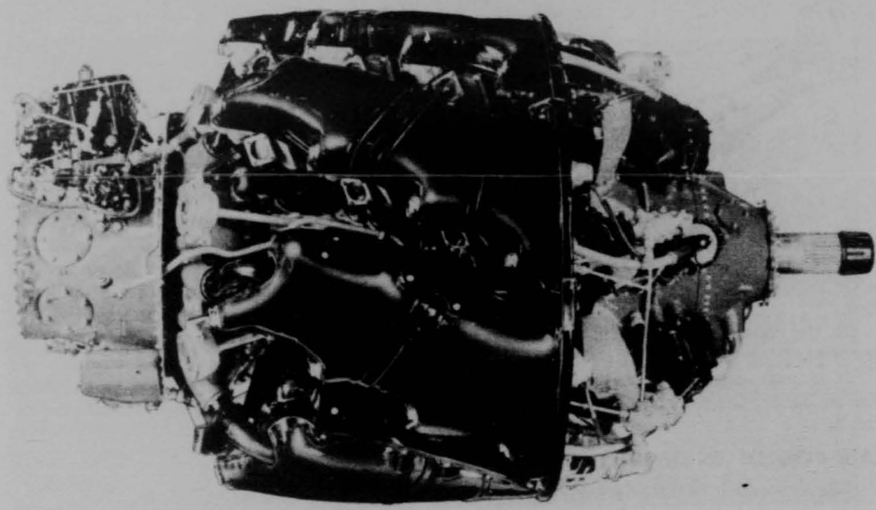
AIR-COOLED ENGINES

The air-cooled, radial engine is a product of the aviation industry. With a few exceptions (early World War II U.S. tanks) it has been used exclusively in aircraft.

The first radial engines consisted of a row of cylinders arranged around the crankshaft like the petals on a flower. As the size of the engine increased the number of cylinders increased, and the overall diameter of the engine increased until it seemed that the radial engine would reach its limit of efficiency because of its great diameter. The victories of the radical engine-powered Gee-Bee aircraft in the Cleveland Air Races, and its world speed-record flights, during the early 1930's helped the cause of the radial engine appreciably, in spite of its diameter. The perfection of the NAC ring cowling and resultant decrease in drag further aided the development of this engine. But the radial-engine designers themselves boosted their own cause best when they developed the twin-row radial.

In effect, two radial engines were harnessed in tandem to a main crankshaft.





PRATT-WHITNEY WASP "MAJOR" (4360) FOUR ROW RADIAL ENGINE.

Today the Pratt and Whitney Wasp "Major" (R-4360) engine consists of four rows of cylinders, one behind the other.

REACTION-PROPULSION ENGINES

While the development of the piston-driven engine was keeping pace with airframe design, it satisfied the demand of the industry. However, the advances in airframe construction and size which came along in the 1930's out-stripped the development in power-plants. Such airframes as that of the B-15 and B-19 indicated clearly that the engines current at that time were not powerful enough, and that there were no adequate power-plants available for such large aircraft.

At the same time a new type of engine was being developed. It incorporated an old principle—the idea of the use of reaction propulsion.

In theory there are countless types of reaction-propulsion engines. Reaction propulsion is used commonly to include jet propulsion and rocket propulsion. Strictly defined, it would include all other types of engines, because basically they incorporate the use of the power of reaction to drive pistons. The simplest motor of all is the powder-packed cylinder of the simple rocket engine. The liquid-propellent rocket motor follows the same simple pattern; but in operation, mainly because of extreme temperatures and pressures, it is more complex. There is a gaseous-propellent rocket motor but not in general use.

The types of jet-propulsion engines are several. The ramjet is probably the simplest design. It is little more than a stovepipe, convergent at each end. The pulsejet engine adds shutters to the ramjet for lower-speed operation. Neither ramjet nor pulsejet can operate from rest without added thrust. The most useful design of all present jet-propulsion engines is the turbojet. By means of the compressor and turbine within the engine this type is self-sufficient from rest to high speed.

Summarizing the various types of aircraft engines there are many others which might be mentioned. The turboprop uses the compressor-turbine combination to drive a propeller, and is an efficient engine of great importance. The turbo-ramjet uses an added ramjet stage in the after-burner of the turbojet. The rocket-ramjet combines the rocket and ramjet to provide the ramjet with

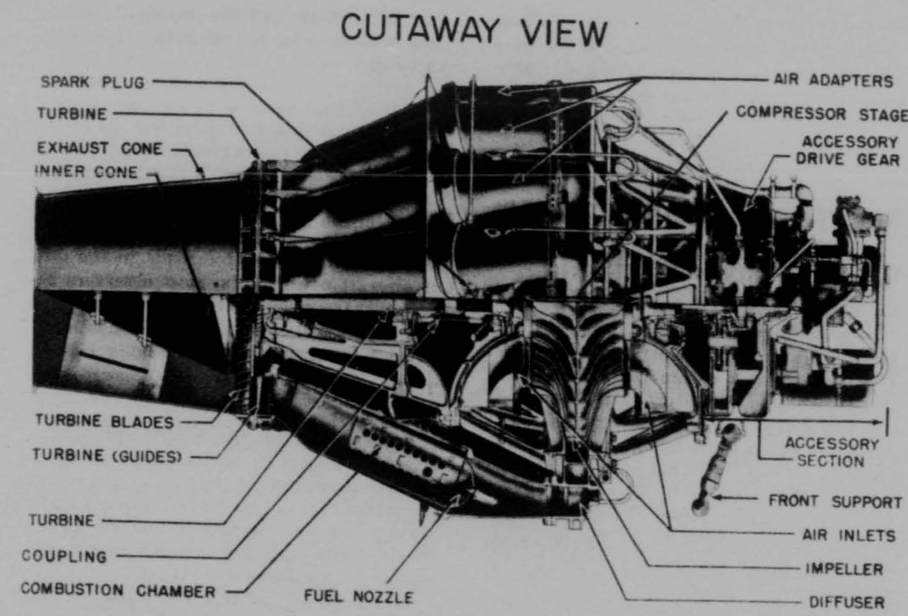


Figure 3-2 Cutaway View of Jet Engine

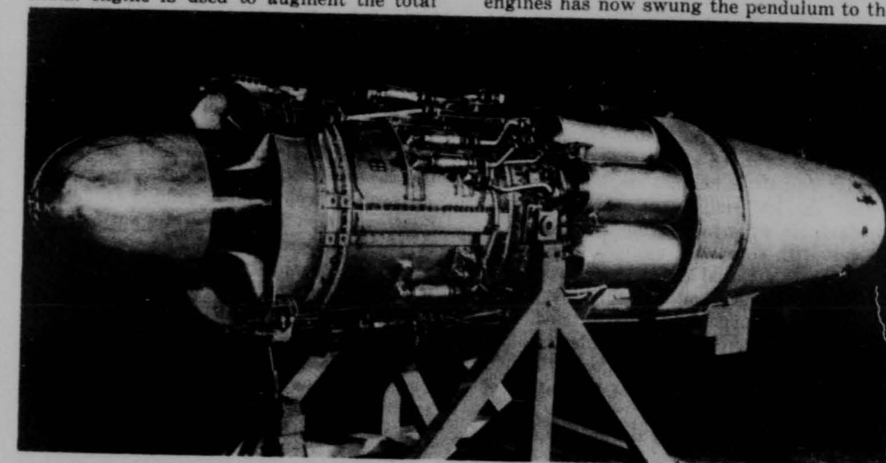
internal thrust from rest. Radial engines have been used as compressors coupled with a turbine. In other cases the exhaust of the radial engine is used to augment the total thrust of the power unit. Whatever the combination, or in cases where the reaction engine is used by itself, this new family of engines has now swung the pendulum to the



opposite side. The power plant has now outdistanced the airframe. Today the engine manufacturer is constantly trying to find a suitable airframe for his powerful engine. Engines of 5,000 to 7,000 pounds thrust are now in service; for full utilization they await super airframes.

SECTION II - OPERATION

1. PISTON-DRIVEN INTERNAL COMBUSTION

Both the liquid-cooled and air-cooled engines operate on the same basic principle. The piston moves within the cylinder in a four-stroke cycle. (See Figure 3-1) The successive power strokes of the many cylinders are applied in series to the crankshaft. It is this series of strokes which keeps the crankshaft moving. The crankshaft, in turn, delivers this force to the propeller. Not all the power of the engine is delivered to the propeller. The basic engine must furnish power for the operation of the accessories such as: generator, hydraulic pump, fuel pump, oil pump, and supercharger. Most of the useful power is applied to the propeller. The propeller then utilizes this power to accelerate a large mass of air to the rear. The reaction to this force moves the aircraft forward.

This operation is much like that used by a swimmer in water. A man floating on the water remains motionless. Then, when he begins to move his arms and legs, he pushes on the water; and, because the water pushes on him (offers resistance to his thrust) he moves forward.

In some instances the piston-driven engine is not used to drive a propeller. One of the first jet-propulsion engines employed a piston engine for its compressor stage. Recently considerable experimentation has been underway with compound engines. Such combinations as a radial engine and one or two gas-turbine stages, plus a turbo-jet stage with an after-burner—have been tried. This compound engine drives a propeller in addition to its jet thrust. The purpose of such a combination is for the fullest utilization of fuel.

In spite of the fact that the jet-propulsion engine has made great inroads in the field of aircraft power units, most observers believe that the piston-driven, internal-combustion engine will be used for various types of aircraft for many years to come.

2. REACTION PROPULSION

Definition

Perhaps because the reaction-propulsion type of engine is so new, a universal definition for it and for jet propulsion and rocket propulsion has not evolved. There are many texts which use reaction propulsion as the over-all term including jet and rocket propulsion as its two sub-divisions.

There also are other texts, equally as authoritative, which refer to jet propulsion as the over-all term including rocket propulsion. Fundamentally Newton's third law applies: "For every acting force, there is an equal and opposite reacting force." Here the term "acting force" means the force one body exerts on a second body, while "reacting force" means the force the second body exerts on the first. Therefore, it should follow that all engines operate on the reaction principle; and further that direct-propulsion engines are primarily reaction propulsion, and then subdivided into jet propulsion and rocket propulsion. For the purposes of this course the above definition will apply.

Reaction propulsion is defined as, "a propulsion system in which a forward motion or thrust is produced by the expulsion of propellent gases through nozzles or venturi, generally longitudinally opposed to the intended line of travel." This definition, in effect, draws a line between the reciprocating engine and the piston-driven, internal-combustion engine. Actually the piston-driven engine and the reaction engine are both internal combustion engines.

Jet propulsion is defined as "reaction propulsion in which the propulsion unit obtains oxygen (and mass) from the air as distinguished from rocket propulsion in which the unit carries its own mass and comburent material. In connection with aircraft propulsion, the term refers to a jet unit which discharges hot gas through a tail pipe and a nozzle, affording a thrust which propels the aircraft." Before proceeding further on definitions we should study the principles underlying the theory of reaction propulsion for aircraft.

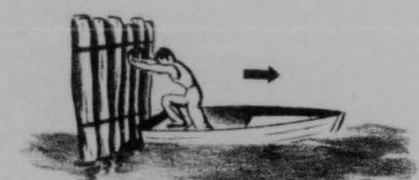
Principle of Reaction Propulsion

Although the idea of reaction propulsion is very old, many people do not realize how it is possible for an aircraft to fly without some visible means of propulsion. It is common belief that the supersonic stream of air which is emitted by the jet engine (for purposes of simplification the term "jet engine" will be used as an example of all types of reaction engines) pushes against the outside air and that this somehow pushes the aircraft along. Such ideas are wholly erroneous. If this idea were true, a jet plane would take off quicker if it were backed up against a wall. If this is not true then, what is the explanation?

The jet engine is moved forward by the same physical factors which cause any other engine to move forward—by reaction to the action of the engine. The following example will help to explain how the reaction principle operates. If a person were in a small rowboat in the middle of a calm lake, how could he make this boat move without using oars? All that would be needed would be a water bucket.

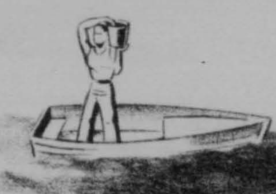
He could dip the bucket in the water and then heave the bucket-full of water over the stern of the boat. The boat would move forward. Why?

If the boat were backed up against a wall,



this would be easy to see. He could push on the wall,—that would be the acting force; in return the wall, by resisting the push, returns the push on him,—that is the reaction force. This "push" on him is transmitted by his feet to the boat, and the boat moves forward. It is easy enough to realize that the boat would move forward if he pushes on a wall. Now to take up the next step.

In the case of the bucket of water, at rest

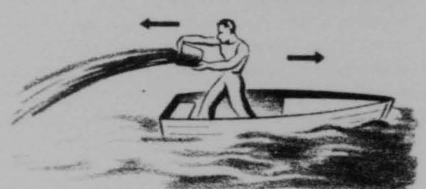


in his hands it has inertia. By application of Newton's first law a body at rest tends to remain at rest until it is overcome by an unbalanced force. Therefore the bucket of water will remain at rest, in his hands, until he applies force to it. Now this brings up the idea of acceleration. If he pushes gently against this bucket of water, he will just cause it to be poured out easily; and only a small reaction will occur. But if he takes this same bucket of water and hurls it with all his might, he will be putting in a large acting force (he will be accelerating this mass of water rapidly), and the force of reaction will be equal to it. His push against the

THIS PAGE IS DECLASSIFIED IAW EO 13526

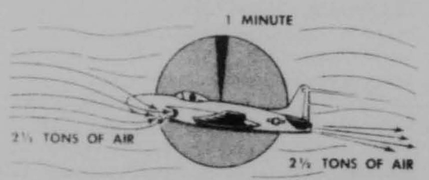
bucket of water will work in the opposite direction, just as though he were pushing against the wall with the same amount of force; and the boat will move.

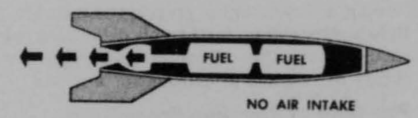
A jet engine does not just throw one bucket of water (mass) overboard. It throws a steady stream of air (mass). To make the boat operate like a jet aircraft the person now becomes the engine; he scoops up water (air—"mass") and hurls it (acceleration of mass) overboard as fast and as forcefully as he can.

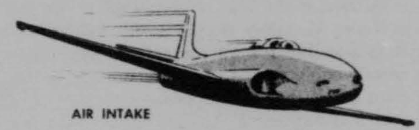


As a result the boat will move along, just as a jet aircraft moves along. It moves because he (the engine) is pushing against (accelerating) a mass of water; and not because the water he is hurling is pushing on the air or on anything else. This is the important part of the whole reaction-propulsion idea.

Now to relate this directly to the jet engine and using the J-33 type as an example. In normal operation this engine scoops up in its air intake scoops, and hurls overboard through its tail-cone, a mass of 2½ tons of air per minute. 2½ tons of air is a tremendous volume; yet this mass is accelerated by this engine every minute as a steady stream. This mass, plus the mass of the fuel consumed in a minute, is the "wall" or "bucket of water" against which the jet engine pushes. The jet engine pushes this air out, and in return it is pushed forward with an equal force.







The difference between the jet engine and the rocket motor is slight. The principle is the same. The jet engine needs air for the mass which it pushes on (accelerates), and to provide the oxygen which it needs to support combustion. The rocket motor carries its own comburent agent (oxygen as an element of gunpowder, or liquid oxygen as a part of its propellant) whether it is a solid-fuel rocket or a liquid-fuel rocket. This difference points out the advantages of each type. The jet engine, because it does not have to rely on mass and oxygen carried with the aircraft, operates more efficiently in the atmosphere; but of course is limited to operation in the atmosphere.

Meanwhile, the rocket motor, because it is self-sufficient can operate most efficiently beyond the atmosphere in a vacuum. When one realizes that the reaction-propulsion principle functions by the push applied to the mass inside the engine, it is easy to understand that a rocket works best in a vacuum. As an example: The air has weight; it is a fluid; it is relatively dense. Therefore, when a jet engine is at sea level, it has to push the mass of air out into that "dense" air. As a result, it has to work harder at sea level than it does at high altitude. In a vacuum there would be no pressure at all outside the tailpipe; so the engine could hurl its mass of

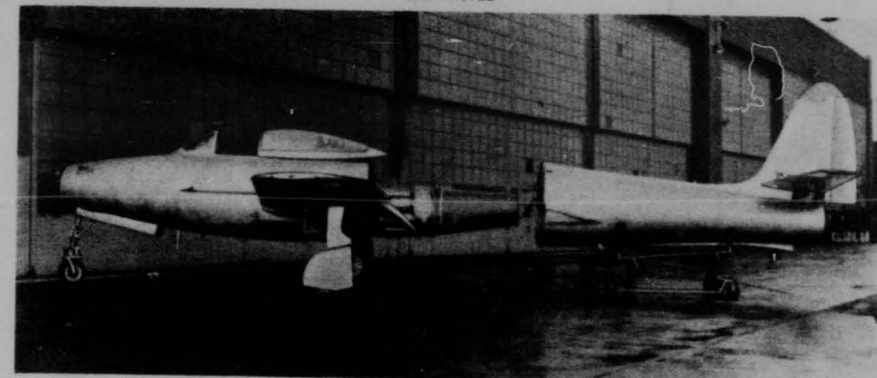


Figure 3-3 Bisected View of F-84 Showing Engine Position

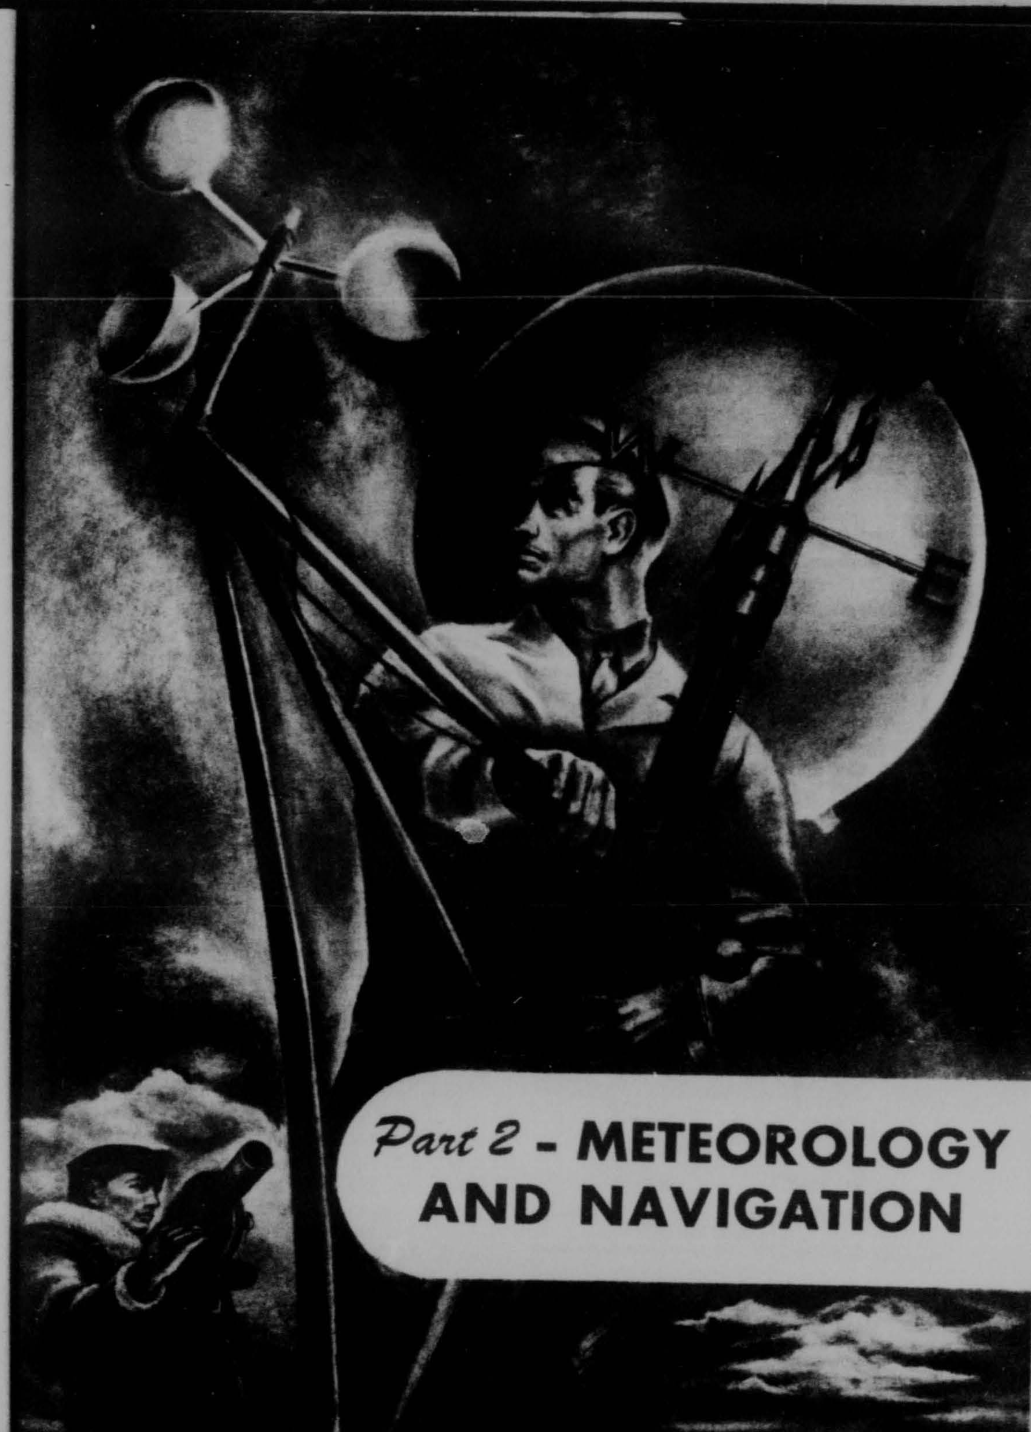
air out easily. Of course the air at high altitude, though it is thin, is not vacuum; but it approaches a vacuum.

When one throws a baseball, one has no difficulty hurling it through the air; but, if one tries to throw a baseball underwater, one finds that the harder one tries to throw the less it seems to move. One would realize that it is most difficult to accelerate a mass in a dense fluid. This is the problem which a jet engine, or rocket motor, encounters at sea level; but the higher the engine goes (other things being equal) the easier it is for the engine to operate.

In thin air, at high altitude, the engine must move faster (travel farther) to scoop up the same volume of air which it did at sea level. And because this thin air creates less drag over the airframe at high altitude, the engine does move the aircraft very fast. The faster the jet engine goes, the more efficient is its operation. Actually the same J-33 jet engine, which develops 4000 pounds of thrust at sea level, develops but 1000 pounds at 35,000 feet; but 1000 pounds at 35,000 feet drives the aircraft faster than 4000 pounds does at sea level.

We have now reached the conclusion in this discussion of "aerodynamics and propulsion." We have only scratched the surface of this very complex subject. In this present period, the power plant has outstripped the airframe; but steps are being taken to close the gap. And this is where the interesting part of the story lies. New airframes with "delta" wings, with swept back wings on which the angle of sweep may be changed in flight, supersonic biplanes, and the use of propellers for supersonic aircraft; supersonic helicopters; and many other designs are being tested.

Furthermore, the whole realm of high-altitude flight creates a new flying world. Temperatures as low as —110 degrees F are encountered, radar refuses to function as predicted, equipment is inoperative because of the cold, and other allied problems create new fields to be explored. This part of the book can not be concluded, it merely comes to an end at a certain page with a limitless story still spread and before it.



Part 2 - METEOROLOGY AND NAVIGATION

CHAPTER 1 - WEATHER

SECTION I - RELATIONSHIP OF WEATHER TO THE AIR FORCE

1. INTRODUCTION

In reading a list of flying regulations prepared in 1918 for one of the first bases established in Alabama, it was noted that the regulations were a bit crude and very brief. One point, however, stood out above the rest—the element of weather. One regulation read, in part: "On cross country flying, remain below the clouds, it may be difficult to find your way through them again." Although it is not necessary to be quite so naive in modern regulations, weather still remains the governing factor in flight planning, whether it is for a cross-country training flight by single airplane or for a major tactical operation involving thousands of bombers and fighters.

In 1934, the importance of meteorology and weather flying was brought home dramatically and tragically to the Army Air Corps. At the order of the President, the Air Corps agreed to fly the mail. But Army pilots were not trained competently to cope with flying through difficult weather, and crashes were all too frequent. The loss of men and airplanes, however, had one salutary effect. Realizing its shortcomings, the Air Corps revamped its training program, and, along with other changes, meteorology and weather flying received major emphasis.

Modern science has made possible flight through almost any type of weather, but restricted visibility and other weather factors still remain the greatest hazards to flying. In addition to improving aircraft, flight instruments, and communication facilities, the progress made in obtaining and disseminating meteorological information has been of utmost importance in making weather flying relatively safe.

Perhaps the greatest evidence of the importance of meteorology to military flying was demonstrated in World War II. The near-disastrous results of the "Battle of the

Figure 1-1 Preparing a Radiosonde System for Its Flight Into the Upper Atmosphere

THIS PAGE IS DECLASSIFIED IAW EO 13526

Bulge" were due to a large extent to weather which prevented effective use of aircraft by the allies until the last stages of the battle. In an earlier instance the German fleet was able to sneak two battleships through the English Channel under the cover of fog. These are but two examples of the part that weather played in the moves and countermoves of combat.

2. WEATHER INFLUENCES ON PLANNING AND OPERATIONS

Effect of Weather on Base Location and Structure

Consider the weather factor as it affects the choice of an airfield site, the buildings that are going to be placed upon it, and the types of runways that may have to be used.

Location. It is conceded that there are many other factors besides weather conditions that should be considered in the location of an airbase. Unfortunately, however, many airbases have been located without regard to the possible influence of weather. Some of our own airfields, located on the leeward side of smoke-producing cities offer one outstanding example. Their location on the side of the city from which the prevailing winds blow would have reduced substantially the restricting visibilities from which they now suffer. Some of the airfields used by our tactical air forces in Europe were flooded when excessive rains caused nearby streams to overflow their banks.

There is a noticeable difference in the flying weather along the Pacific Coast of British Columbia and Alaska and that prevailing over the interior behind the mountains. The coastal weather is usually wet and cloudy. Weather at inland bases is much cooler in the winter, but also much drier, and on the whole, much more suited for bases from which to conduct aerial operations.

Structure. The weather factor must be considered in determining the types of buildings that are to be erected on an airfield. Some of the hurricanes that have occurred on the Gulf Coast have shown that the builders failed to consider the wind velocities to which some of the hangars would be subjected. Strong winds are not limited to the hurricane belt of the Gulf Coast. In Greenland, about the only places from a topographic standpoint that airbases can be located, on the east and west coasts particularly, are in the fiords. Air sliding down off the Greenland icecap to the sea has been known to blow through the fiords at velocities of more than 120 miles per hour. Winter winds up to 80 miles per hour have been recorded in the Canadian Arctic. Obviously, buildings in the far North must be well insulated to keep out winter temperatures of 50 to 60 degrees below zero. This insulation is necessary from a fuel economy standpoint as well as for personal comfort.

A weather factor entering into the construction of runways is the direction and velocity of the prevailing winds. Soil and temperature considerations also are important. Some clays and volcanic ash swell or "heave" when they get wet. This "heaving" action is much like that which occurs when one cooks rice with water. The whole mass ends up with a volume apparently larger than both volumes combined. A runway laid in "heaving" soil will not be a runway very long. The temperature range of the area in which the runway is to be laid must be taken into account. In the Arctic, summer maximum temperatures often go well up into the 90's, and sometimes reach as high as 100°. In the winter, temperatures may slide down to as low as 50 to 60 below, and sometimes even lower for short periods. This wide annual range in temperature imposes severe demands on the expansion capabilities of a runway, and is one of the problems that must be considered in planning bases for Arctic operations. Much of the ground in the Arctic is tundra. This freezes in the winter but thaws in the summer for the first few feet and remains frozen deeper down. In summer, the ground cannot drain effectively due to the frozen ground below it, so a soft mass results. No effective way of overcoming this difficulty yet has been found. With our present heavy aircraft this presents a difficult problem to overcome.

These factors indicate that the weather is an important factor to be considered in construction of air fields. The best that can be done to overcome the weather factor or properly account for it in planning of air bases is to make a climatic study of the area and

assess the weather factor from that.

Influence of Weather on Offensive Missions

In planning an aerial offensive, the weather factor assumes the highest importance. What type of aerial offense will be conducted? Will it embrace nighttime, or daytime operations, or both? How many of the missions may be required to utilize instrument bombing techniques and how many may be expected to be visual?

Type of Mission. With respect to night operations versus daytime operations, many of the industrial areas of the world lie in areas under the influence of maritime air; that is, air that has had a long trajectory over water. In the absence of frontal activity which produces general cloudiness, this maritime air is likely to react to daytime heating by producing cloudy conditions. These conditions often are accompanied by thunderstorms or showers. As evening approaches, the clouds usually decrease and skies are clear the greater portion of the night. A complaint frequently heard in the European theater was: "Why isn't the weather as good in the daytime when we are running our missions as it is at night?" The same thing occurs in the Gulf Coast area.

Thunderstorms, rain, and snow showers resulting from daytime heating must be taken into account in planning instrument bombing techniques. A thunderstorm or a shower will reflect electromagnetic impulses very well. There is no telling how many thunderstorms, snows, and rain showers were bombed in the last war. It definitely happened in more than one instance. Due to the lower freezing level in the northern latitudes, maritime air will produce showers from clouds with less build-up than is normal in the Gulf Coast area. This is particularly true in the wintertime when snow showers fall from clouds with insignificant build-up. The farther north, the more limitations are forced on flying operations. Advantage must be taken of the best seasons. At all times must every aspect of probable weather conditions be considered in planning day or night flying operations.

Size of Force. What will be the magnitude of the operations? What size mission shall be planned? If the A-bomb is used, it must be delivered to the target if the mission is to be effective; it is of no value in the bomb bay of an airplane. Will three planes be sent out to a single target on the theory that two of them may abort because of weather? Or, will it be necessary to send five or ten? Will an average of one plane out of three or five get through the weather. Suppose that the conventional type of bomb is to be employed. This involves the operation of large forces of bombers. The larger the force, the more weather must be considered in planning, due to the loss of maneuverability which accompanies the increase in numbers. To what extent will the weather over our bases limit the size of the force that can be sent? To what extent will the weather along the route influence the size of the force? All these questions must be answered in some way before a meaningful plan can be evolved. The weather factor may not be the only factor or even the controlling one, but it is a factor that must be taken into account.

Effect of Weather on Defensive Operation

The weather factor is not quite as important in air defense plans as it is in air offense. However, consideration of weather as it affects the enemy's ability to operate may provide a clue to the extent of his operations during certain periods of the year.

If the whereabouts of enemy bases and the types of equipment he is using are known, general assumptions regarding the type of weather conditions that would limit operations out of those bases may be made. A climatic study would show the frequency of those limiting weather conditions by month or season.

Weather would enter into the location of interceptor bases in the same manner previously mentioned in connection with planning bases from which to conduct offensive operations. Interceptor operations in the air defense of the Los Angeles Basin area are more difficult than in the interior. Along the coast, aircraft are likely to encounter fog, low stratus clouds, haze, and frontal weather. Bases should be located in the area of good weather with the mountains between the

THIS PAGE IS DECLASSIFIED IAW EO 13526

bases and the sea.

It is evident, therefore, that weather should be considered in air defense plans mainly from the standpoint of estimating enemy capabilities and in locating interceptor bases. Again, the climatic study is the only means available for assessing the influence of weather in plans for air defense.

SECTION II - CLOUDS AND SKY CONDITIONS

1. CLOUDS AND WEATHER

One of the things most commonly associated with weather is the presence or absence of clouds. Bad weather is commonly thought of in terms of large, black, clouds and precipitation. A nice day is thought of as one during which there is a clear blue sky with patches of white fluffy clouds floating about. Clouds are like store signs. They tell what may be expected inside. Knowing how to read these signs is invaluable knowledge to the pilot. Clouds should be considered not only in the light of what should be avoided, but also in the light of how they can be used for concealment.

2. SKY CONDITIONS AND CEILING

In referring to cloud cover, meteorologists refer to the "ceiling."

Definitions

"Sky condition" refers to the coverage of the sky by clouds. "Ceiling" may be thought of simply as the height of the base of the clouds, in feet, above the ground, providing the clouds cover more than five-tenths of the sky. A ceiling is said to be unlimited when the cloud cover is five-tenths or less, or the base of the clouds is above 10,000 feet.

Amount of Coverage

When five-tenths or less of the sky is obscured by clouds but more than one-tenth is covered, the sky condition is referred to as **scattered clouds.** If more than five-tenths of the sky is covered but a portion is visible, the sky condition is then referred to as **broken clouds.** Broken clouds constitute a ceiling if more than nine-tenths of the sky is covered. If the sky is completely hidden by clouds, the condition is known as an **overcast.** A pilot flying through or over an overcast, or a broken condition, is said to be flying under instrument conditions because he cannot maintain his bearing or his course by visual reference to the ground.

Ceiling Classifications

In general, ceilings are classified according to the manner in which they are observed or measured, and are reported accordingly. They are correctly reported to the nearest 100 feet.

Measured Ceilings. Measured ceilings are ceilings that are measured accurately by some type of mechanical device or an accurate reference. Some of the methods of measurement are as follows:

Ceilometer. The ceilometer is the most modern instrument developed for measuring ceilings. A modulated beam of light is projected to the base of clouds. Some distance away on a measured base line is an "eye" equipped with a photoelectric cell which scans the beam of light and locates its intersection with the base of clouds. The angle between the horizon and the line between the "eye" and the intersection of light beam and base of clouds is recorded automatically in the weather station. The height of clouds is equal to the length of the baseline multipled by the tangent of the above angle.

Ceiling Light. During the hours of darkness, the height of the base of the clouds may be determined by the use of a light known as the "ceiling light." By observing the point at which the light strikes the overcast through a clinometer (a device very similar to the common transit) some distance away on a measured base line, and applying triangulation, the height of the base of the clouds may be determined accurately.

Radiosonde Balloon. A small radio is attached to a hydrogen-filled balloon and allowed to ascend into the overcast. This radio transmits values of pressure, temperature, and moisture content of the air at regular intervals to a ground recorder. The point at which the radio strikes cloud cover can be determined by analyzing the changes in moisture content.

Balloon Ceilings. The ceiling height may be calculated from the rate of ascent and time of ascent of a hydrogen-filled balloon into the overcast. This method is less accurate than some of the other methods.

Indefinite Ceiling. In many instances the base of the clouds is very indefinite. The bottom may be uneven or very thin and it is difficult to determine just when a balloon enters into the overcast or just where the ceiling light strikes the clouds. This type of ceiling is known as an "indefinite ceiling" and is reported as such.

Aircraft Ceiling. These are determined by requesting a pilot flying over a weather station to report the height of the base of the clouds as read on the aircraft altimeter. The pilot may radio this information of his own volition.

Estimated Ceilings. As the name implies, an estimated ceiling is one that is estimated without the use of mechanical aids by a weather observer on the ground. It is one of the most common methods of determining ceilings. The inaccuracy of this method is quite obvious. However, an experienced observer usually will be correct to within a few hundred feet.

Precipitation Ceiling. A precipitation ceiling is not necessarily the height of the base of the clouds, but is the altitude at which a pilot would not be able to have visual reference to the ground due to the amount of precipitation. This type of ceiling may be determined by any of the above methods, especially pilot reports, the use of balloons, or estimations.

3. CLOUDS

Clouds are the most important single weather element visible to the aviator, and their proper analysis should be the constant goal of all personnel interested in the operation of aircraft.

When a volume of air is cooled, it has a greater mass per unit volume of water vapor. After the saturation point is reached, condensation may occur in either a liquid or solid form, depending upon whether the temperature is above or below the freezing point. Condensation does not occur throughout the entire mass of the humid air, but around small condensation nuclei, chiefly smoke or dust atmosphere. A cloud is composed of a great number of small water droplets, ice crystals, or both, which are separated from each other. The diameter of the water droplets is very small, ranging from 1 to 70 microns, with the most frequent diameter being 12 microns. There are about 50 to 500 of these particles in a cubic centimeter of cloudy air. The rate of fall of these droplets is so small, a few millimeters per second, that the slightest ascending air current is sufficient to hold them aloft. Rain drops, on the

THIS PAGE IS DECLASSIFIED IAW EO 13526

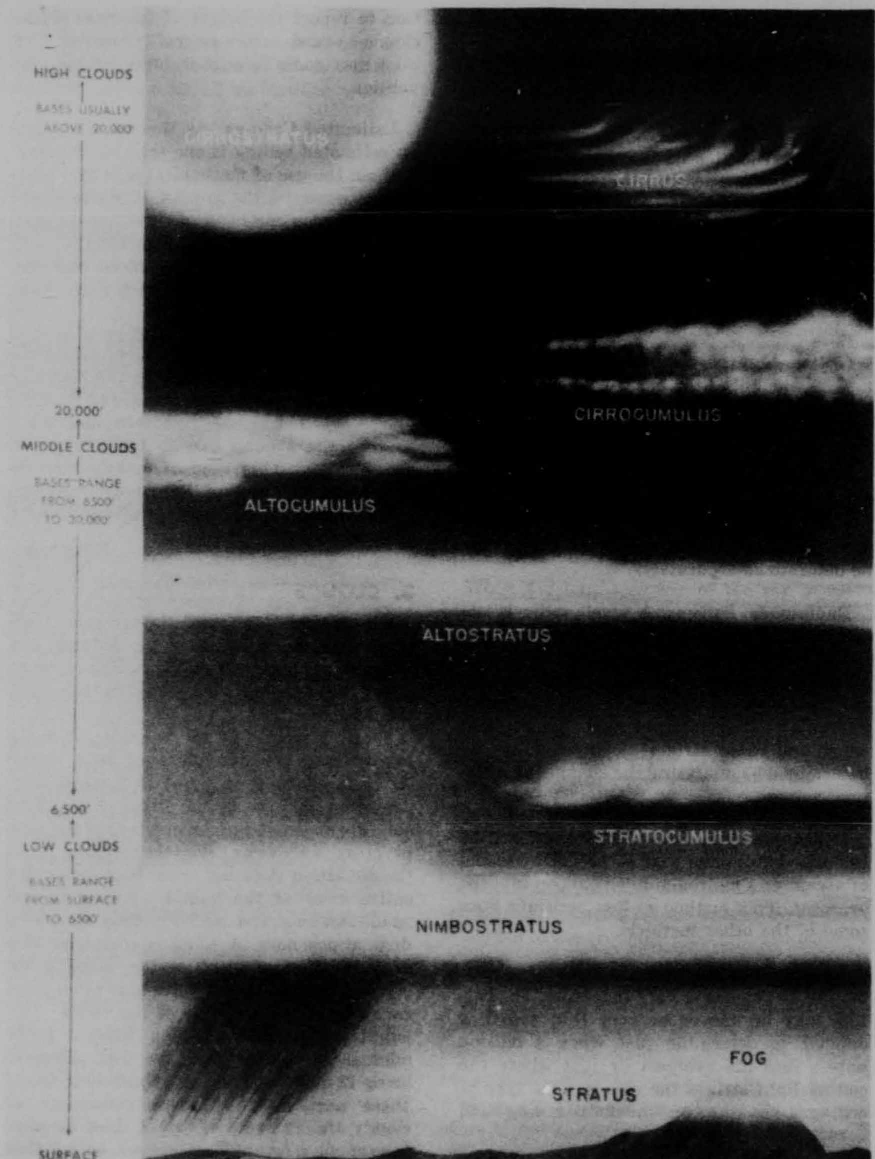


Figure 1-2 International Classification of Clouds

WORLD POLITICAL GEOGRAPHY AND AIR POWER

1. Political geography is defined as the study of the areas and resources of the various states organized as political units, together with the people who live in these areas. Applied Air Power is in a large sense applied political geography since the proper application of air power is based on careful consideration of the facts and principles of political geography with regard to enemy states. The most effective application of air power must take into account such geographic factors as the climate, topography, drainage, natural resources, urban pattern, transportation and communications, industrial facilities, and population distribution of the country under attack, and perhaps of allied and neutral nations as well.

2. The objective of warfare is the destruction of the enemy's capacity and will to fight. Modern mechanized, technical warfare is based on a complex industrial organization and the enemy's war potential can be neutralized most effectively by striking at the heart of the system producing war materials. Air power provides practically the only immediate means of bypassing battle lines and defense lines and reaching these targets, many of which are located far from national boundaries.

3. Proper consideration of geographic factors in the assigning of target priorities can result in neutralizing much of the industrial potential of the enemy. The effect of the destruction of finished products is felt more quickly at the battle-front, but the destruction of raw materials and production facilities is more lasting, even permanent, in effect. A tank arsenal is an obvious target, but much more damage to the enemy would result from destruction of a plant making steel, sulphuric acid, ball-bearings or nitrates.

4. A knowledge of geography will reveal not only an enemy's deficiencies in strategic materials such as tungsten, foodstuffs, ball-bearings or petroleum, but his source of supply and the route of delivery. Attacks can then be directed against transportation lines and port facilities for handling such materials.

5. Damage to transportation systems prevents, at least temporarily, the delivery of supplies to the fronts and raw materials to industry and the movement of troops and reinforcements. Best results can be achieved by attacks on bottle-necks or especially vulnerable points such as cuts, fills, bridges, passes, tunnels and other stretches of single track or service facilities such as round-houses and repair shops. Deductions as to the location and vulnerability of such targets can be made from the topography and drainage pattern of an area and its industrial organization. For example, damage to the New York State Barge Canal would not be of primary significance, while damage to the Soo Canal would seriously cripple the American steel industry.

THIS PAGE IS DECLASSIFIED IAW EO 13526

6. With the increasing tendency to disperse defense plants and keep their location secret, geographical information is more important, since geography imposes many limitations on location of factories and transportation lines. A knowledge of climate may help determine the best time of year, or even the best time of day, for operations and will aid in the selection of special equipment necessary for successful missions.

7. Increasing recognition of the importance of psychological warfare gives added significance to the distribution of ethnic, religious, racial, cultural and political minorities. Concessions to the problems, attitudes and aspirations of such people may contribute to the effectiveness of air power in destroying the enemy's will to fight.

8. In the use of air power in tactical situations a knowledge of the topography and transportation system is essential in inhibiting the enemy's use of a facility, harrassing his operations or interdicting an area.

9. Political geography provides information in the light of which we can most efficiently seek intelligence for the application of air power and evaluate the significance of information when it is obtained. It provides a frame of reference for drawing sound conclusions regarding strategic and tactical situations. Furthermore, it implements our traditional American policy of training an informed fighting man, one capable of drawing logical conclusions concerning our security problem.

other hand, which are composed of an accumulation of small droplets, are comparatively large and fall with appreciable velocities.

In general, clouds are divided into two main classes according to their form or method of development. Those that form in layers and have horizontal development are known as stratiform clouds. Those that have vertical development are known as cumuliform clouds. So that clouds may be discussed internationally, there is an international cloud classification which is based primarily on height. In brief, this classification is as follows:

High Clouds	20,000—40,000 feet
Middle Clouds	6,500—20,000 feet
Low Clouds	Surface— 6,500 feet
Clouds with vertical development	All Altitudes

Stratiform Clouds

STABLE AIR

(See Figure 1-2.) Stratiform clouds are flat, occur in layers, and usually form in stable air. Stratiform clouds generally cover large areas, and the air within and around them is smooth. They are generally associated with warm air masses or warm fronts, which will be discussed in the following chapter. Stratiform clouds are produced by the cooling of certain strata of the air. Such cooling takes place in one of two ways: radiational cooling by a land surface; and advective cooling, which occurs when the air is lifted over a gentle slope. In either case, the air near the surface, or some strata of the air becomes cooler and therefore heavier than the air aloft. As a result there is little or no vertical circulation. If this cooling is sufficient to lower the temperature of the air to the point of condensation, stratiform clouds will be produced.

Flying Condition Associated with Stratiform Clouds. In stratiform clouds, because of the absence of vertical currents, water drops need overcome only the buoyant effect of air before falling as precipitation. As a result, stratiform clouds yield small-drop, continuous precipitation. There will be little evidence of turbulence in this type of cloud, and other than restriction to visibility, they present no great hazard to flying. At temperatures from 0°C. to —18°C, icing may occur, however, the icing is usually of a not too dangerous type known as "rime ice." (Ice forms on the wings in the form of small pebble-like droplets similar to sleet. It usually is easily removed, and the icing is relatively slow.) In nimbo-stratus clouds when temperatures are between 0° and 90° clear icing usually occurs.

FLYING CONDITIONS GOOD

Types of Stratiform Clouds. Cirrus. (See Figure 1-2.) Cirrus clouds are fibrous and delicate in appearance. They look like white wisps against the blue of the sky. These white wisps appear in a number of forms. Sometimes they appear streaked across the sky and look like mares' tails; at other times they appear as curls or feathery plumes. Cirrus have little thickness and have little significance other than that they may indicate the approach of a warm front if they appear thin at first and then become more compact as they move over. They are very high clouds and are composed of ice crystals.

Cirro-stratus. (See Figure 1-2.) Cirro-stratus appears like a white veil covering all or most of the sky. It forms in a smooth, thin layer and gives the sky a very milky appearance. Cirro-stratus is identified easily by the halo it produces around the sun or the moon. Like cirrus clouds, cirro-stratus is a very high cloud and is composed entirely of ice crystals. Their presence indicates the approach of a warm front.

Cirro-cumulus. (See Figure 1-2.) Cirro-cumulus clouds appear like fleecy flakes or very small white cotton balls. They are very uncommon, appearing only in the presence of cirrus or cirro-stratus. They are high clouds of ice-crystal composition and, like all cirrus type clouds, are found at the level where condensation trails may be formed.

Alto-stratus. (See Figure 1-2.) Alto-stratus appears like a grey or blue-grey, smooth cloud layer from the ground. It is usually thicker and less transparent than the cirro-stratus, which often lowers and merges with alto-stratus as a warm front approaches. The sun and moon shine through alto-stratus weakly as though through a ground glass. The upper surface is wavy or bumpy in appearance. The alto-stratus is a middle cloud that is composed of water droplets. Due to the fact that it is

Figure 1-3 Clouds in Vertical Development

a middle cloud and covers large areas, it is often used tactically for concealment purposes.

Alto-cumulus. (See Figure 1-2.) Alto-cumulus sometimes looks like cirro-cumulus, but the individual cloud balls or flakes are always large, thicker and more gray. The center of the underside of each cloud is dark due to the cloud's thickness. These ball-like masses often appear like a herd of sheep. The visibility within them is poor and the clouds lack continuity. Turbulence and icing, if any, are light to moderate. During the war, fighters often used them for ambush purposes. They are middle clouds.

Nimbo-stratus. (See Figure 1-2.) Nimbo-stratus clouds are thick, dark, ragged clouds, ominous and formless in appearance. Rain, snow, or other precipitation normally is falling from this type of cloud. Even if the rain temporarily stops, this cloud has a ragged, rainy appearance and is still called nimbo-stratus. The sun or moon is not visible through it. Nimbo-stratus is usually at least 6,000 to 8,000 feet thick and often blends into the alto-stratus above. Bases sometimes reach the surface of the ground.

Stratus. (See Figure 1-2.) Stratus is a flat, shapeless, rather uniform layer of cloud appearing dull gray and looking like fog when viewed from below. Stratus-type clouds are often confused with nimbo-stratus but differ mainly in the amount of precipitation that is falling. Stratus never yields more than a slow

drizzle. It is a low cloud whose base may reach nearly to the surface of the earth.

Strato-cumulus. (See Figure 1-2.) Strato-cumulus usually occurs as an extensive and fairly level layer marked by thick rolls and dark, rounded mass of clouds. Strato-cumulus may or may not have large breaks between the rolls and masses. Viewed from above it has a cumuliform appearance but does not have the same vertical development. The thickness varies from 500 to 4,000 feet and turbulence may be light to moderate. Occasionally, light rain, or snow may fall from strato-cumulus clouds.

Cumuliform Clouds

Cumuliform clouds are clouds with vertical development. They occur in unstable air, and the air within them and around them is turbulent. Cumuliform clouds may be a result of the heating of the earth's surface within an air mass, the sharp lifting of air by a cold front, or some orographical effect.

Flying Conditions Associated with Cumuliform Clouds. In cumuliform clouds the water drops must grow to considerable size to overcome the resistance of the vertical air currents before they will fall as precipitation. The vertical currents are not constant, but have a gusty character. As a result, cumuliform clouds yield large-drop, showery precipitation. Because of the vertical currents there is a large amount of turbulence, and when icing occurs it may be of the clear or glaze type. Clear ice, as the name indicates, is a clear form of ice that follows the contour of the wings and is difficult to remove. It is, therefore, considered to be the most dangerous type of ice.

Types of Cumuliform Clouds. There are three general types of clouds with vertical development:

Cumulus. (See Figure 1-3.) Cumulus clouds are dense, detached clouds having a flat uniform base. They are dome-shaped and appear rounded, bulbous, or cauliflower-like. The vertical development is usually between 1,000 and 4,000 feet. With bases at 2,000 to 5,000 feet, cumulus clouds are often termed fair weather clouds.

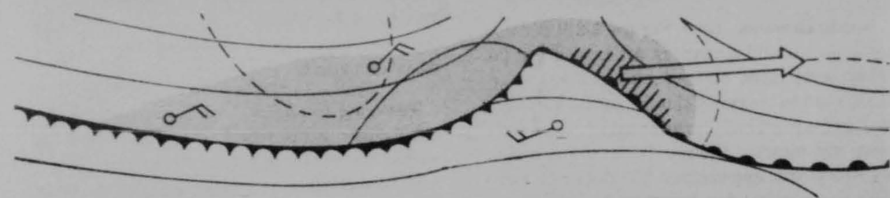
Towering Cumulus. (See Figure 1-3.) Towering cumulus are merely large cumulus with vertical development up to 18,000 feet. Icing may be moderate to severe and is of the clear type. The bases usually run from 2,000 to 5,000 feet. Precipitation does not fall from cumulus clouds, but does fall from well-developed towering cumulus.

Cumulo-nimbus. (See Figure 1-3.) Cumulo-nimbus clouds develop from towering cumulus. They have vertical development up to 30,000 feet or higher. The top is a heavy swelling mass of clouds that usually spreads out into the shape of an anvil. This anvil portion is composed of ice crystals and has a fibrous texture. Cumulo-nimbus are thunderstorm clouds and constitute the most hazardous type of flying weather. Associated with these clouds are violent up and down drafts, heavy rain, or snow, hail, gusty winds at the surface, and thunder and lightning. Thunderstorms have caused many aircraft crashes and should be avoided when possible. These clouds may be found singly, late on a hot summer afternoon, or often in a line along a cold front, or in advance of a cold front as squalls. They also may be formed along a warm front hidden among the warm front system of clouds.

4. VISIBILITY

Visibility is the distance a pilot can see horizontally measured in miles or fractions thereof. When the visibility is more than fifteen miles, it is said to be unlimited. When it is less than three miles, it is generally considered to be a definite hazard and causes instrument flying conditions. The most common restrictions to visibility are fog, precipitation, smoke, clouds, haze and dust.

SECTION III - AIR MASSES AND FRONTS



1. INTRODUCTION

All weather is the result of air masses and their movements. Various types of air do not mix readily. A large mass of warm air will not mix with a large mass of cold air but will have a tendency to overrun the cold air. It is in the boundaries between air masses, known as "fronts," that much of the bad flying weather exists. The study of air masses and fronts is one that is long and difficult. Only the basic principles will be considered in this section.

2. AIR MASSES

An air mass is defined as a large portion of the earth's atmosphere that approximates horizontal homogeniety. It is evident, however, that a mass of air that lies over the Gulf of Mexico for a long period of time will be vastly different from one that has been formed over northern Canada. The air lying over the Gulf will become warm and moist, while that over Canada will become cold and dry. Such regions as those of northern Canada and the Gulf of Mexico which give definite characteristics to an air mass, are known as source regions. Air masses which remain over them for a period of time will develop certain identifying properties and are classified accordingly.

Classification of Air Masses

Air masses are classified according to their source, and characteristics.

Source. Air masses that originate in the arctic fields of snow and ice and the snow covered portions of the continents are known as polar air masses and are symbolized by a large "P." Air masses that originate in the subtropics are known as tropical air masses and are symbolized by a large "T."

An air mass that originates over land is further classified as continental air and has the symbol "c." One that originates over water is known as maritime air and has the symbol "m." Thus an air mass originating over northern Canada would be further classified as continental polar air or "cP," while one originating over the Gulf would be maritime tropical air or "mT" air. See Figure 1-4.

Temperature. An air mass that is warmer than the surface over which it is passing is known as a warm air mass and has as its symbol a small "w." One that is colder than the surface over which it is flowing is a cold air mass symbolized by a small "k." The final classification then of a mass of air originating in northern Canada and flowing over the warmer surface of central United States would be "cPk." The warm, moist air formed over the Gulf, passing over the South Atlantic states, would be "mTw." The cold air mass symbol is shown on a weather map in blue and the warm air mass is indicated in red.

Air masses do not necessarily retain their original classification. A warm air mass moving over a cool surface at night may become a cold air mass moving over the warmer surface on the following day, and the resultant weather will be changed.

Air Mass Weather

Due to the Coriolis force created by the rotation of the earth, all air masses in the northern hemisphere have a general eastward movement. A warm air mass will add a northward component to this movement and a cold air mass originating near the poles will add a southward component. It is this general trend of air mass movements that assists forecasters in predicting future

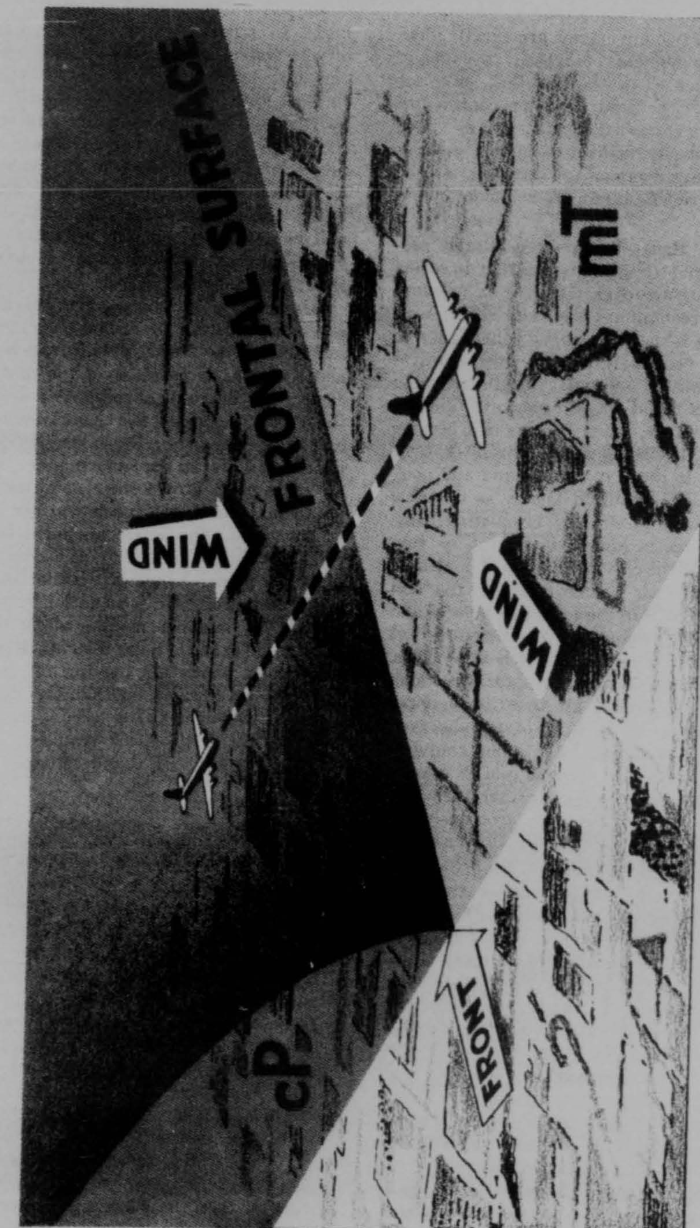


Figure 1-4 Two Air Masses Meeting Along a Front

weather. No two air masses are exactly alike and a large number of types are possible. This is evidenced by the fact that polar air may be of either maritime or continental origin and may be further classified as warm or cold. However, there are certain general characteristics common to warm air masses and there are those that are common to cold air masses.

Cold Air Mass Weather. As stated previously, a cold air mass is one that is cooler than the surface over which it is passing. The most predominant characteristic of such an air mass is that it is unstable in the lower levels. The cooler air passing over a warm surface is heated and will react in the same manner as a liquid placed on a stove. The air near the surface, when heated, will become less dense than the air above it, and will tend to rise. As it rises, it will expand and cool. This creates a condition known as unstable air. The air is constantly circulating, producing up-drafts and down-drafts, or turbulent air. If the cold air mass is of continental origin, the air will be relatively dry and the weather within the area will be cool and clear. If the air mass is of maritime origin it will be relatively humid; if the heating effect is great enough to produce up-drafts which will carry the humid air to great heights, it will condense in the form of cumulus-type clouds or sometimes later even thunderstorms may result. In general, cold air masses are unstable and result in rather turbulent air in the lower levels with good visibility except within cloud formations.

Warm Air Mass Weather. A warm air mass is defined as one that is warmer than the surface over which it is passing. Due to the cooling effect of the surface, the lower layers of air are cooler and therefore more dense than the upper layers. This has a stabilizing effect and warm air masses are, therefore, generally considered to be composed of stable air. Warm air masses that have maritime origin contain large quantities of water, and if the cooling effect of the surface over which it passes is great enough, this moisture will condense in the form of fog or stratiform clouds. This phenomenon explains the presence of fog or low clouds over coastal areas on early mornings following a relatively cool night. In general, warm air masses are relatively stable and humid. Because the air is stable, the elements which restrict visibility, such as dust, smoke, and haze, will remain near the surface and visibility will be poor. If this air is lifted and cooled either by terrain or by overrunning cold air, widespread cloudiness and precipitation will result. In flying through a warm air mass, the air will be relatively smooth, visibility will be poor, and there is always the probability of stratiform clouds and fog.

Air masses do not always retain their same classification. Maritime air which originates over the North Pacific will be lifted and cooled as it passes over the continental divide. Considerable precipitation results on the western slope of the mountains and the air may descend on the other side as dry continental air. In the same manner, a warm air mass moving over the cool waters of the ocean may reach the much warmer surface of the coast. The warm air mass then becomes a cold air mass, and, as a result, there will be a great change of weather in a very short distance. Such a situation is common during the summer months along the east coast of Texas and the Florida Peninsula. The moist warm air moving off the Gulf suddenly becomes cooler than the surface of the land over which it is passing and a very unstable air is produced resulting in large cumulus clouds and thunderstorms.

3. FRONTS

Fronts are defined as a line of discontinuity between two air masses of different temperature and density. There are two main types of fronts, warm fronts and cold fronts. When a warm front and a cold front combine, the result is known as an occlusion or an occluded front. It is rather difficult to visualize a frontal surface. Generally, as previously mentioned, warm air masses originate in the tropics and in the northern hemisphere and move northward. At the same time cold air masses move southward. Sooner or later the two must meet; and, when they do, they do not readily mix, and each air mass remains intact. The surface which separates the two is called a frontal surface. Since the cold air is heavier than the warm air, it permits the

RESTRICTED

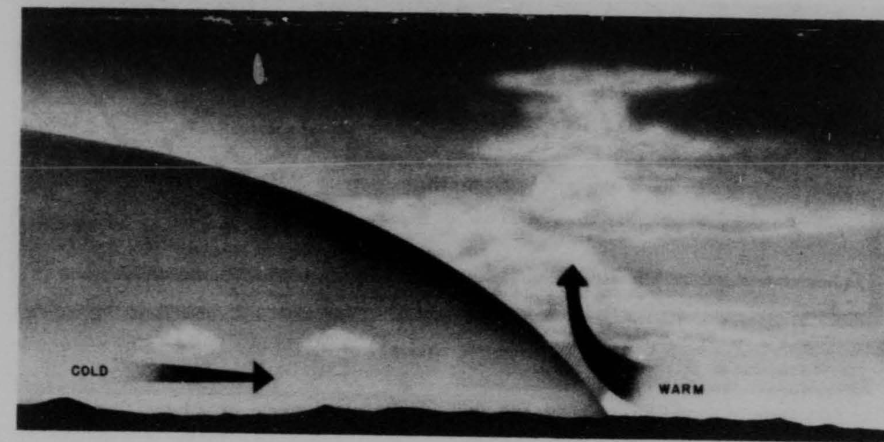

Figure 1-5 Cold Front

warm air to slide up over it, whether or not the cold air is advancing or retreating. Thus, the frontal surface is never vertical, but slopes over the cold air.

Cold Fronts

If the cold air invades the region occupied by the warm air, it will wedge under the warm air, pushing it upward. In this case the frontal surface is known as a cold front. No two cold fronts are exactly alike, but all have certain common characteristics:

As indicated in Figures 1-5 and 1-6, the cold air moving in under the warm air lifts the warm over it. Due to the friction of the earth on the forward edge of the cold front, the forward edge tends to be retarded and the slope of the front is relatively steep. The warm air is lifted rather abruptly over this steep slope causing it to expand and cool very rapidly. This results in an unstable condition,

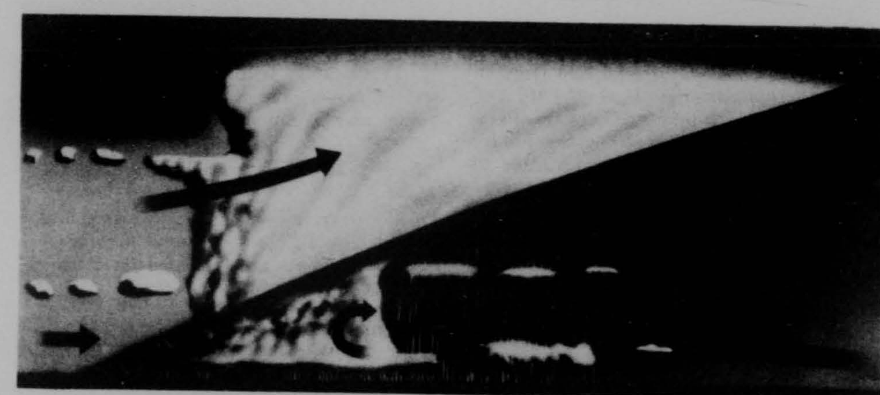

Figure 1-6 Warm Front

THIS PAGE IS DECLASSIFIED IAW EO 13526

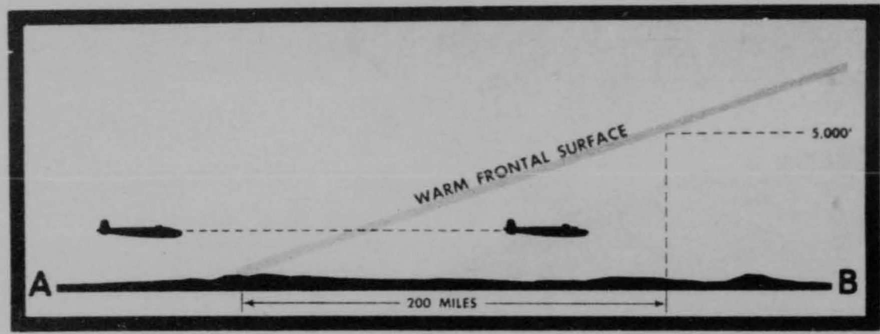

Figure 1-7 Warm Front

the formation of cumuliform clouds, and, in most cases, precipitation. As a general rule, there will be a line of storm clouds along the cold front. In a rapidly-moving cold front this line of instability may extend in advance of the cold front, producing a second line of storm clouds known as a squall line.

Because the slope of the front is steep, the weather bank associated with the front is relatively narrow; it will be found at or immediately following the front, and will clear rather rapidly behind it.

A third identifying feature of the cold front is that as it passes, a sharp decline in temperature will be noted.

The winds behind a cold front will usually shift in a clockwise direction.

The cold front will extend south and west from the area of lowest pressure.

The general movement of a cold front in the northern hemisphere is southward and eastward. Cold fronts are drawn on a weather map in a solid blue line. See Figure 1-4. Generally speaking, it is advisable to avoid flying through a cold front whenever possible. However, if it becomes necessary to do so, the flight path should be perpendicular to the front so as to pass through it in the least amount of time.

Warm Fronts

When warm air is replacing retreating cold air, the frontal surface is known as a "warm front." Some of the identifying characteristics are as follows:

Because the cold air is retreating, the frictional force of the earth's surface on the trailing edge of the cold air retards its progress and causes the frontal surface to be relatively flat. As indicated in Figure 1-7, the slope of the warm front is very gentle. The gentle lifting and cooling of the lower portion of the warm air as it overruns the cold air below generally has a stabilizing effect on the warm air mass in much of the same manner as a warm air mass passing over any cool surface. The resultant weather consists of a wide band of stratiform clouds and precipitation far in advance of the front, with ceilings becoming lower as the front approaches. Warm front weather will often extend as much as 500 miles in advance of the front, but is less severe than cold front weather.

Temperature will increase when a warm front passes, and a slight clockwise windshift may be noted.

The greatest hazards to flying in warm front weather are low ceilings and poor visibilities.

Warm fronts extend southward and eastward from the area of lowest pressure.

Warm fronts are indicated on a map by a solid red line.

Occluded Fronts

It has been stated previously that warm fronts extend south and east from the area of lowest pressure and cold fronts extend

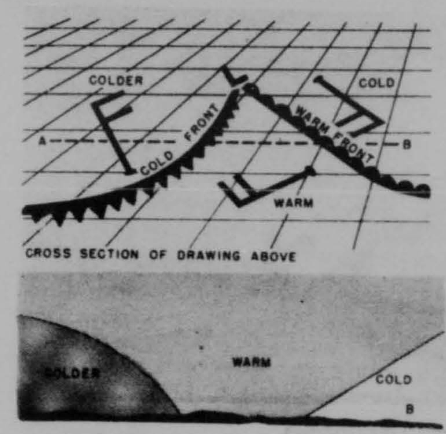

Figure 1-8 Meeting of Warm and Cold Fronts

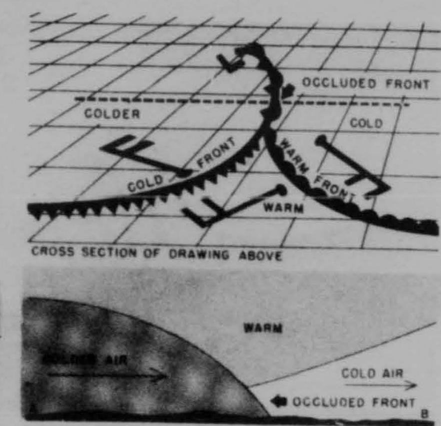

Figure 1-9 Occluded Front

south and west from the area of lowest pressure. This would indicate that there is a point where the warm front and cold front meet. (See Figure 1-8.)

The circulation of air around a low pressure area is cyclonic or counterclockwise. The more rapidly moving cold front tends to catch up with the slow moving warm front, resulting in the formation of a wave.

or an occluded front. (See Figures 1-9 and 1-10.)

Most occlusions are accompanied by extensive cloud cover. (See fiigure 1-10.)

Occlusions have either cumuliform or stratiform types of clouds. Moderate to heavy turbulence may be expected in flying through one. (See Figures 1-10 and 1-11.)

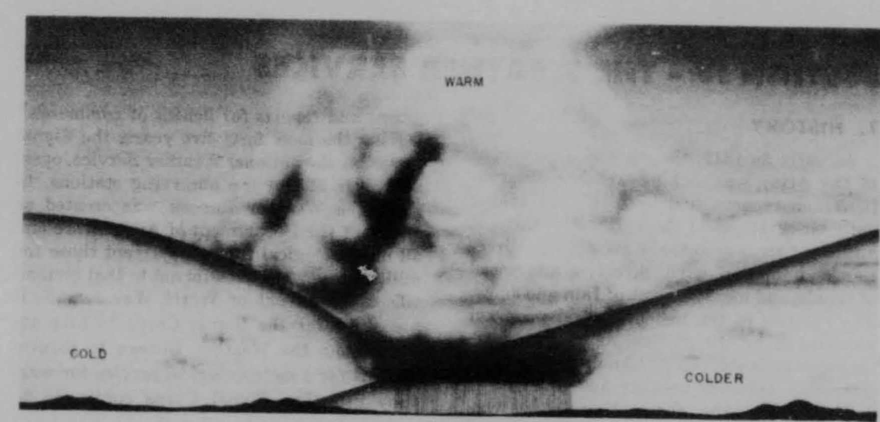

Figure 1-10 Warm-Type Occlusion

Figure 1-11 Cold Front Type Occlusion

Precipitation in the form of rain, snow, or drizzle is common both in advance of and behind the front.

Low ceilings and fog are common in advance of the front.

It is at the point where the cold front first overtakes the warm front that weather will be most severe.

Occlusions are drawn on a weather map in a solid purple line.

Stationary Fronts

There are times when the atmospheric pressure is such that a front apparently will cease to move. Such a front is known as a "stationary front." The warm air in such a front is lifted very gradually and as a result the weather associated with it is not severe. This type of front is indicated on a map by a broken red and blue line.

SECTION IV - THE WEATHER SERVICES

1. HISTORY

As early as 1819, the medical department of the Army was making weather observations and reports, and by 1843 was taking daily observations of the barometer, the wet and dry thermometer, sky conditions, direction and force of wind, direction and speed of clouds, and measurement of rain and snow. The purpose of the meteorological program undertaken by the medical department was to promote better understanding of the relationship between weather and disease.

The first weather forecasting service was created in 1870 and assigned to the Signal Corps of the Army as "the division of telegrams and reports for benefit of commerce." During the next forty-five years, the Signal Corps, as the national Weather Service, operated over 225 of the observing stations. In 1890, the Weather Bureau was created as a part of the Department of Agriculture and all meteorological functions except those for military use were transferred to that civilian office. The advent of World War I made it necessary for the Signal Corps to take experts from the Weather Bureau to form a nucleus for a meteorological service for wartime use. The Signal Corps continued to operate this activity after World War I and provided this service for the Air Corps which

had become by far the largest user of the Signal Corps weather service. On 1 July 1937 the War Department General Staff transferred the weather service from the Signal Corps to the Air Corps.

Air Corps Control

With this transfer, the Air Corps became responsible for providing such weather services as it might need and for furnishing weather forecasts to army headquarters at division levels and higher. All other weather needs for the Army were the responsibility of the arms and services concerned.

The responsibility for the development, procurement, stowage, and issue of meteorological equipment remained with the chief signal officer. He was also made responsible for providing teletype machines and any other communications equipment which might be required for various weather stations.

With the entry of the United States into the war in 1941, the problem of providing an adequate weather service to the various users exceeded any previous estimates. Few weather observations were available to our forecasters for air operations in Africa, South America, Alaska, and the Pacific Islands. It became necessary for the AAF to establish its own weather service in those areas.

By the spring of 1942, the Army Air Force Weather Service had grown to be a world-wide organization. It published information for flight training, air transport, strategic and tactical air operations, and general military planning. It continued to grow throughout the war, reaching a peak strength of nearly 19,000 persons manning approximately 900 weather stations, more than two-thirds of which were in 58 foreign countries.

Extension of Service to Non-Air Corps Troops

In the fall of 1942, the Army Air Force Weather Service extended its services to Army Ground and Service Forces, neither of which was equipped to furnish extensive weather information for itself.

In May 1945, Army Regulation 95-150 was revised to make the Commanding General, AAF, responsible for furnishing weather in-

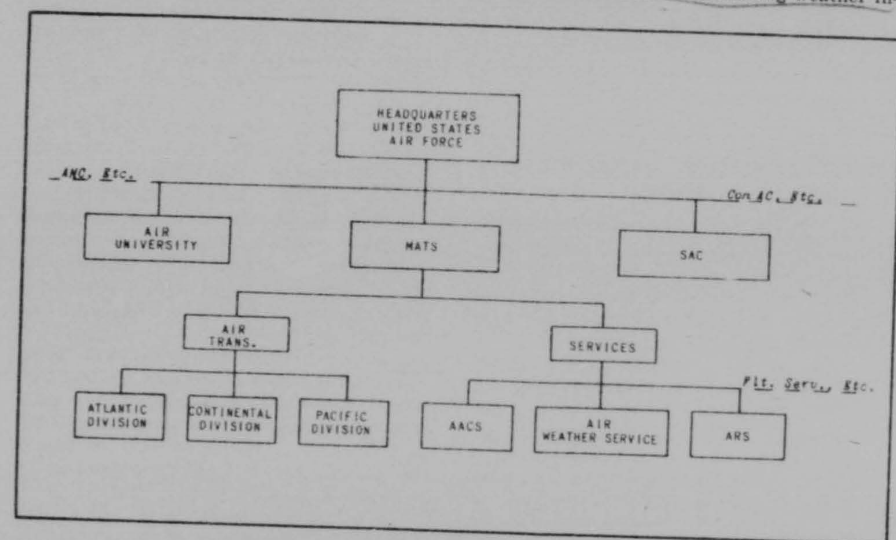

Figure 1-12 Military Air Transport Service

THIS PAGE IS DECLASSIFIED IAW EO 13526

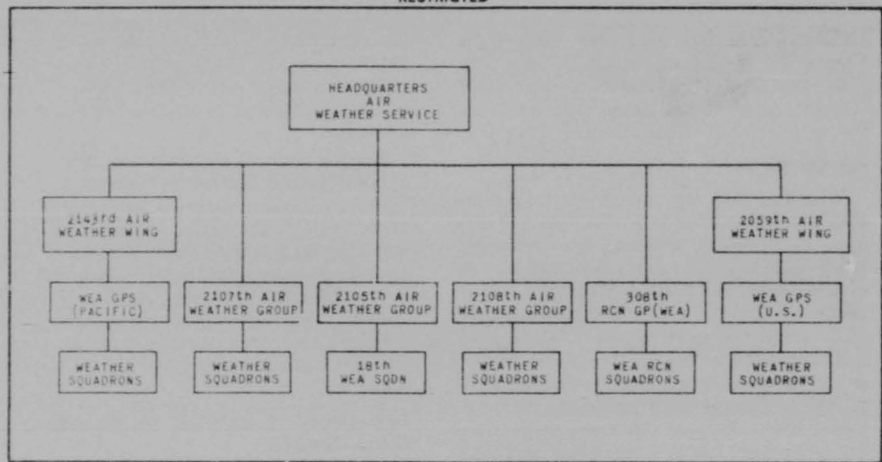

Figure 1-13 Headquarters Air Weather Service

formation to all components of the Army except those which might be specifically exempted by the War Department. Some of the arms and services specifically exempt are the Chemical Corps, the Field Artillery, the Coast Artillery, and the Anti-Aircraft Artillery. This responsibility for provisions of the military weather service still rests with the Air Weather Service in spite of the acquisition of autonomy by the United States Air Force in September of 1947.

2. ORGANIZATION OF THE AIR WEATHER SERVICE

The Air Weather Service now occupies the position in the United States Air Force structure as shown in Figure 1-12.

Figure 1-13 shows the internal organization of the Air Weather Service. It should be noted that below headquarters, Air Weather Service, a vertical command structure extends through wings, groups and squadrons to the lowest element, the weather detachment. In addition to these weather units, which provide weather observation and service essentially confined to land masses, there exist units within the Air Weather Service whose mission includes the provision of "very long range" aerial weather reconnaissance over the otherwise inaccessible areas of the oceans and ice caps.

Primary Functions

The primary functions of the Air Weather Service are to make observations of the weather, to report these observations, to prepare weather forecasts for flights of military aircraft and for all other military operations as requested, as well as to prepare climatic studies of any or all parts of the world as requested. In the United States, this service normally is performed at fixed installations at operating Air Force bases. In a theater of operations, this fixed weather service is likely to be supplemented by mobile weather stations which will move with changing tactical situations to provide weather service as required by Air Force and Army operations, and air transportable weather stations which will be flown into forward air locations.

Figure 1-14 shows the geographical boundaries of the units of the Air Weather Service. If a more thorough study of the organization responsibilities and procedures of the Air Weather Service is desired, the following regulations are listed for reference:

Army Regulation 95-150.
Air Force Regulation 20-44.
Air Force Regulation 20-58.
The 105 series of Air Force Regulations.

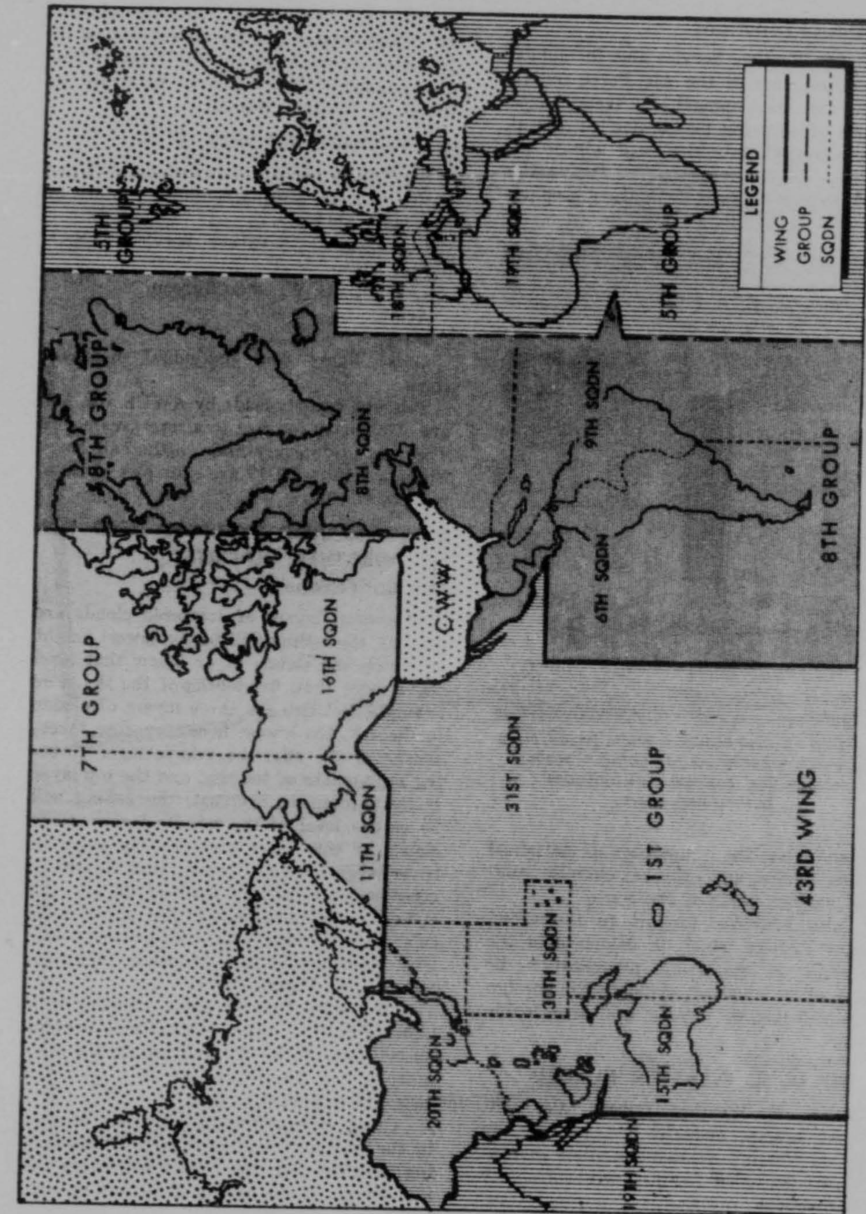

Figure 1-14 Geographical Boundaries of the Units of the Air Weather Service

THIS PAGE IS DECLASSIFIED IAW EO 13526

Additional Functions

The Air Weather Service also formulates the requirements of the Air Force for research and development in instrumental methods of securing meteorological and allied geophysical data that will add to the knowledge of the workings of the earth's atmosphere upon which military applications must be based.

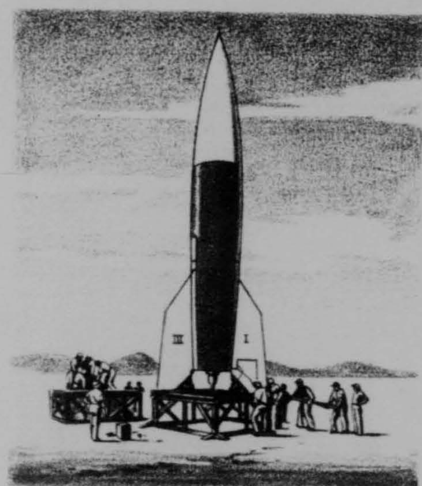

Figure 1-15 Rocket Firing at White Sands, N. M. Rockets are being used to obtain weather information from extreme altitudes in the atmosphere.

It supervises the compilation of statistical weather studies and prepares climatic studies of various parts of the world.

It also provides support to the Cloud Physics Project which is determining the feasibility of procuring precipitation by means of inoculating clouds with foreign substances such as "dry ice" and silver iodide crystals.

3. THE U. S. WEATHER BUREAU

The U. S. Weather Bureau, the civil weather agency, must by law, provide the National Weather Service and other government meteorological facilities with such basic meteorological information normally required in their operations. The meteorological facilities operated and the meteorological information provided by the Air Weather Service augments that which is furnished by the U. S. Weather Bureau.

4. WEATHER REPORTS

Reports are made in the continental United States, Alaska, and surrounding waters by five main agencies.

(AWUS) Air Weather Service (USAF Bases).
(AW) U. S. Weather Bureau.
Army.
Navy.
Coast Guard and individual merchant ships.

Teletype reports made by AWUS and AW are of primary interest to aircrew members. They are made every hour on the half hour. Figures 1-16 and 1-17 are examples of these reports.

5. CODES AND SYMBOLS USED ON WEATHER REPORTS

Sky Conditions

If several layers of scattered clouds are present, the ceiling will be the lowest height at which the clouds at or below that level cover more than five-tenths of the sky. For example, if there are three layers of clouds in the sky, the lowest layer covering three-tenths of the sky, the middle layer covering four-tenths of the sky, and the top layer being a complete overcast, the ceiling will be at the level of the middle layer as the clouds of this layer and the one below it cover seven-tenths of the sky. Had the middle layer covered only one-tenth of the sky, the ceiling would have been at the upper overcast layer, as the total cloudiness at any level below would have been less than five-tenths. (See Figure 1-18.)

If fog, dust, blowing snow, blowing dust, blowing sand, or other obstructions prevent observation of the sky and reduce the visibility to less than one-fifth of a mile, the ceiling is reported as zero.

Ceiling is reported in hundreds of feet in the teletype weather report. If the ceiling is 8,500 feet, the report will carry the number 85. If the ceiling is 50 feet or less,

Figure 1-17 U. S. Weather Bureau Teletype Report (C.A.A. Circuit.)

THIS PAGE IS DECLASSIFIED IAW EO 13526

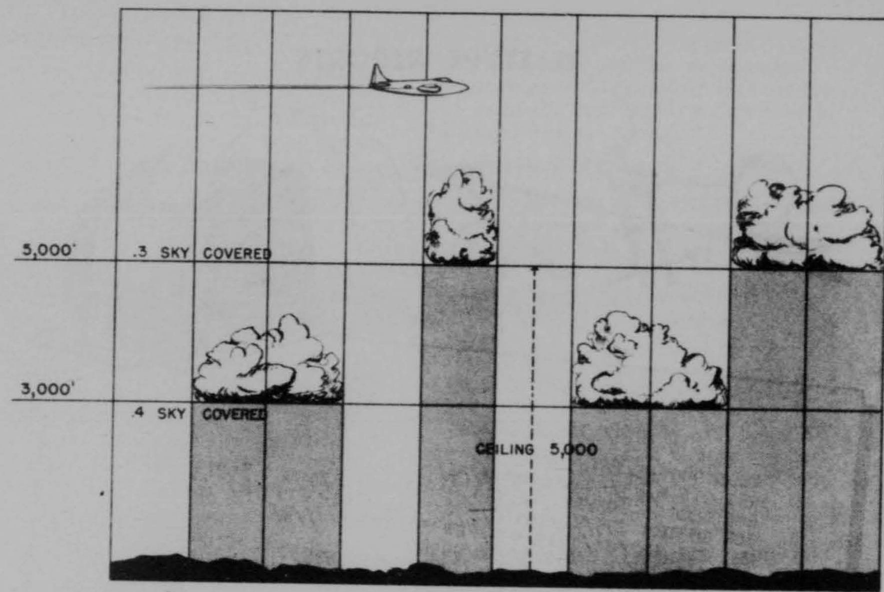

Figure 1-18 Definition of Ceiling Cover

it will be reported as zero and the figure "0" sent on the report. If the height is estimated rather than measured, the letter "E" precedes the elevation. For example, if the ceiling is estimated at 600 feet, the report will be "E6." If the ceiling is unlimited, this element of the report is omitted.

Report of Cloudiness

This consists of two phases, the first dealing with the types of sky conditions; the second, with the height of the cover above the surface of the earth.

Types of Sky Conditions

In making observations and reports the following symbols and words are used to describe the types of sky:

○ Clear; no clouds or less than one-tenth of sky covered by clouds.

⦶ Scattered; one-tenth to five-tenths, inclusive, of sky covered by clouds.

⦷ Broken; more than five-tenths but not more than nine-tenths of sky covered by clouds.

⊕ Overcast; more than nine-tenths of sky covered by clouds.

These observations always are taken at a point from which the entire sky may be viewed, and then the number of tenths of sky covered by the clouds is reported in one of the above terms as based on the entire dome of the sky.

Complete Cloud Report

With the above symbols, two separate layers of clouds may be reported in this section of the report If there is a layer of scattered clouds below the ceiling, the height of that layer will be indicated before the "scattered" symbol in hundreds of feet except when there are two layers of scattered clouds, in which case only the height of the lower layer will be shown. The following examples will illustrate the methods of reporting various types of cloud decks:

30 ⦷ ⦷ reports a 3,000-foot ceiling with a higher layer of broken clouds. 30 indicates that the ceiling is the base of the lower layer

of broken clouds. The word "broken" means that the layer covers more than five-tenths of the sky. The upper layer of broken clouds is at a height somewhere above 3,000 feet.

30 ⊕ ⦷ reports a 3,000-foot ceiling and lower broken clouds, with a higher overcast deck. The overcast layer is above 3,000 feet and the broken layer which determines the ceiling is at 3,000 feet.

30 ⊕ 15 ⦶ reports a 3,000-foot ceiling, overcast, and with lower scattered clouds at 1,500 feet. The overcast layer is at 3,000 feet.

Visibility

Visibility is the mean greatest distance toward the horizon that prominent objects such as mountains, buildings, towers, etc., can be seen and identified by the normal eye, unaided by optical devices; this identification must be possible over a range of more than half the horizon.

Visibility is measured by visual observation, noting the distance at which objects blend into their surroundings. Each observation station has on hand a table of checking points showing the distances of objects surrounding the station. At night, unfocused lights are observed as well as prominent objects against the sky.

Visibility is reported directly in miles and fraction of miles. A fluctuating visibility is indicated by entering the letter V immediately after the report. These examples illustrate the reporting of visibility.

5 indicates a 5-mile visibility.

1¼ indicates a 1¼-mile visibility.

½ V indicates a ½-mile visibility, fluctuating about this value.

X ½ F indicates obscured sky, visibility ½-mile with fog.

6. SPECIAL WEATHER CONDITIONS

This group includes reports of all thunderstorms, squalls, precipitation and restrictions to visibility. Descriptions of each condition and the codes for reporting are given below.

Thunderstorm (reported T). A thunderstorm is reported whenever thunder can be heard. If the storm is especially severe, with wind speeds of over forty miles an hour and incessant loud thunder, the storm is classified as heavy (reported T+).

Rain is a fall of liquid drops of water having a greater diameter than 1/50 inch. Rain may be classified as light, moderate, or heavy (reported R-, R, R+ respectively), depending upon the rate of accumulation of water in inches or fractions of inches in a given time.

Freezing Rain (reported ZR-, ZR, ZR+). Freezing rain is rain which freezes instantly upon striking objects in the open. It is classified in the same manner as rain.

Drizzle (reported as L-, L, L+). Drizzle is a fall of very fine drops of liquid water. These drops seem to float in the air. Their diameter is less than 1/50th inch and fall slower than ten feet per second. Drizzle is classified as light, moderate, or heavy by the degree to which it limits the visibility and not by the rate of accumulation of water on the ground.

Freezing Drizzle (reported ZL-, ZL, ZL+). Drizzle which freezes instantly upon impact with objects in the open is a freezing drizzle. It is classified in the same manner as drizzle.

Snow (reported S-, S, S+). Snow is a fall of white or translucent ice crystals in branched hexagonal shapes. Snow is classified as light, moderate, or heavy, by the degree to which it alone limits the visibility while falling.

Sleet (reported E-, E, E+). Sleet is a fall of transparent, globular grains of ice ranging from 1/25 to 4/25 inch in diameter. It is formed by the freezing of rain drops before they reach the ground. Sleet is classified as light, moderate, or heavy, depending upon the rate of accumulation on the ground.

Hail (reported A-, A, A+). Hail is the fall of ice balls, or stones, with diameters ranging from 1/5 inch to 2 inches or more. They may be either quite transparent or composed of alternate layers of clear and opaque ice. Hail occurs almost exclusively in violent and prolonged thunderstorms. It is classified as light, moderate, or heavy, depending upon the rate of its accumulation on the ground.

Snow Pellets (reported SP-, SP, SP+). Snow pellets are white opaque grains having a snowlike structure. They are usually crisp

THIS PAGE IS DECLASSIFIED IAW EO 13526

and easily compressed. They rebound and often burst when striking hard ground. Snow pellets fall almost exclusively in showers.

Small Hail (reported AP-, AP, AP+). Small hail is a fall of semi-transparent grains of frozen water, usually with a soft center and a thin, wet layer of ice around the outside, which gives a glazed appearance. It is classified in the same manner as hail.

Showers (reported RW-, RW, RW+), snow reported (SW-, SW, SW+). Showers of either rain or snow occur when the precipitation is of a highly variable character, alternately starting and stopping within 15 minute intervals. They are classified in the same manner as rain or snow, respectively.

Dry Haze (reported "H"). Haze is a suspension in the air of extremely fine particles of dust or other particles which may reduce the visibility quite appreciably. It gives a characteristically dirty appearance to objects at a distance.

Fog (reported "F"). Fog is a suspension in the air of water particles condensed from the vapor state. It is classified in intensity by the degree to which it limits visibility.

Ice Fog (reported "IF"). Ice fog occurs when the particles are ice instead of liquid water.

Ground Fog (reported "GF"). Ground fog occurs only in a shallow layer, so that the sky is visible from the ground. It is reported in the same way as fog.

Smoke is reported as "K" when it reduces visibility.

Dust is reported as "D" when it is distributed in the atmosphere.

Blowing Dust (reported "HD"). When dust is picked up from the surface and blown about in clouds or sheets at low levels above 6 feet, it is reported in the same way as dust.

Blowing Sand (reported "BN"). When sand is picked up locally by the wind and blown about in thick concentrations, it is classified in the same way as dust.

Blowing Snow (reported "BS"). When the snow is not actually falling but is picked up from the surface and blown about in clouds or sheets six feet or more above the surface, and reduces visibility, it is reported as blowing snow. It is classified in the same manner as snow.

7. PROPERTIES OF AIR

General

Air properties may be easily identified in the report by three groups of figures separated by slant marks such as 091/53/45. The first of these is the barometric pressure at sea level in millibars, the second is the temperature of the air, and the third is the dew point.

Barometric Pressure

Pressure may be defined as force exerted on a unit area of surface by a fluid under compression. At sea level, the atmosphere exerts a pressure of about fifteen pounds per square inch. The atmosphere may be thought of as a sea of air with the land and ocean surfaces at its bottom. In the same way that a sea of water exerts an increasing pressure with depth, the pressure exerted by the atmosphere is greater at low elevations than in the upper atmosphere. The pressure of the atmosphere is a result of the weight of the air above that point. With increasing elevation, the weight of atmosphere above a specified point will decrease, and, therefore, the pressure in the atmosphere consistently decreases with increasing height.

The pressure exerted by the atmosphere at sea level does not remain constant. It has been found that variations of as much as 4 per cent above the average and 5 per cent below occasionally will be found. Certain characteristics of barometric pressure have been found to accompany special types of weather phenomena. For this reason, weather forecasters require a knowledge of the pressures that exist over large areas on the map. Barometric pressure is included in practically every type of weather report sent out.

To facilitate their calculations, weather men for several years have used a unit called the "millibar" instead of inches of mercury to indicate atmospheric pressure. Normal atmospheric pressure at sea level is 29.92 inches of mercury, or 1,013.2 millibars. This pressure is given in units and tenths of a millibar, but in reports, only the last three digits of the complete pressure number are sent. For example, a pressure of 1,008.8

millibars would be reported 088. There will be no confusion as to whether the pressure is above or below 1,000 if one remembers that the pressure practically never drops below 950 or rises above 1,050 millibars. A report of 751 could not mean a pressure of 1,075.1 (this would be an improbable high value) but would indicate pressure of 975.1 millibars.

Temperature

Temperature of the surface air is measured by means of an ordinary thermometer kept in the shade. Temperature reports are made directly in degrees Fahrenheit in English-speaking countries, elsewhere in degrees centigrade.

Dew Point

Dew point is an indication of the amount of water vapor in the air. It is defined as that temperature to which the atmosphere must be cooled before water vapor will condense from the air. The dew point is a very important factor in predicting the formation of fog, clouds, and precipitation, as all of these form by condensation of water from the air.

Complete Report of Properties of Air

The following examples illustrate the decoding of this group:

REPORT	PRESSURE
891/44/44	989.1 mb.
091/95/76	1,009.1 mb.
452/-20/-35	1,045.2 mb.

TEMPERATURE	DEW POINT
44°F	44°F
95°F	76°F
-20°F	-35°F

8. MISCELLANEOUS DATA

Winds

Wind may be defined as air moving horizontally across the earth's surface. Winds are found throughout the atmosphere, both at the surface and at upper levels. Reports of winds include an indication of both direction and speed of the air movement.

The direction of a wind is that from which it is blowing. For instance, air movement from the northeast toward the southwest would be a northeast wind. Sixteen points of the compass may be used—north, north-northeast, northeast, east-northeast, east, etc. Airway teletype reports indicate wind direction by means of small arrows which may be thought of as flying with the wind. Only eight arrow symbols are found on teletype machines, so it is necessary to use two arrows to indicate intermediate directions. The following examples illustrate the method of reporting wind direction:

WIND	REPORT
North	↓
North-Northeast (Combination)	↓↙
Northeast	↙
East-Northeast (Combination)	←↙
East	←

Wind speed is measured and reported by airway weather stations in knots. Another system of reporting wind speeds, the Beaufort scale (see Section V), is used by Weather Bureau stations in the 6-hourly reports used for forecasting purposes. The wind speed in knots is entered directly after the wind direction arrow, or arrows in the airway teletype report. If the wind is of a gusty character, it may be indicated by the addition of a plus or minus sign immediately after the wind speed. If the peak speed of these gusts is **twenty-five miles per hour (twenty-two knots)** or greater, the gusts are said to be "strong" and are indicated by a plus sign; if the peak speed is from nineteen to **twenty-four miles per hour**, they are said to be "fresh" and are indicated by a minus sign. The absence of a plus or minus sign indicates the wind is "steady." If the air is calm, the letter "C" is sent.

Wind Shifts. If there has been a pronounced shift in the wind direction which may have special significance, it is reported immediately following the other wind data. This report consists of a wind arrow (to sixteen points of the compass) showing the former direction and the time that the shift occurred. Intensity of the shift may be indicated by the addition of a plus or minus sign, minus indicating a mild shift, no sign a moderate shift, and a plus sign a severe shift.

Complete Wind Data. The following examples illustrate the decoding of wind data in the teletype report:

REPORT	*WIND DATA*
↑ 5	South wind, 5 miles per hour.
↓↙ 25+	North-northeast wind, 25 miles per hr. strong gusts.
↘45+ ↑ 1634C+	Northwest wind, 45 miles per hour, strong gusts, wind shifted severely from the south at 4:34 PM Central Standard Time.
C	No wind (calm)

Altimeter Setting.

The altimeter on an airplane is a sensitive aneroid barometer, or pressure measuring instrument. Its principle of action depends upon the decrease of pressure with elevation. Where the pressure is high, as at sea level, the altimeter reads low elevation; and at high elevations where the pressure is low, the altimeter indicates high altitude. Such an instrument will be in error every time the temperature or barometric pressure changes. Modern altimeters are designed to be set by hand to compensate for errors caused by variations in local barometric pressure. The setting number for correction of a station, called the "altimeter setting," is given in the teletype report immediately following the wind data. When the altimeter is set by this number, it will show the correct elevation above sea level when landing at the field. The setting applies only to that field from which the report was sent. The latest correct altimeter setting should be obtained for each field at which it is desired to land. The setting number is in inches of mercury and averages about 29.92 As with barometric pressure, only the last three digits of the complete number are sent, the decimal point being left out. The following examples illustrate how to decode altimeter setting reports:

REPORT	SETTING
990	29.90 inches of mercury
895	28.95 inches of mercury
045	30.45 inches of mercury

Additional Remarks

Often there is some special weather information which the weather observer wishes to send in the report in addition to that provided for in the regular code. In this case, remarks are made at the end of the report in standard abbreviations and symbols. A few of the most important common abbreviations are listed below:

ALT	Altitude
ARV	Arrive
BINOVC	Break in overcast
BRK	Break
BRONO	Broadcast not operating
BROOK	Broadcast operating normally
CHG	Change
CIG	Ceiling
CLD	Cloud
CLR	Clear
CU	Cumulus (cloud)
DRZL	Drizzle
ETA	Estimated time arrival
FANOT	Fan-type marker not operative
FCST	Forecast
GNDFG	Ground fog
HZY	Hazy
ICG	Icing
IFR	Instrument flight rule
IOVC	In overcast
IPV	Improve
LTNG	Lightning
MDT	Moderate
MSL	Mean sea level
MSTK	Mistake
NOOPV	Not operative
OBSC	Obscure
OTP	On top
OVC	Overcast
OVR	Over
PCPN	Precipitation
PIBAL	Pilot balloon sequence reports (upper winds)

PPINR	No personnel to operate radar set
RAGOK	Radio range operating normally
RAOBS	Radio meteorological soundings
RANOT	Radio range reported as unreliable
RGD	Ragged
RNWY	Runway
RTE	Route
SCTD	Scattered
SNW	Snow
SQAL	Squall
STM	Storm
STN	Station
THD	Thunderhead
THDR	Thunder
THK	Thick
THN	Thin
TLTP	Teletype
TMP	Temperature
TOVC	Top of overcast
TSTM	Thunderstorm
TURBT	Turbulent
UNSTDY	Unsteady
VFR	Visual flight rule
VSB	Visible
VSBY	Visibility
WND	Wind
WB	Weather Bureau
XLNT	Excellent
XTSV	Extensive
ZONOT	Station location marker, ultra high frequency not operating

The above short list includes many of those abbreviations commonly found in weather reports. Many others are used, but they are usually more obvious and can be translated at sight. The following examples illustrate the use of abbreviations in weather remarks:

"PIREPS ICG 15-75 N FW 55-80 MSL": Pilot reports icing 15 to 75 miles north of Fort Wayne at 5,500 to 8,000 feet above mean sea level.

9. TERMINAL FORECAST CODE GROUP

This group of symbols is placed at the end of each AWUS sequence and indicates the forecast for a period of twelve hours from the time of the sequence.

See below the solved forecast for RME Rome AFB.

10. DECODING OF COMPLETE REPORTS

Solved Examples

The following teletype reports have been decoded as examples:

(1) RME 40 ⦶ 15 + 207/17/3→4/011/- RAREP PPINR/35940 35913 99940
Rome A.F.B. 4000′ scattered clouds, visibility over **15 miles,** barometric pressure in millibars 1020.7, temperature 17°F., dew point 3°F, wind west, 4 knots, altimeter setting 30.11 in. of mercury, no personnel to operate radar set. 4 hrs. from time of hourly forecast ceiling will be 3500′, visibilty **9 miles,** no weather. In 5 hours from time of hourly forecast ceiling will be 3500′, visibility **9 miles** and strong, gusty, surface winds. In 9 hours the ceiling will be unlimited, visibility 9 miles, no weather.

**Where the number 9 is used in place of the ceiling height this indicates a ceiling over 9,750 feet.

(2) SWF WO x 1/2F 149/22/21 19/995/
Stewart AFB indefinite ceiling, sky obscured by fog, visibility ½ mile, fog, barometric pressure in millibars, 1014.9, temperature 22°F, dew point 21°F, wind north northeast, nineteen knots, fresh gusts, altimeter setting, 29.95 inches of mercury.

SECTION V - THE WEATHER MAP

1. INTRODUCTION

In any type of study, there is usually one report, chart, diagram, or some other device that indicates the over-all results of the study, a culmination of effort, so to speak. The student taking a master's degree writes

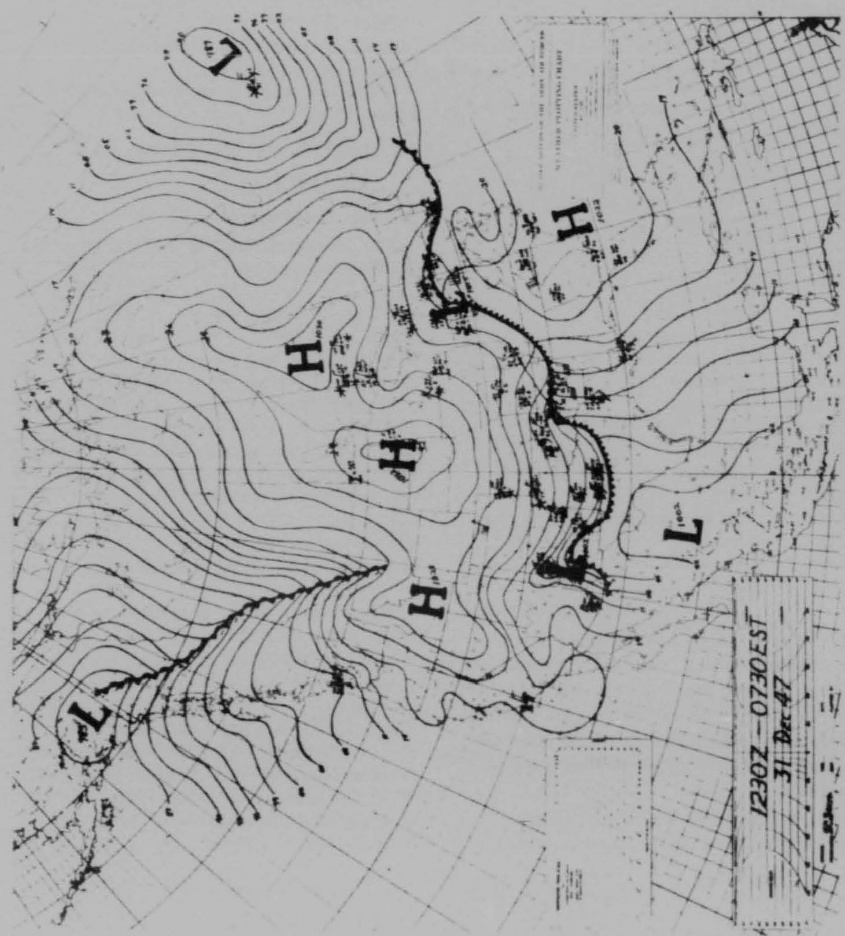

Figure 1-19 Synoptic Weather Map

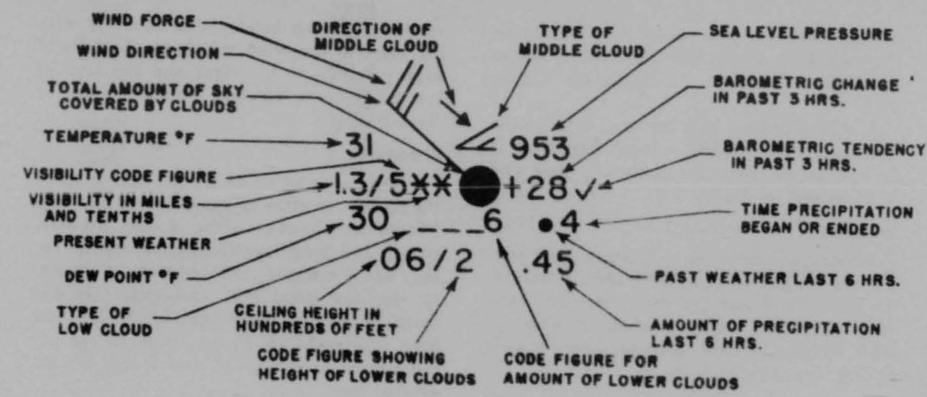

Figure 1-20 Station Circle

a thesis; the investigation board makes a report of its findings, and the statistician draws a graph depicting the results of his figures. In weather reporting and forecasting this final report appears in the form of a "weather map."

A weather map is a map of a given area which indicates all of the weather conditions in that area including the past six hours and present weather conditions at all of the reporting stations, location and type of fronts, precipitation and restriction to visibility, surface winds and atmospheric pressures. These weather conditions are shown in much the same manner that topographical conditions are shown on a relief map.

Beaufort Scale of Wind Force

BEAUFORT NUMBER	WEATHER MAPS	DECODE WIND DIRECTION	WIND SPEED MPH
0		CALM	LESS THAN 1
1			1 TO 3
2			4 TO 7
3			8 TO 12
4		S	13 TO 18
5			19 TO 24
6			25 TO 31
7			32 TO 38
8			39 TO 46
9			47 TO 54
10		NNE	55 TO 63
11			64 TO 75
12			ABOVE 75

Figure 1-21 Beaufort Scale

2. PREPARATION

Weather maps are prepared four times daily, once every six hours, and often are referred to as the six-hour weather maps. A special coded report is gathered from each station in the North American area to be included on the map and redistributed in such a manner as to allow each station to have a complete set of reports. These reports are then plotted on a blank map, and the forecaster will add other details such as fronts, highs, and lows. The finished product is known as a synoptic map, as shown in Figure 1-19. Many times a forecaster will draw a map in which he depicts the situation as he forecasts it six or twelve hours hence. Such a map is called a prognostic map.

3. WEATHER MAP INFORMATION

As previously stated, the weather map depicts most of the information gathered in the weather office.

Station Circle

The station circle shows weather information past and present as it is plotted on the map. This information is plotted by means of certain symbols as indicated in Figure 1-20.

It will be noticed that the wind is indicated by a symbol similar to a small flag. This is known as the Beaufort scale of winds and is explained in Figure 1-21.

Isobars

Isobars are lines on a weather map connecting points of equal sea level pressure. An isobar is drawn for each three millibars of pressure and indicates pressure levels in the same manner that contour lines indicate altitude on a relief map.

Highs and Lows

It will be noted on the map that the isobar indicating the highest pressure completely surrounds the point having a relatively high pressure. This point would be the center of an air mass and is known as a "high." The air flows around these highs in circular clockwise manner and they are often referred to as "anticyclones." Because the air tends to descend and move outward from a high, the air is relatively stable and good flying weather prevails.

It also will be noted that the isobar indicating the lowest pressure in a system completely surrounds an area of relatively low pressure. This area is known as a "low." As would be expected in such a differential of pressure, air tends to move toward the center of a low and does so in a counter-clockwise circular manner. This circulation of air is known as a cyclone, or a cyclonic storm, and should not be confused with the smaller twisters properly termed tornadoes. Cyclones are usually hundreds of miles in diameter. Because the air within a low is ascending slightly, it is relatively unstable and poor flying weather prevails. Lows are indicated on weather maps by a large "L." If possible, this "L" is entered in red. Highs are indicated by a large "H" in blue.

As indicated by the wind at various places along isobars on the illustrated map, the wind does not blow directly across the isobars from the highs to the low, but more or less flows parallel to them. This again is due to the Coriolis force. For this reason, a person on the northern hemisphere standing with his back to the wind will have the area of high pressure to his right and the area of low pressure to his left. This is known as Buys-Ballott's law.

Fronts

Fronts are plotted on the weather map by the forecaster after he has observed the map. Fronts are located along a low pressure trough and their identification as to whether they are a warm or cold front is determined by the dew point and temperature behind them. It will be noted that in the weather map illustrated in Figure 1-19, fronts are not drawn in color, but cold fronts are indicated by:

 and warm fronts by:

. On such a map occlusions are indicated by a line:

 and stationary fronts by:

. Such indications of fronts are necessary whenever color printing is impossible or impracticable and is the way they usually appear in daily papers. It also will be noted that the cold fronts extend south and west from the lows and the warm fronts extend south and east from the low as indicated in Section III. Furthermore, a wave or occlusion is beginning to form in northern Oklahoma and Kansas.

Other Data

Other information included on a weather map is indicated in Figure 1-22. When possible, areas of precipitation are indicated in green. Steady precipitation is indicated in solid green and showery precipitation in hatched green. Fog areas are indicated in yellow.

4. SUMMARY

The weather map is one of the most valuable aids to flight planning available in the weather station. It is all-important in planning tactical operations. It is true that the latest weather is found on the sequence, and final flight decisions must be made from them, but it is from the weather map that one may visualize at a glance flying conditions over a large area.

(B) The Military Circuit utilizes 9891, 2, 3, 4 as identification

(C) 16th Day of the month

(D) 1430 Zone time (Greenwich) In this case Mitchel A.F.B. Hempstead N.Y. is the station, making the time of the report 0930 EST

1. TIK · STATION IDENTIFICATION symbol for Tinker AFB. Each AFB and CAA station has an identification symbol listed in CAA publications.

2. S7 · SPECIAL REPORT, identified by the letter 'S'. The '7' indicates the 7th special observation for the day.

3. M · CEILING CLASSIFIED as measured. A letter immediately preceding a numerical value for ceiling classifies the value as follows:

A - Aircraft	E - Estimated	P - Precipitation
B - Balloon	M - Measured	W - Indefinite

4. 3V · CEILING is 300 ft. variable. Ceiling is expressed in hundreds of feet. The letter 'V' indicates a variable ceiling.

5. ⊕⦶ SKY CONDITION is overcast, lower broken. Dark and thin clouds are represented by symbols (+) and (−) respectively preceding the sky condition to which they apply.

6. 1½V · VISIBILITY is 1½ statute miles variable.

7. L · WEATHER is light drizzle. Weather is reported as follows:

T - Thunderstorms	L - Drizzle	S - Snow
A - Hail	R - Rain	SW - Snow showers
AP - Small Hail	Q - Squalls	ZL - Freezing drizzle
E - Sleet	RW - Rain showers	ZR - Freezing rain

8. FK · FOG AND SMOKE. The following symbols indicate obstructions to vision:

BD - Blowing dust	D - Dust	H - Haze
BN - Blowing sand	F - Fog	K - Smoke
BS - Blowing snow	GF - Groung fog	

9. 146 · SEA LEVEL PRESSURE is 1014.6 millibars.

10. 66 · TEMPERATURE is 66° F.

11. 65 · DEW POINT is 65° F.

12. →3 · WIND is from the West at 3 knots (CAA & WB stations report mph).

13. 997 · ALTIMETER setting is 29.97 inches.

14. E7⊕CIGVRBL2T04 · Estimated 700 ft. overcast. Ceiling is variable 200 to 400 ft.

15 & 16. TERMINAL FORECAST Code Groups, included only in reports from Air Force Bases. See Terminal Forecast poster for explanation.

The U. S. Weather Bureau circuit (See Fig. 1-17) which furnishes a teletype report dealing only with civil weather observation stations is identified as follows:

CHAPTER 2 - NAVIGATION

1. GENERAL

The purpose of the navigation part of this book is to acquaint the prospective Air Force officer with some of the fundamental principles of navigation in order that he will better appreciate the problems involved when an airplane is flown from place to place. He will, thus, be better prepared to accomplish his own special assignment and thereby contribute more to the primary mission of the Air Force.

No attempt will be made to develop a practical navigator. The course in navigation is designed to be purely orientational.

Air navigation is the art of directing an airplane from one place to another and of determining its position at any time.

In its simplest form, air navigation is the guiding of an airplane by means of landmarks. The early-day flier found his way by following rivers and railroads and by watching for prominent towns and peaks much as a motorist finds his way by following the highway and by turning at the village church or the red barn.

This crude technique of navigating by landmarks was satisfactory for short daytime flights made within sight of the ground. But aircraft design progressed, production increased and traffic expanded. As air transportation grew in importance, the need arose for precise schedules to handle traffic by night as well as by day, over water as well as over land, and in foul weather as well as in fair. The old hit-or-miss method of navigation no longer was adequate; it had to be

THIS PAGE IS DECLASSIFIED IAW EO 13526

replaced by newer and more precise techniques.

In his attempt to improve the methods and instruments of air navigation, the airman logically turned to the long-established science of marine navigation. There he found much to borrow. Some of the precise equipment of the marine navigator, however, was too heavy and bulky for the airplane. Likewise, some of the marine navigator's techniques were too cumbersome and slow for use in a fast-moving airplane. Thus, it was imperative for the airman to design lighter, more compact equipment and simpler, quicker methods. Of course, some of the problems of air navigation had no close parallel in marine navigation. These problems had to be solved independently. Air navigation, therefore, progressed by the improvement of old instruments and methods and the invention of new.

A highly-organized system of government radio and lighting aids along the established airways of this country now makes possible the efficient operation of commercial airline schedules. These aids simplify the navigation problem, making it possible to navigate without a complete knowledge of the forces acting on the airplane. Consequently, on a commercial airliner the pilot and co-pilot can do their own navigation.

The navigation of military aircraft, however, is not quite so simple. These aircraft must fly where government aids may not be available. Furthermore, the pilot finds that maneuvering a bomber in formation demands his full attention. The navigator thus becomes an essential member of the crew.

Military airplanes fly several types of missions involving different navigational problems and techniques. The transport navigator is concerned with long, straightline flights, where fuel saving is a primary consideration. The bomber navigator must fly his course to avoid flak installations and enemy fighter bases. The Air-Sea Rescue navigator must make good a predetermined flight pattern in order to cover fully the area to be searched. But despite the differences in their problems, all these navigators have received the same navigational training, and all use basically the same methods. A navigator with a thorough knowledge of the basic principles of his craft can solve the special problems of any mission he may be required to fly.

The Navigator's Method

The navigator has three major problems. He must be able to determine the **position** of the airplane at any time, the **time** at which the airplane will reach any position, and the **way** to head the airplane to reach any desired destination.

The basic method used by the navigator to solve these three problems is called "dead reckoning," a term borrowed from the mariner and which means deduced reckoning. To solve each problem, the navigator must know certain facts. Thus, to find the position of an airplane by dead reckoning, he must know the **position** of the point of departure, the **direction** of flight, the **speed** of the airplane and the length of **time** it has been flying. Once these facts are known, the solution of the problem is very simple. For example, if an airplane has been flying due west from point "X" at a speed of 180 miles per hour for 20 minutes, its position obviously is 60 miles west of point "X." Finding the time an airplane will reach a given position is a variation of the same problem. The difficulty is not in solving these problems but in obtaining necessary facts as to speed and direction of flight.

The ever-present and never-predictable wind makes it difficult to determine the facts as to the airplane's speed and direction of flight. The airplane does not crawl along the earth's surface; rather, it flies through the air, which itself is moving across the earth. The navigator's instruments tell him how fast he is moving in relation to the air; but he may be flying faster or slower in relation to the earth, depending on whether he is flying with or against the wind. The wind affects not only the speed of flight but also its direction. Wind causes an airplane to drift away from the direction in which it is headed, just as a river carries a rowboat downstream as the boat crosses. The navigator's compass tells him the direction in which the airplane is headed but not the direction in which it moves over the earth.

The navigator's third problem is to de-

termine which way to head the airplane in order to reach a desired destination. This, too, is complicated by the wind. It is not enough to head the airplane in the direction of the destination, for the wind will blow it in a direction different from that in which it is headed. The wind's effect must be predicted and allowances made.

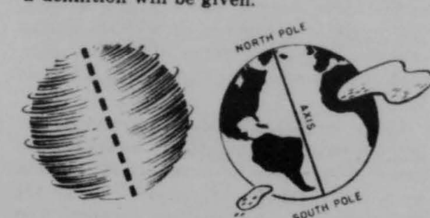
Clearly, a knowledge of the wind is very important to the navigator. The performance of his duties ordinarily demands that he keep track of the progress of the airplane and at the same time continually determine the wind.

Dead reckoning is never exact; small errors are bound to occur, and these small errors eventually add up to large errors. From time to time, therefore, the navigator must correct his dead reckoning by definitely locating his position in relation to the earth; he does this by using one of the aids to dead reckoning. Most simply, he may locate his position on a map by recognizing some landmark over which he is flying. If the ground is not visible, he may be able to find his position by the use of radio or by observation of the celestial bodies. Since the success of a mission may depend on any one of these aids, a skillful navigator must master the use of all of them as well as dead reckoning.

2. POSITION, DIRECTION, AND DISTANCE

General

Position, direction and **distance** on the surface of the earth are the very substance of navigation. Therefore, as a first step, the navigator must learn in what terms position, direction and distance are expressed. To make sure that they are all understood, a definition will be given.



The earth is a spinning ball. The imaginary line about which the earth spins is called the axis of the earth. The ends of the axis are called the north pole and the south pole.

The earth is not a perfect sphere. A sphere is a body whose surface is everywhere equidistant from a point within, called the center. Any line which passes from one side of a sphere through the center to the other side is a diameter of the sphere. Obviously, one diameter is equal to every other diameter.

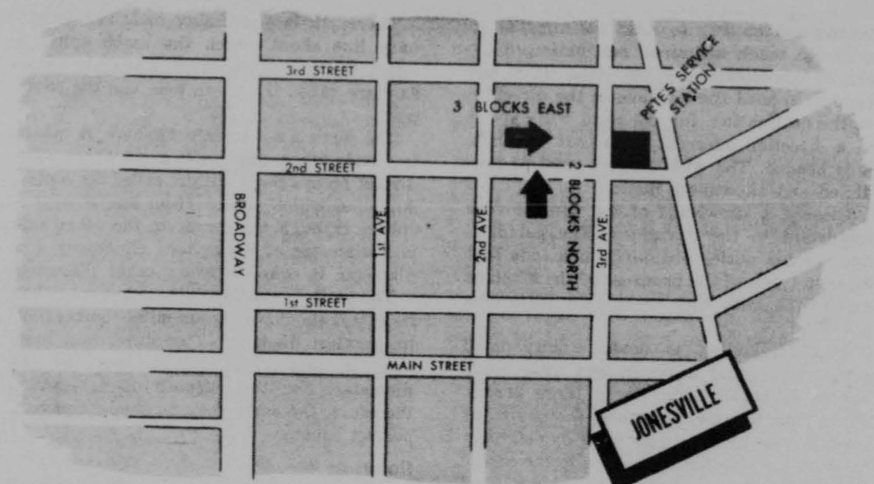
The earth is slightly flattened at the poles; its axis is about twenty-six miles shorter than its greatest diameter. This difference, however, is only about 0.3 per cent of the diameter. For the purpose of navigation, therefore, the earth may be thought of as a perfect sphere.

Position

It is necessary that some system be devised so that any **position** on the surface of the earth can be identified readily. Sometimes it may suffice to say that the airplane is ten miles east of Pittsburgh or that the destination is the Chicago Municipal Airport. That may be clear enough and simple enough. But how would the position of the airplane be designated on a trans-Atlantic flight? It would not be sufficient for the pilot to send in a position report saying that he was in the middle of the Atlantic or ten miles south of an iceberg. It is apparent that some universal method of expressing position without regard to nearby geographic features is needed.

If one were to tell a stranger the location of Pete's Service Station is Jonesville, he would say it is at the corner of Second Street and Third Avenue. This definitely tells the stranger the location, for there is only one place in all Jonesville where Second Street and Third Avenue cross. Or he may tell him that Pete's Service Station is two blocks north of Main Street and three blocks east of Broadway. This is just as definite. Quantities which give position with respect to two reference lines are called coordinates. Thus, "two blocks north" and "three blocks east" are the coordinates of Pete's Service Station relative to Main Street and Broadway.

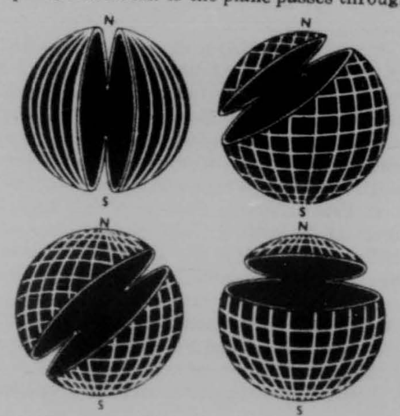
Positions on the earth may be given by



a similar system of coordinates. However, there are no natural lines on the earth to serve as reference lines. Therefore, it is necessary to use imaginary lines.

Straight lines usually are the most convenient to use. However, straight lines cannot be drawn on a curved surface. On a sphere, the most convenient reference line is a circle.

Circles on a Sphere. If a sphere is cut straight through, the cut edges are circles. Thus the intersection of a plane with a sphere is a circle. If the plane passes through the center of the sphere, dividing it in half, the circle formed is a great circle. A great circle is the largest circle which can be drawn on a given sphere. Any other circle, no matter what size, is called a small circle. The plane of a small circle of course, does not pass through the center of the sphere and hence does not divide it in half.

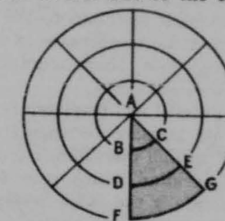


Segments of circles, or arcs, are measured in degrees, minutes, and seconds. A degree (°) is 1/360 of the circumference of a circle. Thus, if any circle is divided into 360 equal arcs, each arc is 1° in length, no matter what the size of the circle. A minute (′) is 1/60 of 1°; and a second (″) is 1/60 of 1′.

If a straight line is drawn from each end of an arc to the center of the circle, these two lines meet to form an angle at the center. This is the angle subtended at the center of the circle by the arc. Angles, like arcs, are measured in degrees, minutes, and seconds. The angle at the center of a circle always contains the same number of degrees, minutes, and seconds as the arc which subtends it.

Using degrees, minutes, and seconds of the arc, the length of any arc can be expressed; hence the distance between any two points on a circle can be expressed. This is not linear distance, but angular distance. The

angular distance between two points depends on what proportion of the circle separates them; the linear distance between them depends also on the size of the circle.



Reference Lines on the Earth. Circles make the best reference lines for designating position on a sphere. The question is where to draw the circles. A sphere is a continuous surface without beginning or end, and one point on it is just like another.

The only distinctive natural geometric line of the earth is its axis, which is different from every other diameter. Thus, the poles are distinctive points on the earth. The poles are used as the central points for one set of reference circles. The most important circle of this set is the equator.

The equator is the great circle halfway between the poles. Since the poles are 180° or half a circle apart, every point on the equator is 90° from each pole. The plane of the equator is perpendicular to the earth's axis. The equator divides the earth into a northern and a southern hemisphere just as Main Street divides Jonesville into a northern and a southern half. It serves as a reference line on the earth just as Main Street might serve as a reference line in Jonesville.

Any small circle whose plane is parallel with the plane of the equator is a parallel of latitude or simply a parallel. Each parallel is everywhere equidistant from the poles, from the equator and from every other parallel. Thus, the parallels and the equator are concentric about the polar axis.

Every point on the earth has a parallel passing through it. Only a few parallels are shown on a globe; for the globe would be solid black if they were all shown. A parallel is designated by its angular distance north or south of the equator; that is, toward the north or south pole.

A great circle passing through the poles is a meridian of longitude or simply a meridian. Meridians correspond to the north-south streets of Jonesville. But one meridian is just like another. None of them is a distinctive reference line corresponding to Broadway. Therefore, one meridian must be selected arbitrarily as a reference meridian or prime meridian. Different meridians have been used for this purpose. In English-speaking countries, and in many others, the meridian through the observatory at Greenwhich, near London, England, is used as the prime meridian.

Every point on the earth is on some meridian; as with parallels, however, only a few

THIS PAGE IS DECLASSIFIED IAW EO 13526

meridians are shown on a globe. A meridian is designated by its angular distance east or west of the Greenwich meridian, that is, right or left as one faces north.

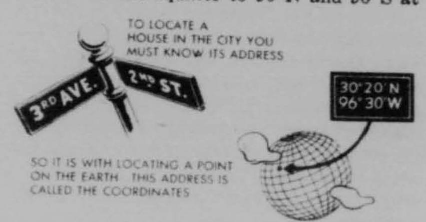
Latitude and Longitude. The parallels and meridians intersect at right angles to form a grid system comparable to the streets of Jonesville. A position in Jonesville can be designated by naming the streets which pass through it. Thus the 40°N parallel and the 75°10′W meridian together designate Philadelphia. Or a position in Jonesville can be designated by giving its coordinates relative to the two principal intersecting streets. Likewise, any point on the earth can be designated by giving its coordinates relative to the equator and the Greenwich meridian. These coordinates are called **latitude** and **longitude.**

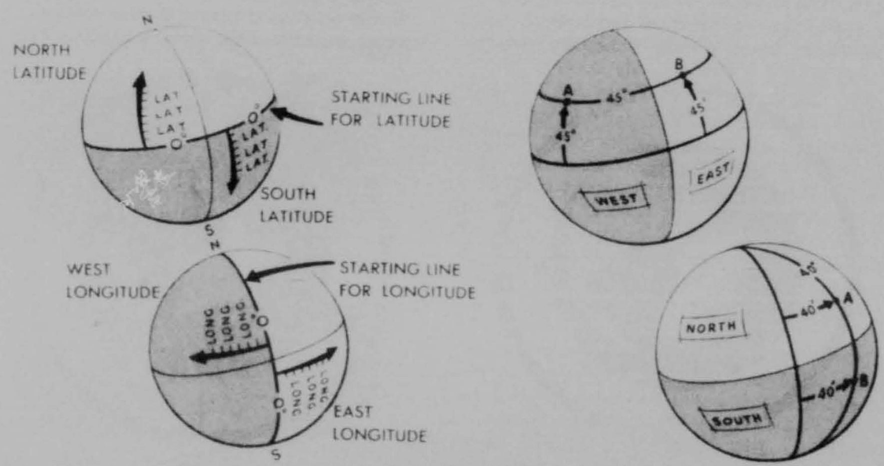
The latitude of a point is its angular distance north or south of the equator, measured in the plane of the meridian. Latitude ranges from 0° at the equator to 90°N and 90°S at the poles. **The longitude of a point is its angular distance east or west of the Greenwich meridian, measured in the plane of the equator or of a parallel.** Longitude ranges from 0° at the Greenwich meridian to 180°E and 180°W. In giving the coordinates of a point, latitude is given first, then longitude. For example, 29°03′S, 104°56′W.

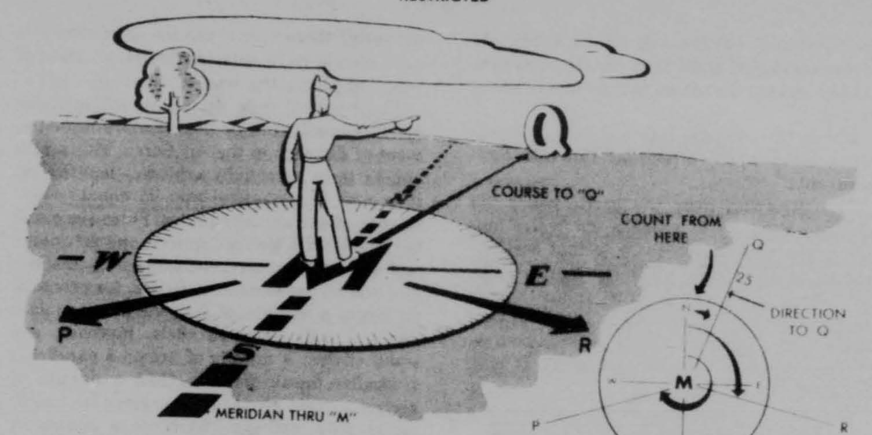
Since each parallel and meridian is named according to its angular distance from the equator or the prime meridian, naming the parallel and meridian which pass through a point is essentially the same as giving its coordinates. Note, however, that a meridian of longitude is a line; whereas longitude is an angle. Likewise, a parallel of latitude is a line; whereas latitude is an angle.

Direction

To walk across the street to the Jackson's house, a person would just glance at the house and start walking in that direction. He would seldom miss or get lost. But to fly







to Miami from Houston, he cannot use this simple method because he cannot see Miami from Houston. He would get the direction in some other way, usually from a map. Then he has the problem of keeping the airplane headed in the right direction. Obviously, direction is important in navigation. A system is needed for expressing the direction of any point from any other point.

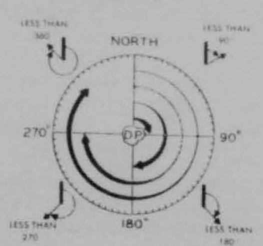
North is the direction of the north pole from any point on the earth, and south is the direction of the south pole. And as one faces north, east is to his right and west is to his left. There are only four of an indefinite number of possible directions. Some intermediate directions also have names, such as northeast, north-northeast, and northeast by north. But the number of named directions is small, and the names are cumbersome.

The system of direction used in navigation is much simpler, and it permits more exact designation of direction. Direction is expressed as an angle measured clockwise from north. At any position, one may imagine a circle whose circumference is divided into 360 equal units. If the divisions are numbered clockwise from north, they indicate true directions from the central point. The direction of north is 000° or 360°; East is 090°; south is 180°, and west is 270°.

The direction of Q and M is the angle from north clockwise to the line MQ. In other words, it is the angle between the meridian and MQ. The direction of Q is 025°. Likewise, the direction of R from M is 100°. And the direction of P from M is 260°.

A navigator must learn to think of directions as angles and practices estimating the directions of lines. Unless there is some device such as an arrowhead to show which way a line points, the line has two directions differing by 180°. Later, when he is measuring directions, he must be very careful not to make a 180° error. This is a serious mistake which is easy to make. He insures against this mistake by learning to estimate direction. Then he can check measurements by common sense. He can see at a glance that

Quadrant	*Boundaries*	*Directions*
1	North and East	000° to 090°
2	East and South	090° to 180°
3	South and West	180° to 270°
4	West and North	270° to 360°



THIS PAGE IS DECLASSIFIED IAW EO 13526

the direction of Q from M is about 025°. If it was measured as 205°, it would be apparent to him that the measurement was in error by 180°.

Divide the compass into quarters or quadrants. Note which directions fall into each quadrant:

The direction over the earth which an airplane must fly to reach a given destination is the true course (TC) to that destination. It is often simply called "course." The line which the airplane must follow across the earth or across the map to reach its destination also is called course or true course. Where necessary to avoid ambiguity, it may be called the TC line.

The direction of a line on the earth is the angle it makes with the meridians it crosses. The meridians themselves, of course, run north and south. The equator and parallels of latitude, which intersect all meridians at right angles, run east and west. Except for the equator and the meridians, every great circle intersects successive meridians at different angles. That is, the direction of the great circle changes from place to place on the earth.

It follows that any line which crosses successive meridians obliquely at the same angle cannot be a great circle. Such a line is a line of constant direction or rhumb line. The equator, the parallels and the meridians also are lines of constant direction; and loosely, they too are called "rhumb lines." However, they are complete circles; whereas a true rhumb line extended indefinitely on the earth is a spiral curve which approaches, but never reaches, the poles.

Any two points on the surface of the earth may be connected by a great circle arc. Any two points not at the same latitude or longitude also may be connected by a rhumb line.

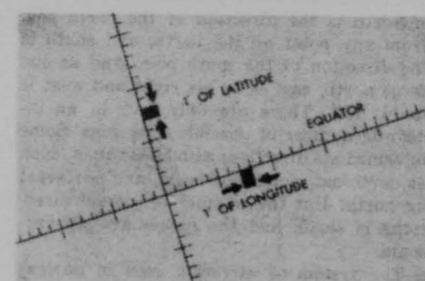
Steering by compass, it is easier to fly in a constant direction than to change direction uniformly. Therefore, the **course line** which is **easiest** to follow **is a rhumb line** and **not a great circle.** Thus, true course means rhumb-line course.

Distance

It is common knowledge that distance may be expressed in feet or miles. The ordinary mile or statute mile contains 5,280 feet. Apparently, there is no good reason why the mile should have this particular number of feet, but that's the way it is.

The nautical mile (n.m.) which contains 6,080 feet will soon be the standard measurement of distance in the Air Force. This might appear to be an equally arbitrary length; but it is not. The nautical mile is equal to one minute of arc on the equator. Since the earth is considered a perfect sphere, the meridians and the equator are considered as great circles and all the same size. Hence, for practical purposes, a minute of latitude also equals a nautical mile. The parallels, however, are small circles. A minute of arc on a parallel is a smaller linear distance than a minute of arc on a great circle; furthermore its length varies with latitude. Therefore, a minute of arc on a parallel is not a nautical mile.

There is no absolute rule that nautical miles must be used to navigate. Usually nautical miles are more convenient, and this is especially true in celestial navigation. Sometimes, however, there is a good reason for using statute miles. Just be sure not to mix the two systems of measurement; that is courting confusion. In this section nautical miles are used almost entirely.

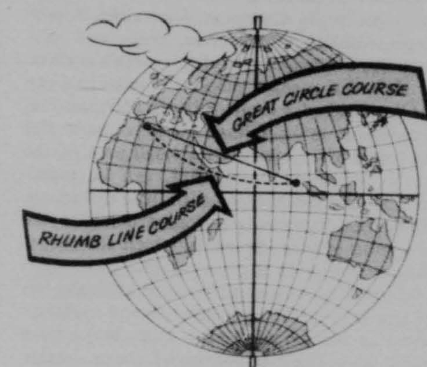


Great-circle Distance. The shortest distance between two points is a straight line. But a straight line cannot be drawn on the curved surface of the earth. The shortest distance between two points on the earth lies along the great circle passing through these points. There are two arcs of the great circle connecting these points; the shorter arc is the great-circle distance. The shorter arc of the great circle between two points is more nearly a straight line than is the arc of any

other circle which can be drawn on the earth between these points.

Through two points "A" and "B," draw two circles of different sizes. Obviously, the shorter arc of the larger circle is more nearly a straight line than the arc of the smaller circle. The larger the circle, the more nearly this arc will approach a straight line, and hence the shorter the distance along it between "A" and "B." Remember that a great circle is the largest circle which can be drawn on the earth.

Because the shortest distance between two



points is a great circle arc, one might think that an airplane should always fly the great-circle course from departure to destination. In low and middle latitudes and over short distances, however, the rhumb-line distance between two points is not much greater than the great-circle distance. The saving in distance would not repay the trouble of following a great circle. Ordinarily, the rhumb-line course will be flown and the great-circle course will be ignored.

On long flights at high latitudes, however, the rhumb-line course may be considerably longer than the great-circle course. Compromise is made by flying a series of rhumb-lines which approximates a great circle.

3. MAPS AND CHARTS

General

A map is a graphic representation of a portion of the earth's curved surface projected upon a plane surface. A map prepared especially for use in navigation is often called a chart. Formerly, when all navigation was on the sea, charts were of water areas with coastlines. Now, however, air-navigation charts show details of land areas as well as water areas. In air navigation the terms "map" and "chart" both are used.

Charts are important navigational equipment. On a chart the navigator keeps track of the airplane's position and measures the true course and distance to destination from the departure point and from other positions established en route.

Scale

Obviously, maps are much smaller than the areas which they represent. The ratio between length on a map and the true distance it represents on the earth is the scale of the map. The scale may be relatively uniform over the whole map, or it may vary greatly from one part of the map to another.

Maps are made to various scales for different purposes. If a map is to show the whole world and yet not be too large, it must be drawn to a small scale. If a map is to show much detail, it must be drawn to a large scale; then it shows a smaller area than a small-scale map of the same size. Remember: large area, small scale; small area, large scale.

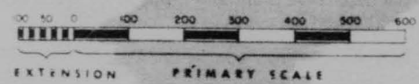
The scale of a map may be given by a simple statement, such as, "one inch equals ten miles." This of course means that any-

thing actually ten miles long is shown one inch long on the map. On aeronautical charts, the scale is indicated in one of two ways.

Representative Fraction

The scale may be given as a representative fraction, such as, 1:500,000 or 1/500,000. This means that one of any unit on the chart represents 500,000 of the same unit on the earth. For example, 1 inch on the chart represents 500,000 inches on the earth.

A representative fraction can be easily converted into a statement of miles to the inch. Thus, if the scale is 1:1,000,000, 1 inch on the chart stands for 1,000,000 inches or $\frac{1,000,000}{6080 \times 12}$ nautical miles = about 13.7 n.m. Similarly, if the scale is 1:500,000, 1 inch on the chart represents about 6.85 n.m. Thus, the larger the denominator of the representative fraction, the smaller the scale.



Graphic Scale

The scale may be shown by a graduated line. This is merely a distance as it appears on the map labeled in terms of the actual distance it represents on the earth.

The distance between parallels of latitude is a convenient graphic scale, for it is known that 1° of latitude always equals 60 n.m. Often the meridian is divided into minutes of latitude, which of course equal nautical miles.

4. MAP MAKING AND PROJECTION

General

The surface of the earth may be truly represented only on a globe. Because the globe has the same shape as the earth, directions, distances, shapes, and areas all may be shown faithfully.

For some purposes, a globe is the most useful representation of the earth's surface. For other purposes, however, a globe is inconvenient because of its shape and its bulk. To be useful in navigation, a globe must be of large scale in order to show detail. However, a large globe cannot be carried conveniently; nor would sections of a globe be easy to handle. Consequently, navigational charts are always printed on flat sheets of paper.

Distortion

A spherical surface cannot be spread out on a plane; it is said to be nondevelopable. A complete orange peel cannot be flattened without tearing, stretching, or wrinkling it. Likewise, the surface of the earth cannot be represented perfectly on a flat surface. There is bound to be distortion. **Distortion is misrepresentation of direction, shape and relative size of the features of the earth's surface.**

Note that a small piece of orange peel can be flattened with comparatively little tearing, stretching or wrinkling; for it is nearly flat to begin with. Likewise, a small area of the earth, which is nearly flat, can be represented on a flat surface with little distortion. Distortion becomes a serious problem in the mapping of large areas, in which the curvature of the earth is pronounced.

Distortion cannot be avoided entirely, but it can be controlled somewhat and systematized in the drawing of a map. Maps have many uses. If a map is drawn for a particular purpose, it can be drawn to minimize the type of distortion which is most detrimental to that purpose.

Before considering how maps are made, consider what characteristics are desirable in a map.

The Perfect Map

There are several requirements which a map should meet. These might be called the characteristics of a perfect (but impossible) map:

The scale should be constant over the whole map.

Angles should be truly shown. If this is done, shapes will be portrayed accurately, at least in small areas.

Great circles should be shown as straight lines. A great circle is the shortest distance between two points on a sphere, and a straight line is the shortest distance between two points on the map.

A rhumb line, or line of constant direction, should be shown as a straight line. This is the line which an airplane tends to follow when steered by compass.

Certain additional characteristics, though less important, also are desirable:

The coordinates of points should be easy to find from the map; and a point should be plotted easily on the map when its coordinates are known.

Maps of adjacent areas drawn, to the same scale, should be joined easily.

Each cardinal direction always should point the same way on every part of the map. Thus a north-south line on one part of the map should parallel a north-south line on any other part of the map.

The map should be simple and easily constructed.

Equal areas should be shown as equal. If the scale were constant over the whole map, areas necessarily would be shown correctly. However, areas may be shown correctly when the scale is not constant.

Since the perfect map is impossible, all these desirable characteristics cannot be combined in one map. In fact, it is obvious that certain of these characteristics are mutually exclusive. It is possible, however, to construct a map meeting one of these requirements which is especially important for the purpose of the particular map. And, it is possible to construct a map which fulfills several of these requirements, or which, by compromise, approaches the fulfillment of several of them.

Map Making

The exact coordinates of any point on the earth may be found by astronomical means. Then, with reference to control points established in this way, the location of nearby features may be found by surveying or by aerial photography. A map is made by drawing the geographic features on a framework of meridians and parallels known as a graticule. Once the graticule is drawn, features may be plotted in their correct positions with reference to the meridians and parallels.

The construction of the graticule is a very critical step in map making. The form of the graticule determines the general characteristics and appearance of the map; and, of course, its size determines the scale. Since the meridians and parallels cannot be shown on a plane surface exactly as they would appear on a sphere, there is no one correct way of constructing the graticule. In fact, there is no limit to the number of ways in which the graticule may be drawn. For example, the meridians and parallels may be shown as straight lines, as variously curved lines, or some as straight and some as curved lines; they may be spaced in various ways; and they may intersect at various angles. Actually, the graticule always is drawn in some systematic manner.

Projection

The process of constructing the graticule is called projection. Also, each type of graticule is called a projection. In actual practice, the graticule is drawn on a plane sheet of paper in accordance with certain mathematical principles which differ with the type of projection.

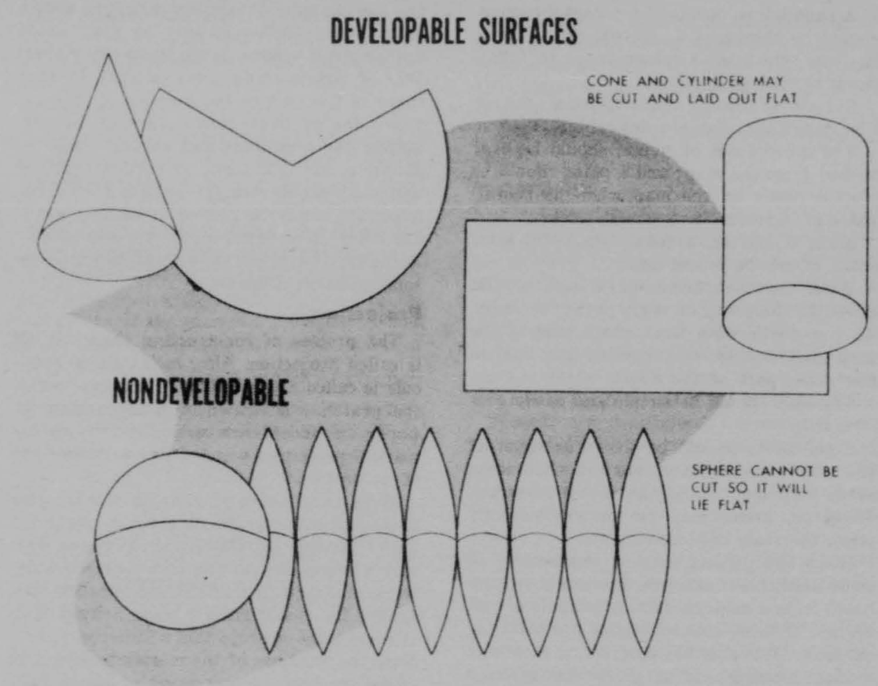
With certain map projections, it is possible to visualize the graticule actually projected onto the paper as if by a magic lantern. Picture a sphere consisting of a hollow framework of opaque meridians and parallels, say at 30° intervals. Then picture a light bulb at some point of projection within the sphere. Now the shadows of the meridians and parallels are cast on any sheet of paper held outside the sphere. In other words, the graticule is projected onto the paper.

The exact pattern of the graticule depends on the position of the point of projection and the position of the sheet of paper. Note that the surface on which the projection is made need not be plane. It can be a cone or cylinder, which can be unrolled into a plane after the projection is made. A cone or cylinder is a developable surface in contrast to the nondevelopable surface of the sphere.

If the map is visualized as actually projected onto a developable surface from some point within the sphere, one can gain an understanding of the principles of the projection. However, it is important not to forget that the projection actually is drawn on a plane sheet of paper.

Some map projections cannot be explained as projections from a point onto a developable surface. Other projections can be explained in this manner only with the as-

DEVELOPABLE SURFACES



sumption that the point of projection changes its position for different parts of the map. In any case, the term "projection" is used for the construction of the graticule.

Classes of Projections

It is not possible to classify projections so that each falls into only one category. However, there are several more or less overlapping classes which are sometimes useful.

Conformal Projections. In these projections, angles are correctly shown. Since the meridians and parallels intersect at right angles on the earth, they intersect at right angles on a conformal chart. Scale is uniform in all directions from any point; but it is not necessarily uniform at two different points on the map. Hence, shapes are correctly shown within a small area, but shapes of large areas may appear distorted.

The two projections most used in air navigation are conformal. These are the Lambert conformal conic projection and the Mercator projection. Likewise, the stereographic projection is conformal.

Perspective Projections. In perspective projections (geometrical projections), the point of projection is fixed. Usually the projection is made on a plane tangent to the earth. Examples are the gnomonic and stereographic projections.

Azimuthal Projections. In these projections, the direction of every point from the central point on the map is correctly shown. This is true of all polar projections, though it is not especially important in navigation. Sky diagrams are on an azimuthal projection.

Equal Area Projections. In these projections, equal areas are shown as equal, though at the expense of conformality. Thus, shape is not retained. This projection is of small interest in navigation.

Conventional Projections. These are certain arbitrary projections. They ordinarily are not used in navigation.

Projections used in navigation. Charts are used in navigation principally for two purposes; map reading and plotting and measuring. **Map reading is location of position by the indentification of landmarks by means of a chart. Plotting is the establishment of points and lines on a chart;** and measurement here means the measurement of direction and distance on the chart.

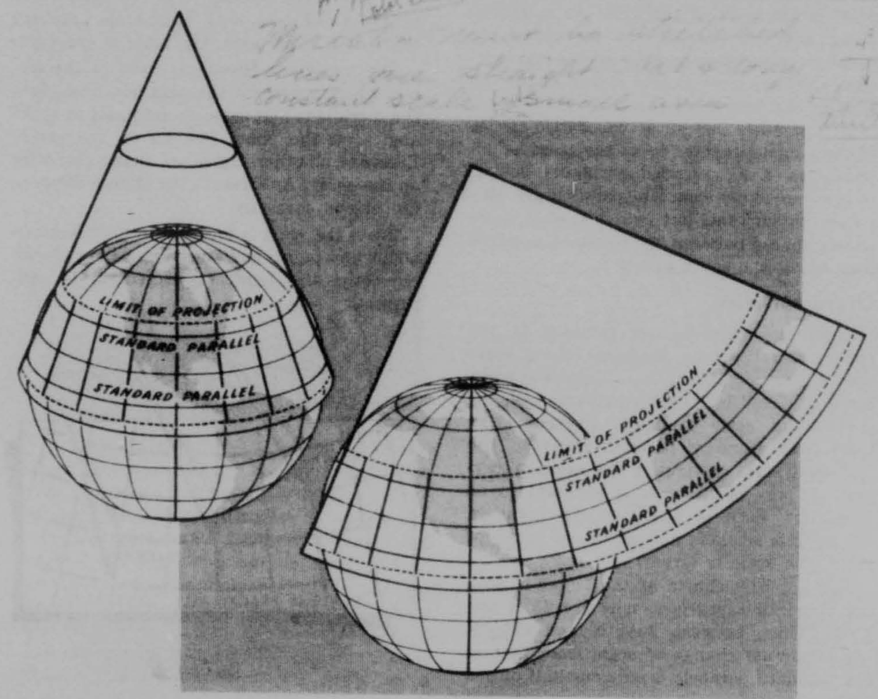
The charts most used for map reading are on the Lambert conformal conic projection. Those most used for plotting and measuring are on the Mercator projection. The stereographic projection and the gnomonic projection have special uses in navigation. Other projections also may be used; but these four are the most important.

5. LAMBERT CONFORMAL CONIC PROJECTION

General

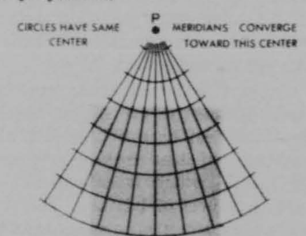
Charts of the Lambert conformal conic projection may be called simply "Lambert charts." Although other projections also bear the name of the cartographer Lambert, they are not used in navigation.

The Lambert conformal conic projection is not a true perspective projection, but it can be understood best by thinking of it as one. One may think of it as projected on the surface of a cone which intersects the earth along two parallels of latitude. The axis of the cone coincides with the axis of the earth. The apex of the cone thus lies on an extension of the earth's axis, above the north pole if the area to be mapped is in the northern hemisphere. The point of projection is on the earth's axis, but it does not remain in the



same position for all parts of the map.

The parallels along which the cone intersects the earth are called the standard parallels. Their selection depends on the latitude of the area to be mapped. They are about one-sixth of the distance from the top and bottom of the projection.



Appearance of the Graticule

The meridians appear as straight lines which converge toward a point off the top of the chart, (Northern Hemisphere). This point is the apex of the cone. As measured along any one parallel, the meridians are equally spaced; but because of the converg-ence, they are more closely spaced at the top than at the bottom of the chart.

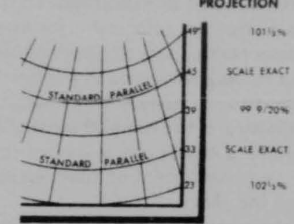
The parallels appear as concentric circles whose common center is at the point of intersection of the extended meridians, that is, at the apex of the cone. The parallels are very nearly equidistant, but are somewhat more closely spaced between the standard parallels than north and south of them.

Characteristics

Since the parallels are common to the sphere and the cone, elements along these lines are represented truly in shape and scale. Since all parallels are not equally spaced, the north-south scale gradually changes away from each standard parallel. However, the east-west scale changes in the same proportion. At any point, scale is constant in all directions. Between the standard parallels, the scale is smaller; and north and south of them, the scale is larger.

For Lambert charts of the Unted States, the standard parallels usually are 33°N and 45°N. Then, between 30½°N and 47½°N the maximum change of scale from that at the standard parallels is only one-half of one per cent. The maximum change of scale for the whole chart is 2½ per cent in southern Florida.

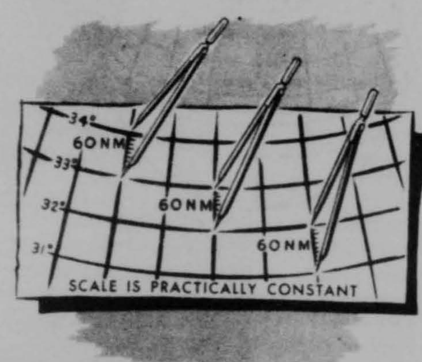
VARIATION OF SCALE ON A LAMBERT PROJECTION

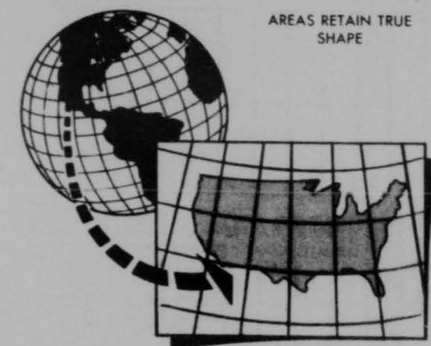


A large-scale Lambert chart of a portion of the United States is just a section of a large chart of the whole area. Thus, the standard parallels of the sectional chart are the same as those of the chart of the whole area. Though there is some change of scale over the whole area, the change is negligible over any small portion of it. Therefore, for practical purposes, on a large-scale Lambert chart of a small area, the scale is constant.

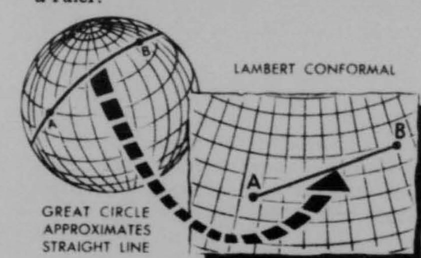
The meridians appear as radii of the circles which represent the parallels. Therefore the meridians and parallels intersect at right angles on the chart just as on the earth. Likewise, all other angles are shown correctly on the chart. As a result, the shapes of areas are shown correctly.

Since the scale is uniform in all directions about any point, and since angles are shown correctly, the Lambert projection is conformal.





Any straight line on a Lambert chart is very nearly a great circle. In the distance of 2,572 statute miles between San Francisco and New York, the great circle and the straight line connecting them on a Lambert chart are only 9½ miles apart at the mid-longitude. For shorter distances, the departure is less than proportional. Thus, for all practical purposes, if it is only a few hundred miles long, a straight line is a great circle. This is convenient since it enables the shortest line between two points to be drawn with a ruler.



A rhumb line is a curved line on a Lambert chart. The more nearly its direction is east-west, the more a rhumb line departs from a straight line. Over distances of one or two hundred miles in the latitude of the United States, a rhumb line departs little from a straight line; but over long distances the departure is large. Between San Francisco and New York, the rhumb line departs about 170 miles from the straight line. An accurate rhumb line cannot be drawn easily on a Lambert chart, but it can be approximated by a series of straight lines.

Use

Scale variation increases with the width of latitude covered by the Lambert projection. Therefore this projection is most suitable for comparatively narrow latitude bands; it is ideal for the United States. However, there is no limit to the width of longitude which may be covered with no effect on scale; the projection may extend around the earth.

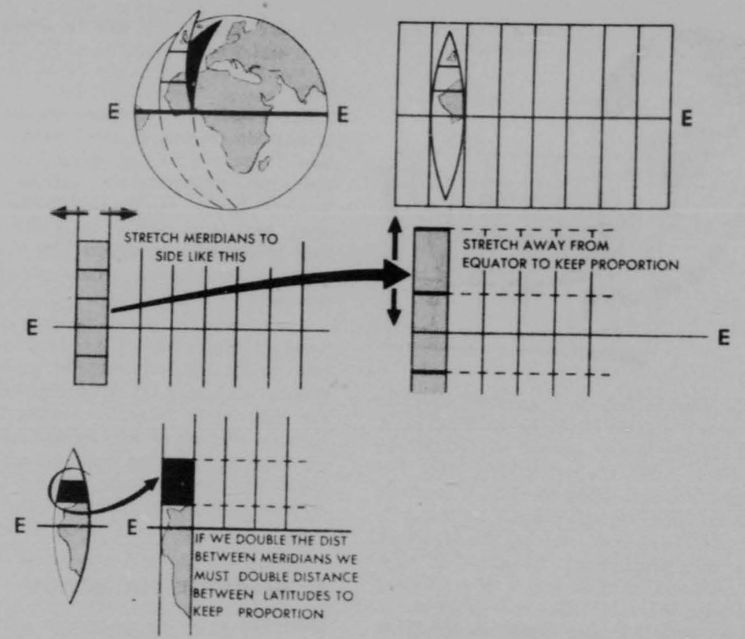
The constant scale and the conformality of Lambert charts place them among the very best navigational charts. For problems involving distances and true directions, they are superior to Mercator charts. They are suitable for use with long-distance radio-bearings. For plotting positions and measuring rhumb-line directions, they are somewhat inferior to Mercator Charts; but the difference is not necessarily great or important.

6. MERCATOR PROJECTION

General

The Mercator projection is not a true perspective projection. It best can be understood by following the steps that one might make in making a Mercator chart from a very elastic world globe. First, the surface of the globe is cut along the meridians to form a series of gores. Then the surface of the globe is peeled and laid flat on a table. It is now a good map except for its resemblance to a picket fence: the gores are connected along the equator but separated above and below, leaving blank spaces. To fill these gaps, each gore is stretched sidewards. The higher the latitude, the more the gaps are stretched to make them meet. Now a map has been made with no north-south distortion but with east-west distortion which increases with latitude. As a last step, it is necessary to make the scale uniform in a north-south and an east-west direction at every point on the map. Therefore the map is stretched in a north-south direction so that at each latitude the amount of north-south stretching is the same as the amount of east-west stretching.

THIS PAGE IS DECLASSIFIED IAW EO 13526



Appearance of the Graticule

The meridians appear as vertical straight lines which are equidistant and parallel. The parallels of latitude appear as horizontal straight lines which thus are parallel to one another and perpendicular to the meridians. Their distance apart increases with latitude.

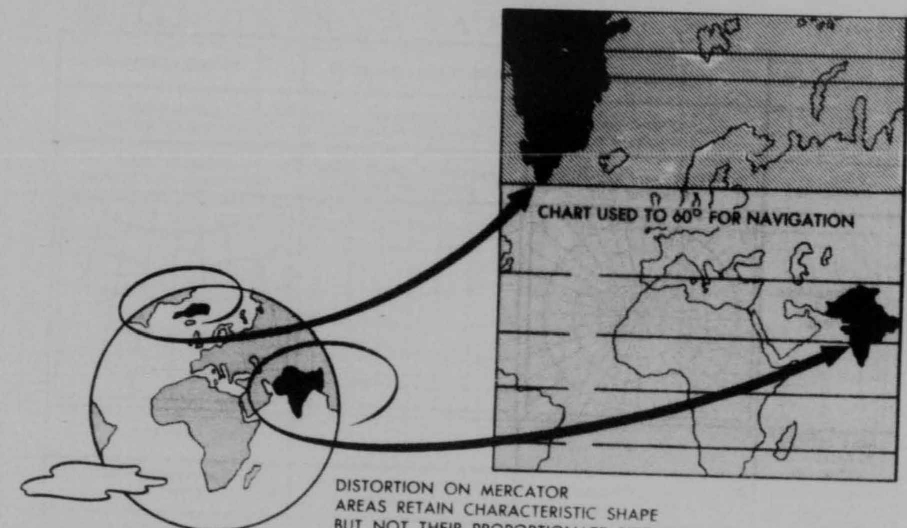
Characteristics

On the earth, meridians converge toward the poles; yet on the Mercator chart, they appear as parallel. Meridians which are 10 miles apart at the equator are only 5 miles apart at the 60° parallel; yet on the chart they appear equally far apart throughout their length. On the chart, therefore, the east-west scale is increased so that it is twice as great at the 60° parallel as it is at the equator. Consequently, the parallels must be so spaced on the chart that the north-south scale increases in the same proportion. Thus parallels, which are the same distance apart everywhere on the earth, are shown twice as far apart at 60° as at the equator. Their distance apart increases progressively with their distance from the equator. As a result, the scale at any point is constant in all directions.

The meridians and parallels are shown as intersecting at right angles on the chart just as on the earth. Likewise, all other angles are shown correctly. This means that shapes are shown correctly within small areas, though the expanding scale causes distortion of shape over large areas.

Since scale is uniform in all directions at any point, and since angles are correctly shown, the Mercator projection is conformal.

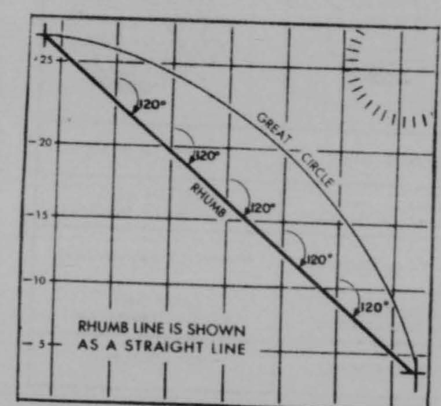
A rhumb line or line of constant direction crosses every meridian at the same angle. Since angles are correctly shown on a Mercator chart, a rhumb line is shown crossing every meridian at the same angle. Because the meridians appear as parallel lines, any line crossing them at a constant angle must be a straight line. On a Mercator chart, therefore, every line appears as a straight line, and every straight line is constant in direction. The Mercator projection is unique



DISTORTION ON MERCATOR
AREAS RETAIN CHARACTERISTIC SHAPE
BUT NOT THEIR PROPORTIONATE SIZE

among all projections in having this characteristic. Since the airplane tends to follow a rhumb line, it is a great advantage to be able to draw a rhumb line as a straight line.

The equator and the meridians are the only great circles which appear as straight lines on a Mercator chart. They, of course, are the only great circles which are also lines of constant direction. All other great circles appear as curved lines, which cannot be drawn easily.



Use

The Mercator chart is the standard navigational chart of mariners; it also has great value in air navigation. The greatest advantage of a Mercator chart is the fact that a rhumb line is a straight line. There are other advantages.

Plotting is easier on a Mercator than on any other navigational chart because the graticule is rectangular. The cardinal directions are the same on every part of the chart. Thus a north-south line is always parallel to the sides of the chart, and an east-west line is always parallel to the bottom. All Mercator charts are similar; charts of adjacent regions drawn to the same longitude scale will fit together exactly. Lastly, the chart is easily constructed.

Long-range radio bearings cannot be plotted on a Mercator chart without special corrections. In this respect Mercator charts are inferior to Lambert, polar stereographic, and gnomonic charts.

The expanding scale of the Mercator chart is a great disadvantage in navigation. This

can be overcome by using a scale which is an average for the latitude band in which the measuring is done.

The scale of a Mercator chart expands slowly in the vicinity of the equator and rapidly in polar latitudes. The Mercator projection is best suited for use within 15° or 20° of the equator. At latitudes above 70° or 80° it has little value.

7. POLAR STEREOGRAPHIC PROJECTION

General

The polar stereographic projection is a true perspective projection. It is made on a plane tangent to the earth at the pole. The point of projection is the opposite pole. Stereographic projections often are made with other points of tangency, but these are not much used in navigation.

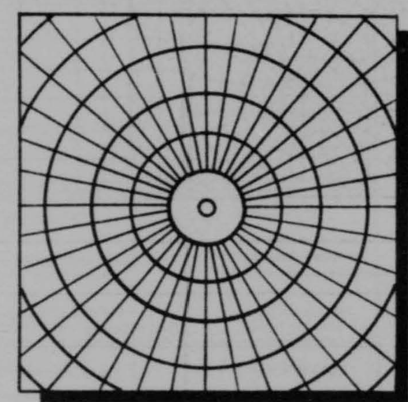
Appearance of the Graticule

The pole appears at the center of the projection. The meridians appear as straight lines radiating from the pole. The angle between any two meridians is equal to their difference of longitude. The parallels appear as circles concentric about the pole. Their distance apart increases somewhat with their distance from the pole.

Characteristics

A stereographic map may include a whole hemisphere. However, the polar stereographic charts used in navigation do not extend more than about 20° or 30° from the pole. The characteristics given here are those of a polar stereographic navigational chart; they would not apply so well to the outlying portions of a hemisphere map.

Since the interval between parallels increases slightly with their distance from the pole, the north-south scale also increases away from the pole. The east-west scale increases in the same proportion, so that at any point the scale is constant in all directions. Within the limits of the navigational chart, the scale changes little. In fact, for all practical purposes, the scale is constant.



Since the meridians appear as radii of the circles representing the parallels, the meridians and parallels intersect at 90° on the chart just as on the earth. It is also true that all other angles are correctly shown.

Because the scale is uniform in all directions about any point, and because angles are correctly shown, the polar stereographic projection is conformal. Another characteristic of the projection is that a circle on the earth always appears as a circle on the chart.

Meridians which are great circles, appear as straight lines. Hence, any great circle passing through the center of the chart appears as a straight line. Other great circles appear as slightly curved; but the closer they are to the center, the more nearly straight they appear. Within the limits of a navigational chart, for all practical purposes, a great circle is shown as a straight line.

Rhumb lines appear as curved lines.

The characteristics of a polar stereographic chart are very similar to those of a Lambert

chart. This is not surprising, for the polar stereographic projection may be thought of as the extreme case of the Lambert projection, with the cone flattened out into a plane.

Use

The polar stereographic chart is perhaps the best chart for navigation in polar regions. The Mercator chart, of course, is completely useless in these latitudes.

8. GNOMONIC PROJECTION

General

The gnomonic projection is a true perspective projection made on a plane tangent to the earth. The point of projection is at the center of the earth and therefore lies in the plane of every great circle on the earth. As a result, every great circle is projected as a straight line. This is the most important fact concerning the gnomonic projection.

Appearance of the Graticule

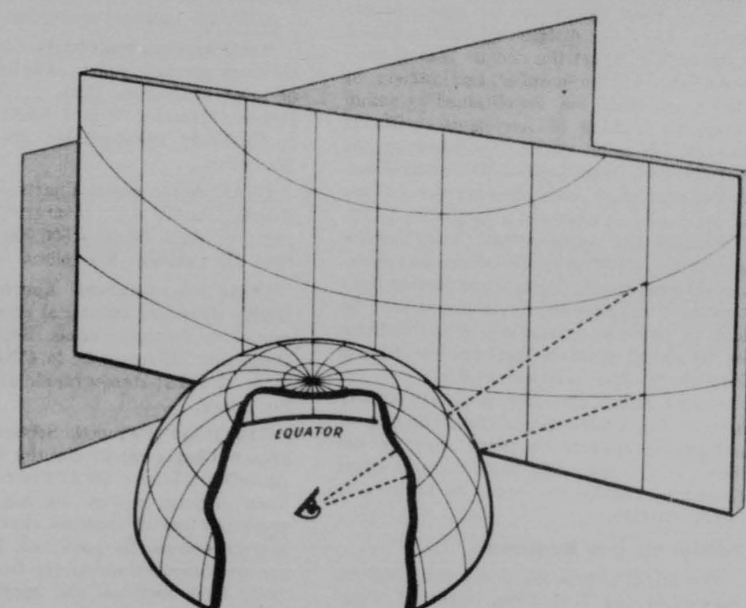
The equator and the meridians, being great circles, always appear as straight lines. The parallels, not being great circles, always appear as curved lines (ellipses or circles).

The general appearance of the graticule depends on the point of tangency. If either pole is the point of tangency, the graticule looks somewhat like that of a polar stereographic. The meridians appear as straight lines radiating from the pole at the center of the chart. The parallels appear as circles concentric about the pole; but their distance from the center increases rapidly. The equator would be infinitely far from the center.

If the point of tangency is on the equator, the meridians appear as nonequidistant, parallel straight lines. They are perpendicular to the equator, which is also a straight line. The parallels appear as unequally-spaced nonparallel curves which are bowed toward the equator at the center of the projection.

If the point of tangency is between the equator and the pole, the meridians appear as convergent straight lines. The parallels appear as unequally-spaced, nonparallel curves which are bowed toward the equator along the central meridian. The central mer-

PLANE TANGENT AT THE EQUATOR



THIS PAGE IS DECLASSIFIED IAW EO 13526

idian intersects the equator and parallels at right angles.

Characteristics and Use

The scale of a gnomonic projection increases rapidly away from the point of tangency. And it is not constant in all directions about any point except the point of tangency. Therefore distances are difficult to measure, and areas are not shown correctly. Shapes and angles also are misrepresented. Plotting of points is difficult because of the irregularity of the graticule. In short, the gnomonic chart has few merits. On a gnomonic chart, every straight line is a great circle. Therefore the shortest line between two points can be found by laying a ruler between the two points and connecting them with a line. The principal use of the gnomonic chart is in planning great-circle routes.

9. AERONAUTICAL CHARTS

General

The charts used in the Air Force are supplied by Base Operations or some similar agency. They are distributed by the USAF Aeronautical Chart Service in Washington.

An idea of the number and variety of charts published, may be obtained by examining the Catalog of Aeronautical Charts and related publications, published by the Aeronautical Chart Service. The catalog contains index maps, each showing the outlines of the published charts of a particular series.

Because the Aeronautical Chart Service constantly is publishing new charts and revising old ones, the catalog must be revised from time to time. Between revisions, it may be kept up to date by reference to the Bulletin of New and Revised Aeronautical Charts Published, which is issued weekly.

United States aeronautical charts usually are revised at least once a year. The date of publication appears on every chart in the lower left corner. The date on any chart should be checked in order to be sure it is not obsolete.

Sectionals and Regionals

For several years the Coast and Geodetic Survey of the U.S. Department of Commerce has published aeronautical charts of the United States. **Those on a scale of 1:500,000 are known as Sectional Charts. Those on a scale of 1:1,000,000 were known as Regional Charts.** These regional charts are no longer published; their place has been taken by the World Aeronautical Charts on the same scale.

Since no other suitable terms existed, the terms "sectional" and "regional" were extended to include similar charts published by other agencies. Thus, a sectional chart or a sectional is an aeronautical chart on a scale of 1:500,000 designed especially for map reading. Similarly, a regional chart or a regional is an aeronautical chart on a scale of 1:1,000,000 designed especially for map reading.

Charts of the World

The following list gives the most important aeronautical charts which are available for all parts of the world. A few other series are listed in the Catalog of Aeronautical Charts and related publications.

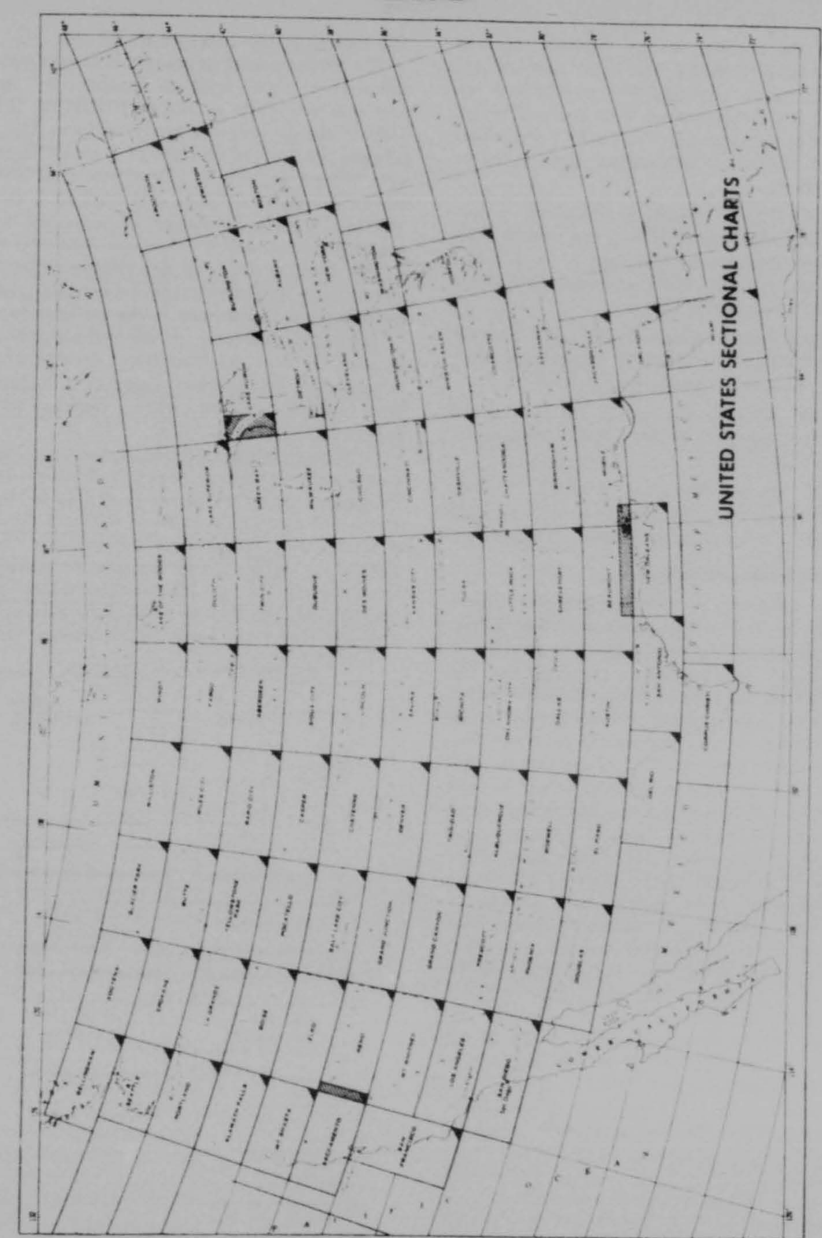
U.S. Planning Chart. One for the United States (from a complete world series). Scale 1:5,000,000. Lambert projection. Five colors.

World Aeronautical Charts. Complete world coverage planned; charts have been published of most land areas. Scale 1:1,000,000. Projection: Mercator 0° to 4°N&S; Lambert 4° to 72°N&S; stereographic above 72°N&S. Six colors.

USAF Aeronautical Charts. (USAF Sectionals). Partial world coverage; thus far only parts of Asia. Scale 1:500,000. Projection: thus far Lambert. Six colors.

USAF Aeronautical Approach Charts. Highly developed industrial centers and congested or strategic areas. Scale 1:250,000. Projection: Mercator 0° to 4°N&S; Lambert 4° to 72°N&S; stereographic above 72°N&S. Six colors.

The USAF Regional, Sectional, and Approach Charts constitute the USAF World Aeronautical Chart (WAC) or regional series. Each regional covers the same area as 4 sectionals and 16 approach charts, though all are not necessarily published. The regionals are numbered consecutively from 1 to about 1800. Each sectional and approach chart is



THIS PAGE IS DECLASSIFIED IAW EO 13526

given the number of the regional, part of whose area it shows. The sectionals and approach charts covering the area of one regional are distinguished from one another as shown in a diagram. On the back of each chart is a world map which serves as an index to the series.

USAF Flight Charts. Strips showing certain important air routes. Scale mostly 1:1,000,000. Projection: Mercator 0° to 4°N&S; Lambert 4° to 72° N&S; stereographic above 72°N&S. Six colors (average).

USAF Plotting Charts. 70°N to 70°S. Scale 1:3,000,000 at 37°N or S. Projection: Mercator. One color, graticule only.

USAF Plotting Charts. 17 for the United States. Scale 1:1,000,000 Mercator projection. Five colors.

U.S. Radio Direction Finding Charts. (RDF Charts). 6 for the United States. Scale 1:2,000,000. Lambert projection. Seven colors.

Chart Interpretation

An aeronautical chart is a diagram of part of the earth's surface. As a diagram, it does not picture all details; rather, it emphasizes particular features which are useful to the airman. It represents those features which have the most distinctive apearance when seen from the air. For emphasis, many features are shown out of all proportion to their true size, though centered in their correct positions. For example, the line representing a road on a regional chart may appear to be a quarter of a mile wide if measured in the scale of the chart. Radio stations are shown prominently, even though they are inconspicuous from the air. Moreover, many lines—such as meridians and parallels, isogonics, airways, and contours—take up space on the chart even though they are quite invisible from the air. Because of this necessary emphasis of important features, there is not room on the chart for all details visible from the air, especially in congested areas.

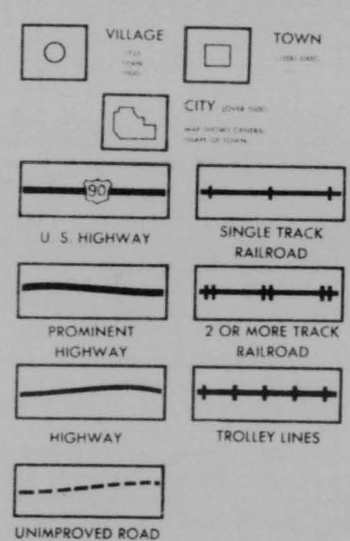
Since a chart is a diagram, it consists of symbols which do not necessarily resemble the shape or appearance of the objects they represent. Skill in map reading will depend upon the ability to understand and interpret these symbols. One must learn to visualize the terrain as one looks at the chart.

The symbols used on one set of charts may differ from those used on another; but on any one set, such as the sectionals of the United States, they are fairly uniform. Usually on the margin or back of a chart there is a legend or key to the symbols. If one learns to read sectionals and regionals, one will find it easy to change, if necessary, to another type of chart.

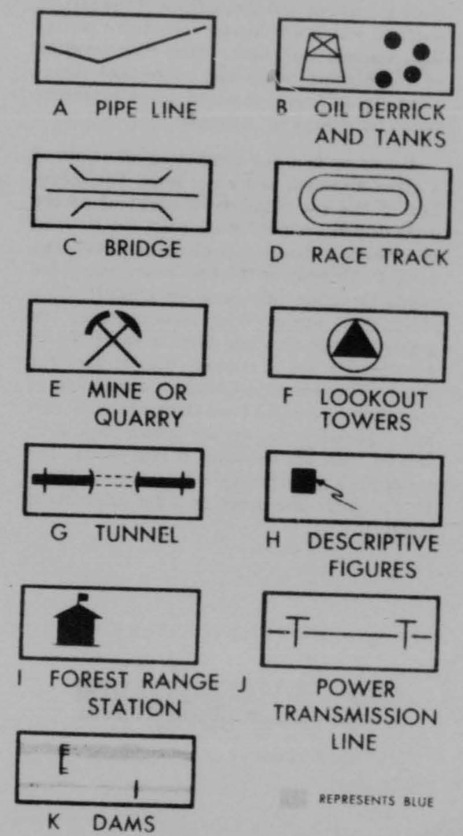
The symbols used on aeronautical charts fall roughly into two classes: **topographic and aeronautical. Topography is the configuration of the earth's surface,** including the position of such features as cities, lakes, forests, and mountains. Topographic features fall into four classes: **culture, water, forests, and relief.**

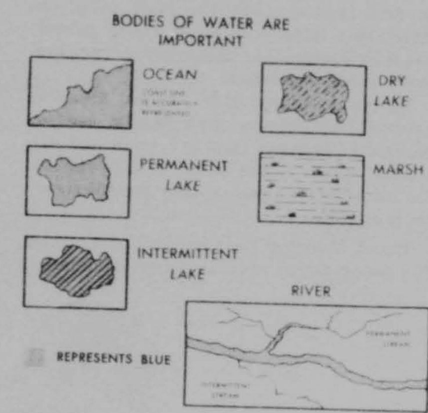
Cultural symbols represent man-made features such as towns, roads, and railroads. Cities and towns are shown according to size by several symbols. A circle or square denotes a small town, but it does not indicate the town's shape. The town can be recognized from the air only by its position relative to nearby features, such as roads, railroads, and streams. One must learn by experience just

CULTURAL (MAN-MADE) FEATURES



MISCELLANEOUS CULTURAL FEATURES





how big a town looks from the air when it is shown by a circle on the chart, and how big when shown by a square. A city, on the other hand, is represented more nearly in its true shape, and to scale.

Roads and railroads usually are conspicuous from the air. Railroads are particularly useful to the navigator since all railroads are shown on the aeronautical chart. On regional charts, comparatively few roads are shown; and even on the more detailed sectional charts many conspicuous roads are omitted, especially in congested areas. In addition, railroads usually are more permanent roads and are more likely to be shown accurately. It is sometimes difficult to distinguish between roads and railroads when seen from high altitudes. Remember that railroads do not have sharp turns. The chart may or may not show bridges, but one usually can expect to see a bridge where a road or railroad is shown to cross a stream.

Many cultural features, such as race tracks, oil fields, tank farms, and ranger stations, are shown by special symbols. There are no standard symbols for certain other conspicu-

THIS PAGE IS DECLASSIFIED IAW EO 13526

ous features, such as smoke stacks, water towers, monuments, and prominent buildings. These often are indicated by brief descriptive notes, each with an arow and perhaps a dot showing the location.

Water and Forest Symbols. Bodies of water are valuable to the navigator because they are relatively permanent; they are seen easily by day and often by night. Coastlines may be shown accurately, even though inland areas are little explored and poorly mapped. Conventionally, water is shown in blue; but this does not mean that it looks blue from the air. In arid regions, even the most important rivers may have little water above ground; but their courses may be marked by comparatively dense vegetation.

European charts show forest areas in green. These forests often can be used as landmarks because they are small and distinctive in shape and do not change rapidly. In this country, however, they are not shown on the charts.

Relief. Mountains are important to airmen for two reasons: they are good landmarks; and they are hazards to flying. Consequently, aeronautical charts make some attempt to show elevations and inequalities of the earth's surface, which are known collectively as relief. Aeronautical charts often give elevation of the highest peaks and other spot elevations. In addition, most of them represent relief by means of contours.

A contour is a line connecting all points of a given elevation above sea level. The shoreline of the sea might be thought of as the 0-ft. contour, since every point on it is at an elevation of zero feet above sea level. The 1,000-ft. contour is the line where the shore would be if the tide came up 1,000 ft. On a steep slope contours are close together; on a gentle slope they are farther apart. To an experienced eye, a contour map is just the same as a relief map, and it is possible to visualize the terrain from them. On sectionals and regionals, contours are brown lines, each labeled with the elevation it represents. The lower ones are drawn for intervals of 1,000-ft. elevation; the upper ones for intervals of 2,000 ft.

The relief shown by contours is further emphasized on sectional and regional charts by a gradient system of coloring. The area between sea level and the 1,000-ft. contours is dark green; that between the 1,000-ft. and 2,000-ft. contours is light green. The areas between successive higher contours are in different shades of brown, from light to dark. The darker-colored mountain peaks stand out conspicuously, even to someone who is not experienced at reading contours. Other series of aeronautical charts have different color schemes, and still others have only the contours.

On charts of poorly known areas, mountains may be indicated by hachures or shading lines, with the elevations of peaks given as accurately as they are known. Hachures may be used on contour charts to show prominent hills, or buttes too small to show up otherwise because of the large contour interval.

Aeronautical Symbols. Aeronautical information is printed in red or purple on sectional and regional charts. Classes of airports are distinguished by different symbols, and the elevation of each airport is given. Light beacons are shown with their code signals. Also shown are the locations of radio stations, with call letters and frequency, and the position of each radio beam. Airways, danger areas, and isogonic lines are clearly marked.

10. BASIC NAVIGATION PROCEDURE AND INSTRUMENTS

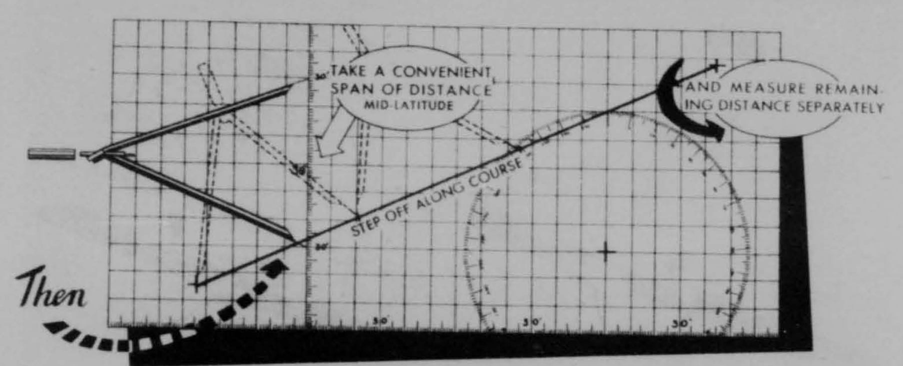
Plotting and Measuring

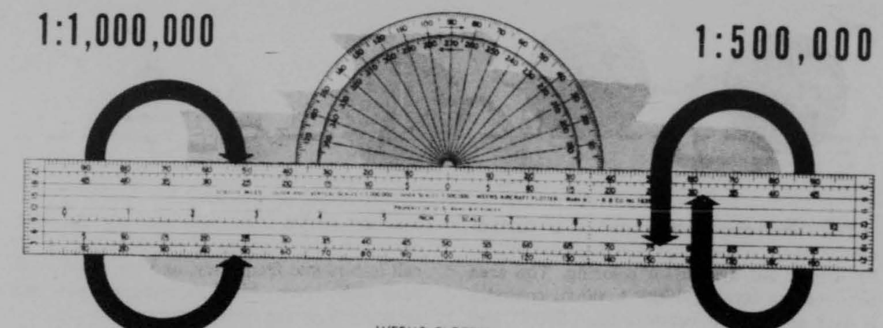
General. Plotting and measuring are basic operations in navigation. **Plotting is the establishment of points and lines on a chart with reference to the meridians and parallels.** Measurement here means the measurement of direction and distance on a chart.

Pencil, eraser, dividers, and plotter are used in plotting and measuring. Sometimes a long ruler and a triangle are found to be useful. A navigator must learn to use these instruments automatically.

Measurement of Distance. The distance between two points on a chart is usually measured by use of dividers. However, a ruler, string, or some other divider will do just as well.

It is important to remember when measur-





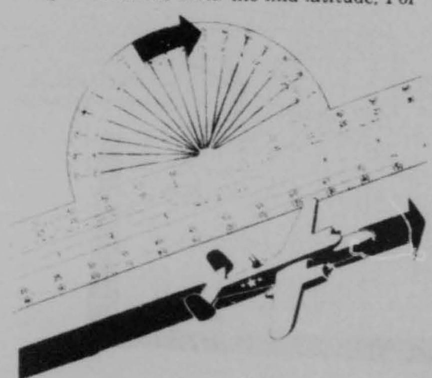
WEEMS PLOTTER

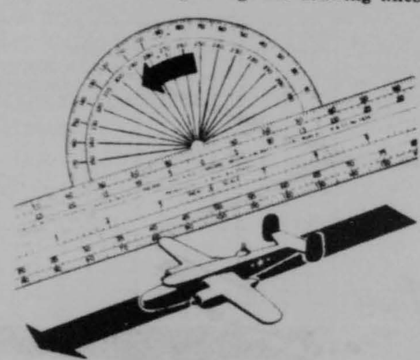
ing distance that distance scales vary with each type of projection. The distance scale on a Lambert conformal projection is constant and should give very little difficulty. But the distance scale varies with latitude on the Mercator projection, so it is necessary to use a section of the graduated meridian whose average scale is the same as the average scale over the distance to be measured. This is a section of the meridian whose mid-latitude is the same as the mid-latitude of the two points between which the distance is being measured. This scale is called the mid-latitude scale. The mid-latitude scale is not exactly equal to the average scale, but it is close enough for practical purposes.

If the total distance can be spanned with the dividers, then merely measure the distance on the graduated meridian by placing the points of the dividers on the meridian at equal distances from the mid-latitude. For a longer distance, set the dividers at some convenient distance such as 100′(100 n.m.), again by placing the points at equal distances from the mid-latitude. Step off the distance, counting the steps. After the last step, reset the dividers at the remaining shorter distance, and read this distance from the graduated meridian at mid-latitude.

The mid-latitude scale is accurate enough if the course does not cover more than about 5° of latitude. If the course does not extend over more than 5° of latitude, divide it into legs and measure the length of each leg with its own mid-latitude scale.

Plotter. The plotter is an instrument for drawing and measuring courses and measuring distances on aeronautical charts. It is made of transparent plastic with lines and scale printed in black. The rectangular part of the plotter has a straight edge for drawing lines





and has scales for measuring distances. The semicircular part of the plotter has two circular scales for measuring directions.

The circular scales are calibrated in degrees. The outer scale, reading from 0° to 180°, is for directions in the first and second quadrants. Since these directions are to the right on the chart, the outer scale has an arrow pointing to the right. The inner scale, reading from 180° to 360°, is for directions in the third and fourth quadrants. Since these directions are to the left, this scale has an arrow pointing to the left. The center of curvature of these scales is marked by a small hole.

The straight edge of the plotter is placed parallel to a line on the chart, with the center hole over a meridian, and the direction of the line is read on the circular scales over the same meridian. The line has two directions 180° apart, one of which is given by each scale. But it must be remembered that a TC has only one direction. Hence, only one scale is read. The arrows on the plotter are an aid in remembering which scale is used. However, each reading should be checked by common sense.

To measure TC, the center hole of the plotter is placed on a meridian while the straight edge of the plotter is parallel with the TC line. This requires a little juggling unless dividers or a ruler is used. If a ruler is laid along the TC line and the plotter is moved against it, the straight edge of the plotter will remain parallel with the TC line while the hole is being centered over the meridian.

The Measurement of True Course. The true course is usually measured by a plotter. However, the compass rose that appears on most charts, or a protractor can be used.

It is important to remember that the meridians are shown differently on different charts. The Mercator projection presents little difficulty in measuring TC since any meridian that is chosen as the north reference line will give the same TC, since all the meridians are parallel. But on the Lambert conformal projection, the meridians converge toward the poles. Therefore, each meridian along a course, when used as the north reference line, will give a different TC. The reason for this is that the line represents a great circle, and we are interested in a rhumb line. The mid-meridian along the course must be chosen as the north reference line, since this will approximate the rhumb-line course.

Preparing a Blank Mercator Chart. Sometimes it is necessary or convenient to draw the TC on a blank Mercator chart. The expanding latitude scale limits the Mercator

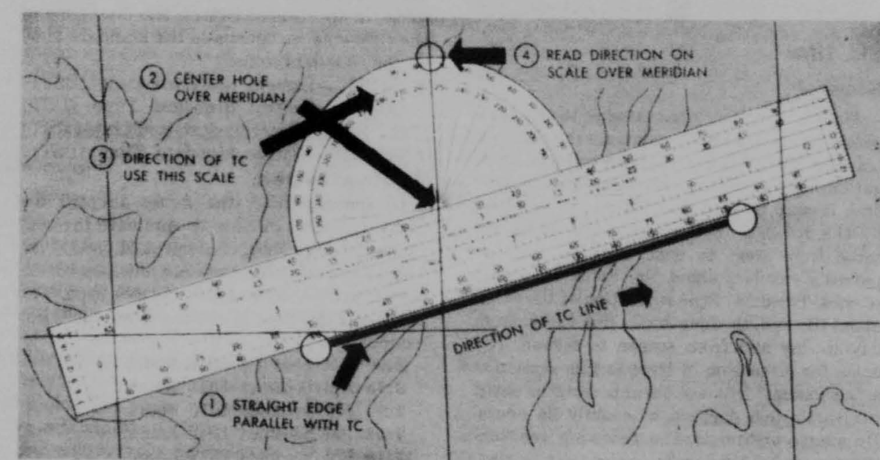


chart to use in those latitudes for which it is constructed. However, a given chart may be used either in north or in south latitude. For north latitudes, turn the chart so that latitude increases from bottom to top; and for south latitudes, turn it so that latitude increases from top to bottom.

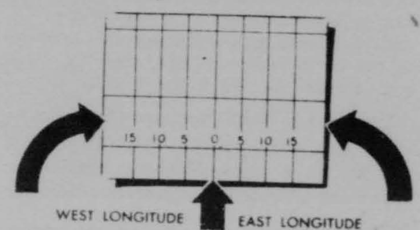
A blank Mercator chart may be used for any longitude, east or west. To prepare the chart, meridians are numbered according to the longitudes in which the flight is to be made. For flights in east longitude, the numbers must increase from left to right; and for west longitude, they must increase from right to left. The numbering must be checked to be sure that the numbers increase in the correct direction and that a number has not been skipped or one number written twice.

Use Care in Numbering Meridians



11. TIME

General

Time is of primary importance to the navigator. By its use he can calculate the distance traveled along his course, or in celestial navigation he can calculate his longitude. In general, it may be said that time is determined by the rotation of the earth. The earth rotates from west to east and the sun apparently revolves about the earth from east to west. Because of the revolution of the earth about the sun, the length of a day varies from day to day and from season to season. The basis for discussion of time in this section is a **"mean sun,"** which apparently rotates about the earth, 360 degrees, in exactly 24 hours. By simple arithmetic the following relationships may be developed:

In one hour, the sun travels 15° of longitude.

In four minutes, the sun travels 1° of longitude.

In one minute the sun travels 15′ of longitude.

It is not difficult to reason that time differs at every meridian on the earth's surface. When the sun is over the meridian of New York City, it is noon at New York City. At Boston, it is past noon, and at Washington, D.C., it is before noon. The time of places east of us is later, while the time of places to the west of us must be earlier.

Much confusion would result if each place on the earth kept its own time. For convenience the world has been divided into 24 time zones of approximately 15° longitude in width. Each time zone carries the time of the central meridian in that zone.

Kinds of Time

Mean or Civil Time is based on the travel of the mean sun about the earth. At the same instant, points of different longitude never have the same civil time.

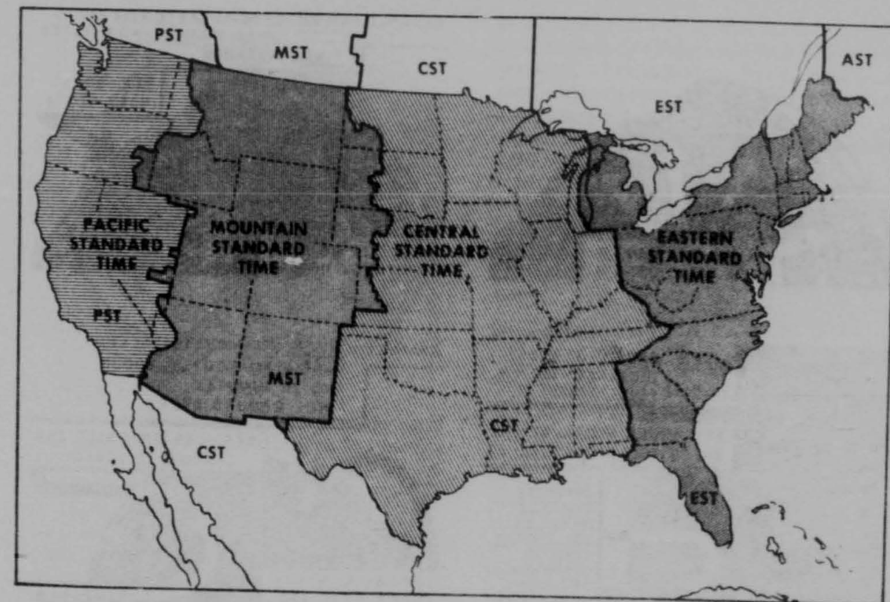
Standard or Zone Time is the time kept by watches. It is based on the civil time of a selected meridian within the time zone. Standard time zones are not all exactly 15° longitude in width. The boundaries of standard time zones are bent so they will not pass through principal cities and railway junctions. In the United States, the civil time of the following meridians is the standard time of the standard zones:

(1) 75°—Eastern Standard Time (EST)
(2) 90°—Central Standard Time (CST)
(3) 105°—Mountain Standard Time (MST)
(4) 120°—Pacific Standard Time (PST)

24-Hour System

During the War, the Army adopted the 24-hour system of time to eliminate the confusion in the abbreviations A.M. and P.M. The values of A.M. time are unchanged except that four figures are always used. The value of P.M. time is increased by 1200. For example:

8:00 AM becomes 0800 hours
3:15 AM becomes 0315 hours
1:15 PM becomes 1315 hours
7:42 PM becomes 1942 hours
11:19 PM becomes 2319 hours



Hack Watch

A navigator needs an accurate watch which has a synchronized second hand. For most of his purposes he needs to know the time accurately to the half minute, but in celestial navigation he should know the time within two or three seconds. The Air Force has developed a watch especially for this purpose (type A-11).

12. TIME, SPEED AND DISTANCE

General

The most important and fundamental problems of navigation are those involving the familiar formula of time, speed and distance. Distance in navigation is expressed in nautical miles or statute miles. The units of time used in navigation are the familiar hours, minutes, and seconds. Speed is rate of motion, or the distance traveled per unit time. Thus, it is a ratio between distance flown and time of flight. The units of speed used in navigation are statute miles per hour, which are called simply miles per hour (mph) and nautical miles per hour, which are called knots (K). Knots mean nautical miles per hour.

So long as the speed of an airplane remains the same, the distance flown increases in the same ratio as the time. Given the ratio (speed), the distance flown in a certain time or the time to fly a certain distance can be found. Or, given the distance and time, the ratio (speed) can be found. The proportion can be transformed into three formulas:

$$\text{Distance} = \text{Speed} \times \text{Time}$$

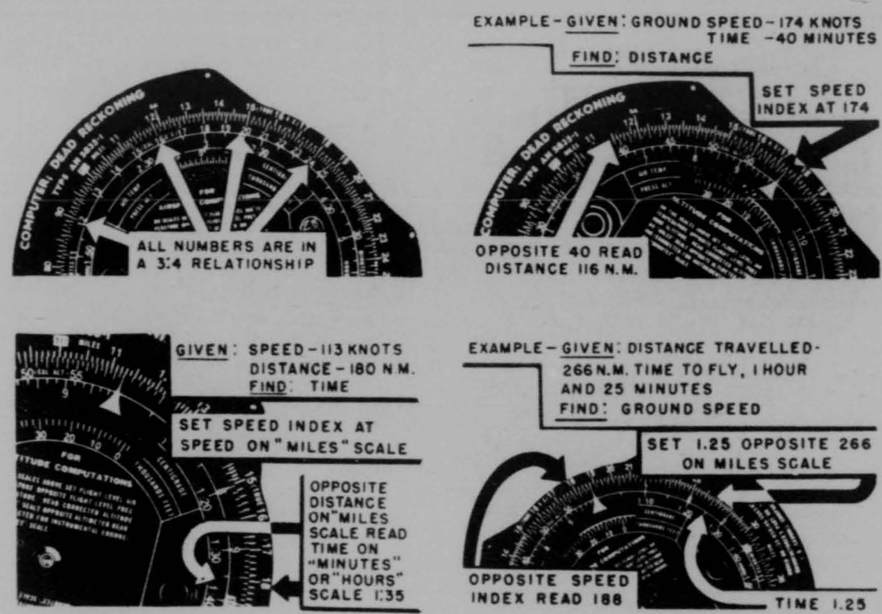
$$\text{Time} = \frac{\text{Speed}}{\text{Distance}}$$

$$\text{Speed} = \frac{\text{Distance}}{\text{Time}}$$

In using these formulas, remember that units must be consistent throughout. Thus if speed is in miles per hour, time must be in hours, not minutes. And if distance is in nautical miles, speed must be in knots, not in miles per hour.

The E-6B Computer

The Air Force has developed a special computer to solve air navigation problems called the E-6B Computer. It is affectionately known as the "wife" of the navigator.



Simple Proportion. The slide-rule face of the E-6B is so constructed that any relationship between two numbers, one on the stationary scale and one on the movable scale, will hold true for all other numbers on the two scales. If the two 10's are placed opposite each other, all other numbers will be identical around the whole circle. If 20 on the inner scale is placed opposite 10 on the outer scale, all numbers on the inner scale will be double those on the outer scale. If 12 on the outer scale is placed opposite 16 on the inner scale, all numbers will be in a three-to-four relationship. This feature of the slide rule permits one to supply the fourth term of any mathematical problem in proportion. The simplest and most useful application of this feature of the computer is in the solution of time-speed-distance problems.

13. THE MAGNETIC COMPASS

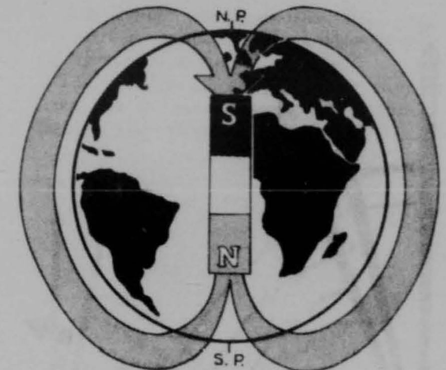
General

Orientation to direction comes almost automatically on the ground for most people because they are always near familiar landmarks. But the airman would become hopelessly lost in a short time in the air without some mechanical means of orientation as to direction. This mechanical means of orientation to direction is provided by the magnetic compass, the gyro indicator, the astrocompass, and the radio compass. Of these, only the magnetic compass is north-seeking.

Earth's Magnetism and the Compass

Since a freely suspended magnet everywhere on the earth always tends to assume a certain direction relative to the earth, it is clear that the earth itself acts as a magnet. The magnetic poles of the earth do not coincide with the geographic poles. The north magnetic pole is on the Bothia Peninsula, northwest of Hudson Bay, at about 71°N, 96°W; and the south magnetic pole is in Antarctica at about 73°S, 156°E.

If the whole earth were a magnet, one would expect a tremendous force of attraction and repulsion to occur at the so-called magnetic poles of the earth. Actually, attrac-



EARTH'S MAGNETIC FIELD

tion and repulsion at these poles is somewhat less than at some other points on the earth's surface. It is as if the earth's magnetic field is due to a short stubby magnet at the center of the earth.

A magnetized needle, free to rotate on a horizontal plane, is a magnetic compass in its simplest form. If the north-seeking pole is differentiated from the south-seeking pole, say by blue paint, the needle will serve as a crude direction finder. From most points on the earth, the needle will point in the general direction of the north magnetic pole; but it doesn't necessarily point directly toward it. Actually, the needle indicates the direction of the earth's magnetic field. Since the north and south magnetic poles are not directly opposite, it is impossible at most places on the earth for one end of the needle to point to one magnetic pole while the other end points to the other.

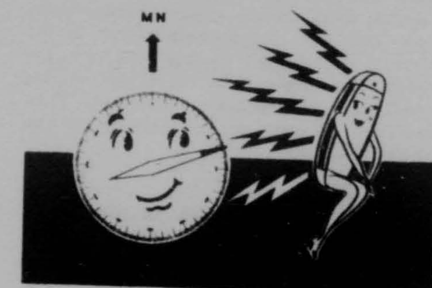
Variation

When a compass needle is influenced only by the earth's magnetic field, the direction in which it points is called the **magnetic north.** In contradistinction, the direction of the north geographic pole may be called **true north,** though usually it is called simply north. Just as true directions are measured from true north, so magnetic directions may be measured from magnetic north. **The angle between magnetic north and true north is variation.** Thus variation is the angle between the meridian and the needle of a compass influenced only by the earth's magnetism. Variation differs at different points on the earth. If the needle points to true north, then magnetic north and true north coincide; and variation is zero. If the needle points east of north, variation is east; and if it points west of north, variation is west.

In the area about either magnetic pole, variation ranges through a complete circle. Thus, north of the north magnetic pole and south of the south magnetic pole there are places where the variation is a maximum of 180°.

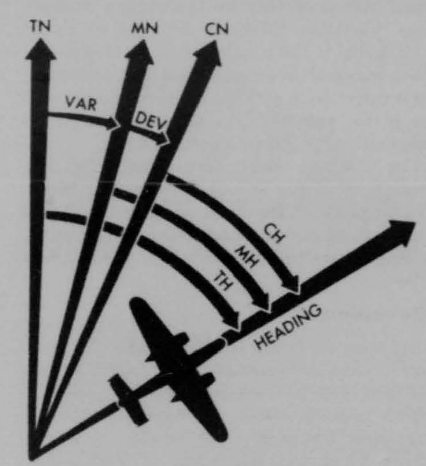
Deviation

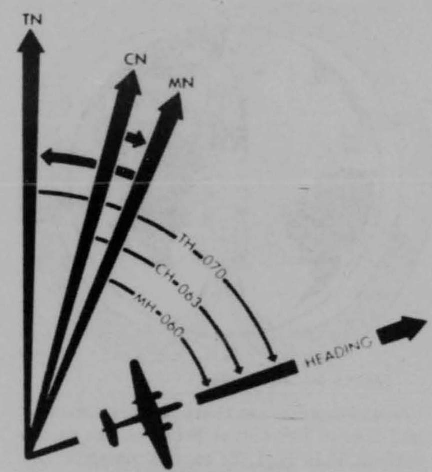
A compass needle is affected by other magnetic fields besides that of the earth. A piece of iron close to the needle tends to deflect it from magnetic north. A magnetic field is set up about a wire in which an electric current flows. Thus electrical equipment near a compass also can deflect the needle. Since an airplane has both iron and electrical equipment, the needle of an aircraft compass often is deflected from magnetic north.



The direction in which a compass needle points is called **compass north.** Compass directions may be expressed relative to compass north just as true directions are expressed relative to true north and magnetic directions are expressed relative to magnetic north.

The angle between magnetic north and compass north is deviation. Thus deviation is the angle between the compass needle and the direction the needle would point if it were affected by no magnetic influences other than that of the earth. If the needle is deflected to the east of magnetic north, devia-





tion is east; if to the west, deviation is west.

If an airplane changes heading, the compass needle continues to point in about the same direction while the airplane turns with relation to it. As the airplane turns, therefore, iron and electrical equipment in the airplane change their position relative to the needle. Hence their influence on the compass needle changes and deviation changes. Thus deviation depends on the heading of the airplane.

Heading

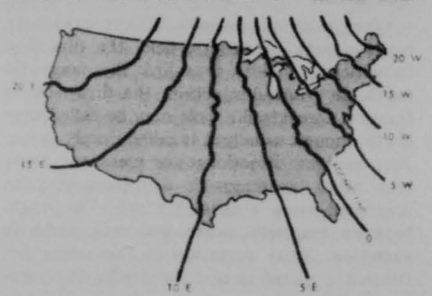
The direction in which an airplane is pointed is its heading. This direction may be expressed with relation to true north, magnetic north, or compass north. Heading measured with relation to true north is **true heading (TH).** Thus TH is the angle measured from true north clockwise to the forward end of the airplane's longitudinal axis. Likewise, heading measured with relation to magnetic north is **magnetic heading (MH)**. And heading measured relative to compass north is **compass heading (CH)**.

The compass rose of magnetic directions is turned with respect to the compass rose of true directions by the amount of variation. Thus TH always differs from MH by the amount of variation. If variation is east, TH is greater; if variation is west, it is less. Likewise, MH always differs from CH by the amount of deviation. If deviation is east, MH is greater; if deviation is west, MH is less.

It must be remembered that heading is the same direction with relation to the earth, whether it is expressed as TH, MH or CH.

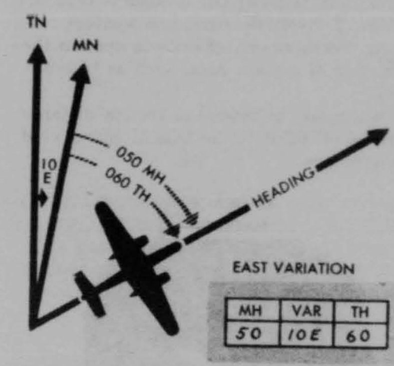
Finding Variation and Deviation

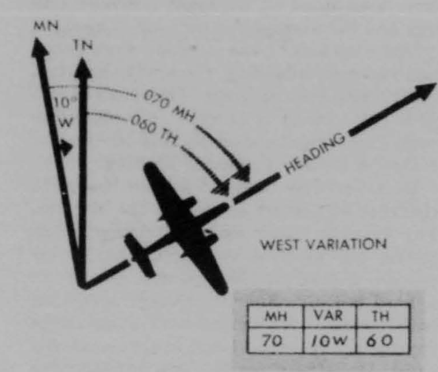
The variation for different points on the earth is fairly well-known. Variation is shown on aeronautical charts by means of lines connecting points of equal variation. Such a line is an **isogonic line.** The isogonic line labeled 10°E passes through all points on the chart where the variation is 10°E. Note that the compass needle will not necessarily be parallel with the isogonic line. An isogonic line for 0° variation is called an **agonic line.** In certain areas, variation is very erratic. Sometimes it varies as much as 80° in less than

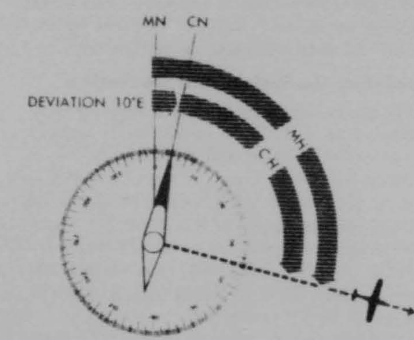


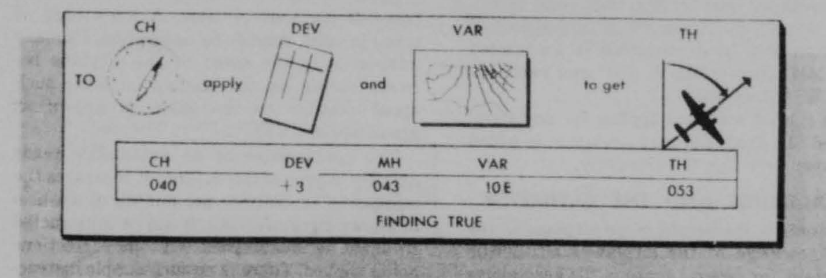
a mile, though this is unusual. Such areas are marked on charts. The variation is more nearly normal at higher altitudes.

The variation at any one point changes from year to year in a somewhat rhythmical fashion. The extremes of the change may exceed 50° over a long period. The year for which the isogonic lines are drawn is indicated on aeronautical charts. Sometimes the annual change also is indicated. Usually, however, the aeronautical chart is obsolete for other reasons long before the change in vari-









THIS PAGE IS DECLASSIFIED IAW EO 13526

ation is great enough to cause difficulty.

Usually variation offers no problem. It is simply read from the chart. If variation changes only 2° or 3° in the length of a flight, the average of the variation at departure and that at destination is used. If the change is more than about 4°, the flight is divided into legs and the average for each leg is used.

Deviation is not quite so simple since deviation varies with heading. Generally, deviation is determined for headings of intervals of 15°. This information is entered on a deviation card. The navigator consults this card for the deviation for any particular heading.

Deviation may change with any change in electrical equipment or iron in the airplane. For example, deviation may change when bombs are dropped or ammunition is expended. It may even change with the jolt of a hard landing. And, it changes somewhat with latitude. The deviation card should be approximately correct but it is not necessarily exact. Deviation from the card is used when no better information is available; but when possible, deviation is checked in flight by the use of the astro-compass or driftmeter.

Applying Variation and Deviation

TH can be found by applying deviation and variation to CH. This operation is simply a matter of addition and subtraction.

When variation is east, magnetic north is east of true north. MH, measured clockwise from magnetic north, is less than TH measured clockwise from true north. Therefore in order to find TH from MH, east variation is added to MH. Thus if MH is 050° and variation is 10°E, TH is 060°.

Similarly, when variation is west, magnetic north is west of true north and MH is larger than TH. Therefore, in order to find TH from MH, west variation is subtracted from MH. Thus if MH is 070° and variation is 10°W, TH is 060°.

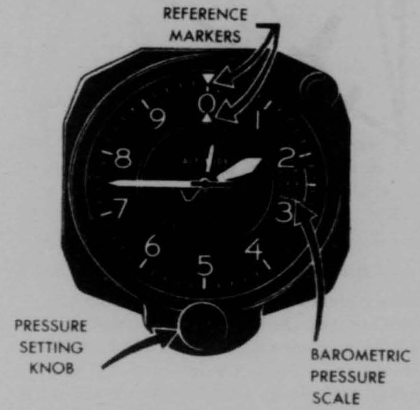
The rule of variation applies for deviation. To find MH from CH east deviation is added and west deviation is subtracted.

14. ALTITUDE AND THE ALTIMETER

Altitude is the height of an airplane in the air. Knowledge of the airplane's altitude is important for several reasons. To keep above dangerous mountain peaks, one must know the altitude of the airplane and the elevation of the surrounding terrain at all times. This is especially important when visibility is poor and one must fly high enough to clear the highest terrain or obstructions in the area one estimates himself to be.

Often a certain altitude is flown to take advantage of favorable winds and weather conditions. Furthermore, altitude is used in the calculation of certain data, such as true airspeed.

Altitude may be defined as vertical distance above some point or horizontal plane used as a reference.

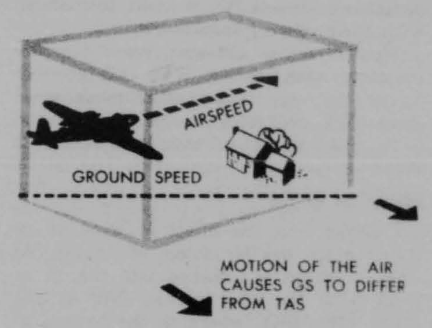


15. AIRSPEED AND THE AIRSPEED INDICATOR

General

Speed is rate of motion or the distance traveled per unit of time. A knowledge of speed is indispensable to navigation. Primary interest is in the speed of the airplane between points on the earth's surface; such speed relative to the earth is known as **groundspeed (GS).**

The speedometer of an automobile reads directly in groundspeed. Since it measures the number of revolutions per minute of a wheel of known circumference, it can be constructed to show accurate speed without corrections being applied. There is no such simple instrument to give the groundspeed of an airplane



directly. Groundspeed may be found in various ways, but each way involves calculations.

It is possible to measure by instruments the speed of an airplane through the air. This is known as **true airspeed (TAS).** If the air were still with relation to the earth, groundspeed would equal TAS. But, the air is almost constantly in motion. This motion of the air relative to the earth is called wind. If the airplane flies with the wind, groundspeed is greater than TAS; if it flies against the wind, groundspeed is less than TAS. However if the wind, the TAS, and the true heading are known, the GS can be found.

The Airspeed Indicator

The instrument which measures airspeed is an **airspeed indicator.**

Computing True Airspeed

The reading of the airspeed indicator depends not only on the TAS of the airplane but also on the density of the air through which the airplane is flying. Pressure difference increases with TAS. If density is twice as great, there are twice as many particles of air in a given volume. At the same TAS, therefore, an airplane collides with twice as many particles of air, and the pressure difference increases. Since the airspeed indicator measures pressure difference, its reading increases with density of air as well as with TAS.

The airspeed indicator is designed to read TAS under standard sea-level conditions, that is when pressure is 29.92" and temperature is 15°C. Air density decreases with altitude;

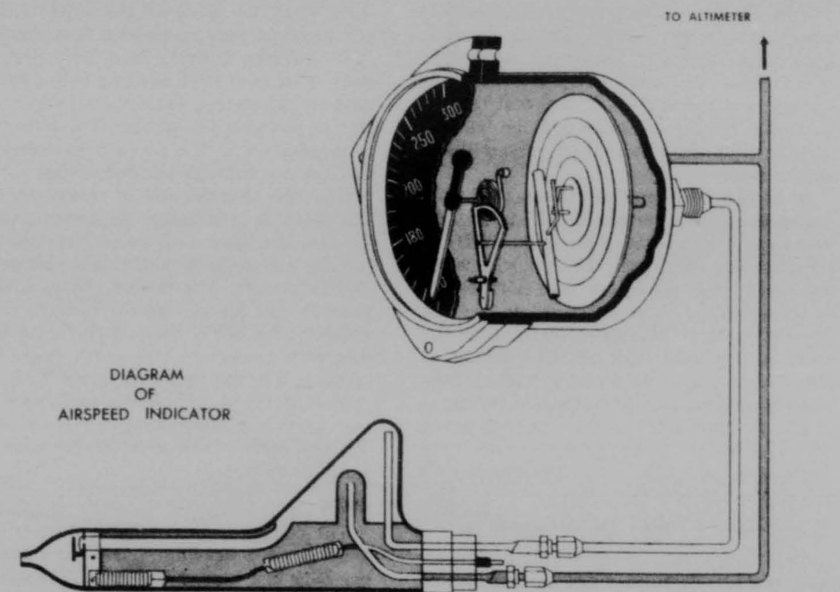


DIAGRAM OF AIRSPEED INDICATOR

therefore at higher altitudes the airplane has to fly faster to cause the same pressure difference. Thus for a given TAS, IAS decreases with altitude. Or to put it another way, for a given IAS, TAS increases with altitude.

IAS is corrected for temperature and pressure by means of the airspeed correction scale on the E-6B computer. This scale is opposite the altitude correction scale. In the window is a scale of pressure altitude readings from approximately —1,000 ft. to +34,000 ft. Above it is an air temperature scale reading from approximately —50° to +50°.

16. WIND AND DRIFT

General

If the air in which airplanes fly were absolutely still, aerial navigation would be very simple. In fact there would be little need for a specially-trained navigator, and this chapter would not be necessary. The pilot, merely by correcting for variation and deviation, easily could set the airplane on any desired course. He could calculate estimated times of arrival and determine positions en route by using the true airspeed.

Unfortunately, however, this situation seldom, if ever, exists. Wind makes the air navigator and his costly equipment necessary. It has been said that navigation is wind-finding; and this statement is almost true. A navigator must continually find the wind if he is to obtain the results required in military air operations.

Wind is a horizontal movement of the air across the earth's surface. Wind has both direction and speed. **Wind direction (WD)** is the direction from which the wind is blowing, measured with respect to true north. Like other directions it is expressed in degrees from 0° to 360°. Thus, if a wind is from the west, it is a west wind and its direction is 270°. Note that wind direction differs from other directions used in navigation in that it is the direction from which, rather than the direction toward which, motion occurs. True heading, for example, is the direction toward which the airplane is headed.

Wind Speed (WS) Or Wind Force

This is the rate of movement of the air over the earth's surface. Meteorologists and navigators express WS in knots to conform with their other measurements.

Wind direction and wind speed together constitute **wind velocity (WV).** It is incorrect to use the word "velocity" to mean speed alone. "WV, 180°/25K" means that the wind is from the south and that its speed is 25 knots.

Effect of Wind

Consider first the effect of wind on an object which has no motion of its own. At 0900 a balloon is launched into the air at point A. If the wind is from 270° at 20K (WV, 270°/20K), where is the balloon at 1000? The balloon may be thought of as floating in a body of air which moves from 270° to 90° at 20K. In one hour the body of air moves 20 n.m., and the balloon with it. Thus at 1000 the balloon is at point B, 20 n.m. from point A in a direction of 90°. A balloonist never feels any wind. He is suspended in the body of air and moves with it. No air moves past him. A balloon in the air is just like an empty bottle floating down a river.

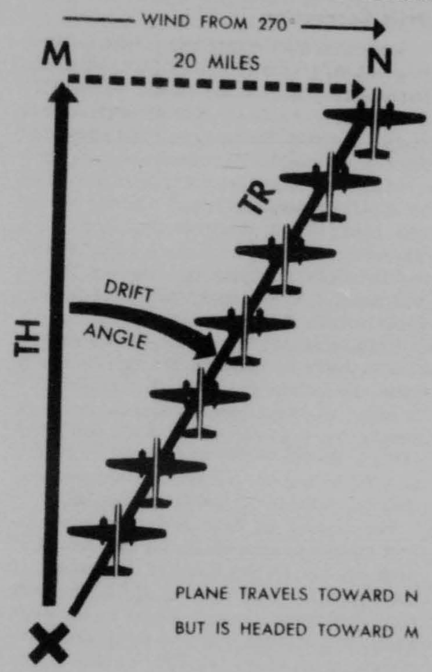
Any free object in the air moves downwind with the speed of the wind. This is just as true of an airplane as it is of a balloon. If an airplane is flying in a 20K wind, the body of air in which it is flying moves 20 n.m. an hour. Therefore, the airplane also moves 20 n.m. downward in an hour. This movement is in addition to the forward movement of the airplane through the body of air.

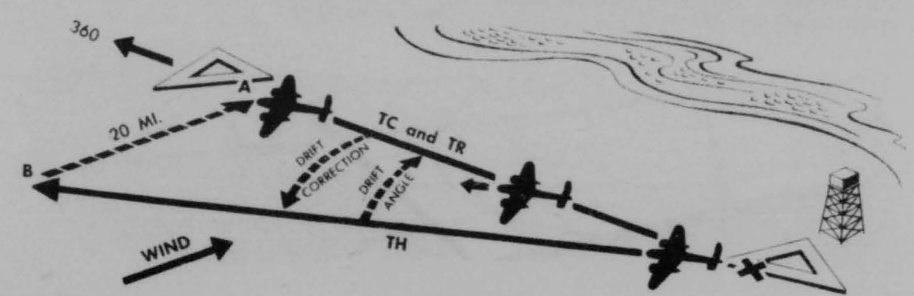
It is clear that the path of an airplane over the earth is determined by two unrelated factors: the motion of the airplane through the air, and the motion of this air across the earth's surface. The motion of the airplane through the air is directly forward in response to the pull of the propellers; its direction with respect to true north is the true heading, TH and its speed is the TAS. The motion of the air across the earth's surface may be in any direction with respect to the TH; its direction and speed of course are the wind velocity.

Drift

The plane in the next figure departs from point X on a heading of 360° and flies for one hour in a wind of 270°/20K. The airplane is headed toward point M, directly north of X, so its TH is represented by the line XM. If there were no wind, the airplane would be at point M at the end of the hour. However, there is wind. The body of air in which the airplane is flying moves 20 n.m. in the hour and the airplane moves with it. Consequently, at the end of the hour the airplane is at point N, 20 n.m. downwind from M. Thus, the line XM is the path of the airplane through the body of air; the line MN shows the motion of the body of air; and the line XN is the actual path of the airplane over the earth. The actual path of the airplane is the **track (TR).** Track should be distinguished from true course (TC) which is the intended path of the airplane.

The sideward displacement of the airplane by the wind is called drift. Drift is measured





THIS PAGE IS DECLASSIFIED IAW EO 13526

by the angle between TH and TR; this is the drift angle. In the example, the drift angle is MXN, the angle betwen the heading XM and the track XN. The plane has drifted to the right; this is known as right drift.

A given wind causes a different drift on each different heading. It also affects the distance traveled in a given time. Therefore, with a given wind the GS varies on different headings.

Drift Correction

Suppose a pilot wants to fly from point X to point A, a true course of 360°, when the wind is 270°/20K. What should be the TH? Obviously, if he flies a TH of 360°, he will end up, not at A, but at some point downwind from A. Rather, he must head for some point upwind from A and let right drift bring him to A. If the airplane is to be in the air for one hour, it will drift 20 n.m. downwind. Therefore, he must head for a point 20 n.m. upwind from A. Flying the heading XB, he will reach A in one hour; the TR of the airplane will be XA.

Heading an airplane upwind from destination in order to maintain the true course is called correcting for drift. The angle AXB is called the drift correction angle or, more simply, the drift correction. **Drift correction (DC)** is the correction which must be applied to a TC to find the TH needed to make good that TC. AXB is a left drift correction.

The amount of drift correction must be just enough to compensate for the amount of drift on the correct heading. Therefore, if the airplane is on a heading of XB, the drift correction angle must be equal to the drift angle. But, if drift is to the right, drift correction must be to the left. Therefore the drift correction angle is measured in the opposite direction to the drift.

Remember that after a navigator has corrected for drift, the airplane will still drift. All he has done is to head the airplane off course so that the wind will cause it to drift back on course. Changing the heading of the airplane will not turn off the wind.

Drift correction is usually found in the air by one of the following methods:

a) Reading the drift correction directly from the driftmeter. The disadvantages of the driftmeter are that the ground must be visible and that accurate drift is difficult to obtain if the airplane is 9,000 ft. above the terrain or over 4,000 ft. above the water, or if the water is smooth.

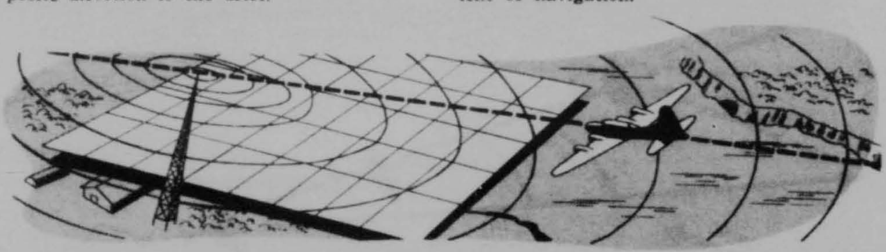
b) The drift correction usually is found by solving the wind triangle, which will be discussed later.

17. DEAD RECKONING AND AIDS TO DEAD RECKONING

Precision Dead Reckoning

The navigator has three basic problems: locating his position at any time, calculating the time at which he will reach any point, and calculating a TH to bring the airplane to any desired destination.

Dead reckoning is the method of solving these three problems by means of measurements and calculations involving time, a known position, and one or more of the three velocities: TR-GS, TH-TAS, and WD-WS. These calculations are made with the time-speed-distance formula and the wind triangle. Dead reckoning is the navigator's basic method because it is the only means of solving all three of these basic navigational problems. In a sense, then, dead reckoning is the equivalent of navigation.



Location of Position

There are three methods of locating position during flight. One depends on external means, and the other two are forms of dead reckoning.

Fixes. By map reading, radio or celestial means, the navigator can locate the position of the airplane without the use of dead reckoning. When he finds on a chart the position of a landmark which is directly beneath the airplane, he has located his position by map reading. Similarly, by radio and celestial, he locates position by external means. This is called fixing the airplane's position; and the position he finds is a fix.

Basic Dead Reckoning. If the location of the departure point is known, the time of departure, the TR and GS of the airplane, and the position of the airplane for any time can be found. The departure point is plotted on a chart. Subtracting the time of departure from the time of the desired position, the time on course can be found. By means of the time-speed-distance formula, the distance flown in this time at the known GS can be found. From the departure point on the chart, this distance is laid off in the direction of the known TR. Thus, the desired position is established. This is a dead reckoning position or **DR position** as distinguished from a fix.

This process is perhaps the most fundamental application of the dead-reckoning method. Therefore, it is often called basic dead reckoning. Thus, in basic dead reckoning, known position, the elapsed time, and the TR-GS vector are known. The wind is not known.

Precision Dead Reckoning. If the location of the departure point, the time of departure, the TH and TAS of the airplane, and the wind velocity are known, the position of the airplane for any time can be found.

Calculation of Time of Arrival

There is only one method of finding the time at which an airplane will reach any given point. A navigator must know the time of departure from some position, the distance to the given point, and the GS which the airplane wil make on the TC to the point. By means of the time-speed-distance formula, he can find the time required to fly this distance at this GS. He adds this time to the time of departure in order to find the time of arrival at the given point.

Dead Reckoning

The methods described are the only methods of solving the three basic navigational problems. Because the second and third problems can be solved only by dead reckoning, dead reckoning is essential to navigation. Map reading, radio, and celestial observation can solve only the problem of location; they cannot solve the other two. Therefore, they are not distinct methods of navigation comparable to dead reckoning. However, by solving the problem of location, they give information which helps to solve the other two problems. Thus, they are a source of dead-reckoning data. Therefore, map reading, radio and celestial are called aids to dead reckoning.

Precision dead reckoning is the only single method of solving all three of the basic problems. Basic dead reckoning will solve only the first and second problems, and it will solve these only under special conditions. Because precision dead reckoning is the only complete method, precision dead reckoning is carried on continuously during flight.

Procedure of Precision Dead Reckoning

Precision dead-reckoning procedure involves more than the mathematical solution of the three basic navigational problems. It includes also the procedure by which the navigator plans his work and continually sets these problems for himself; it includes much of the method by which he obtains the information necessary for their solution. He obtains this information from two sources: the flight instruments—the compass, airspeed indicator, driftmeter, clock, free air temperature gauge, and altimeter—and the aids to dead reckoning. Thus, precision dead reckoning includes the reading of the instruments. It also includes the determination of wind, TR, and GS from the fixes given by the aids to dead reckoning; but it does not include the actual use of the aids to obtain these fixes. Thus, precision dead-reckoning procedure involves practically all the navigational activities except the calibration of instruments and the actual use of map reading, radio and celestial.

If the navigator can read drift, he can do precision dead reckoning by the flight instruments alone. However, if the ground is obscured so that he cannot read drift, he must rely on one of the aids to dead reckoning for information both as to his position and as to the wind. Moreover, even when he can read drift, the establishment of positions by instrument dead reckoning alone is subject to small errors. As he travels farther from a known position, these errors may accumulate into large errors. Hence, in order to correct his dead reckoning, he must establish definitely his position from time to time by one of the aids.

18. MAP READING

General

Map reading is the identification of landmarks with their representations on a chart. Map reading can be the most accurate of the aids to dead reckoning. The accuracy of a celestial or radio fix is usually in doubt; but when an object on the ground has been identified on an accurate chart the exact location of the plane is known. The aeronautical charts which are used in the United States are relatively accurate and complete; but in other parts of the world accurate information is not available. Obviously map reading cannot be more accurate than the charts being used.

19. OTHER AIDS TO DEAD RECKONING

The Automatic Radio Compass

For the navigator, the principal value of the automatic radio compass is its ability to give a continuous and automatic bearing on any radio station within the frequency and sensitivity of the radio set that is in the airplane. When the radio set is properly tuned and adjusted, the azimuth indicator (radio compass pointer) points toward the station. This property of the radio compass is used in two ways: for homing and for radio fixes.

Homing. If the heading of the airplane is adjusted so that the azimuth pointer always points to the triangular index the airplane will be headed approximately toward the radio station. The relative bearing between the airplane and the radio station is then zero. When the pointer swings 180° the airplane is passing over the radio station. This is the most common use of the radio compass.

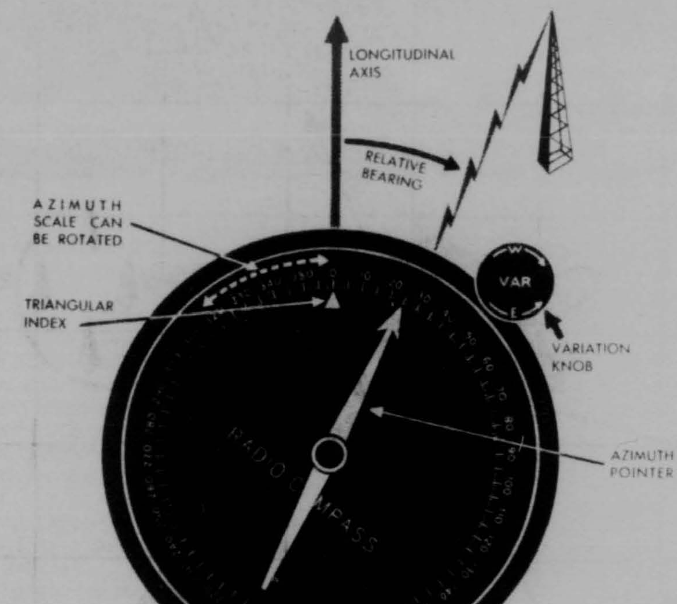
Radio Fixes. Since the azimuth pointer points toward the radio station, the number of degrees that the pointer differs from the longitudinal axis of the airplane can be determined by reading the radio compass. This is known as a **relative bearing (RB).** If this relative bearing is added to the true heading of the airplane, the **true bearing** (angular distance from true north) of the airplane from the station can be found. This is done mechanically by setting the true heading at the triangular index by rotating the azimuth scale with the variation knob. To the true bearing, 180° is added to get the true bearing of the radio station from the plane since the radio station's position is known. This can be accomplished mechanically by simply reading the azimuth scale at the tail of the pointer. Now if this true bearing is plotted from the radio staion, the position of the airplane will be on the line drawn **(LOP): line of position.** If this procedure is repeated for another radio station and its true bearing drawn, the two lines will intersect showing the approximate position of the airplane. This is known as a radio fix.

Celestial Navigation

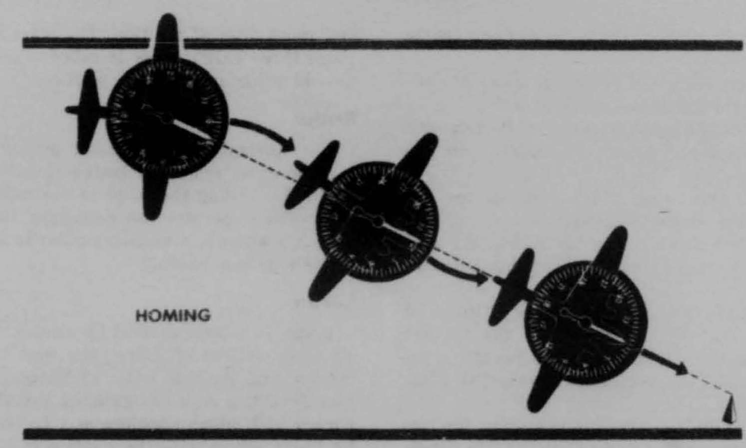
Celestial navigation is the employment of celestial bodies—the stars, sun, planets and the moon—to determine position. The Egyptians used celestial navigation prior to 2000 B.C. This means navigation was used on the Mediterranean by the Greeks, Phoenicians, Carthaginians and later the Romans.

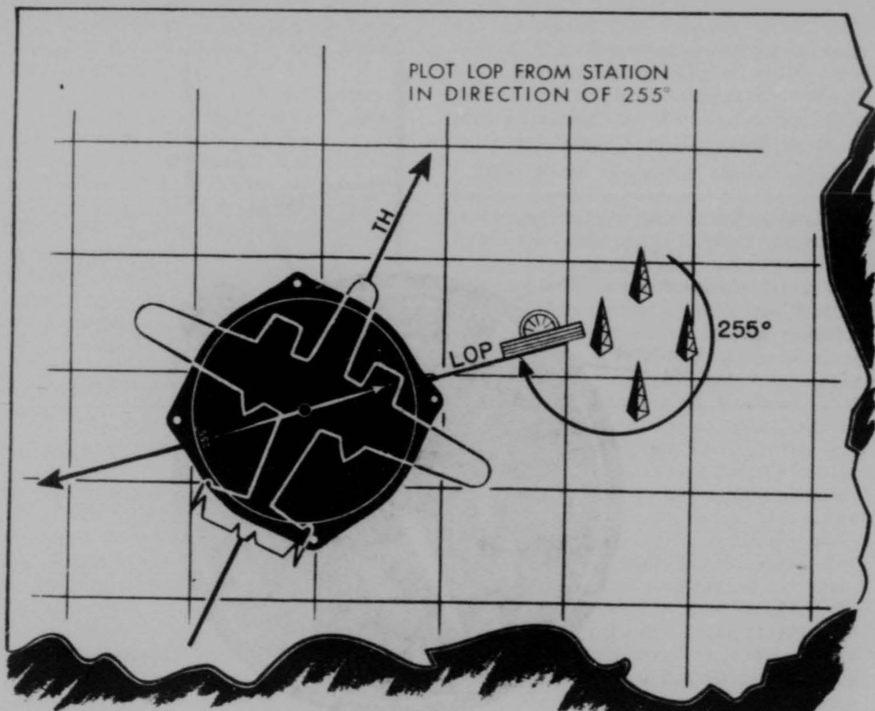
Very briefly, here is an explanation as to to how a navigator finds his position of the earth by celestial means.

Astronomers and mathematicians have made a set of tables from which the altitude or angular distance above the horizon of any visible celestial body can be found for any particular moment in the day for any position on the earth. The navigator has a sextant, more correctly called an "octant," which is an optical instrument for the determination



AZIMUTH INDICATOR





of the altitude above the horizon of any visible celestial body.

The navigator can determine a line of position from Polaris, the North Star, by:

a) Making an observation of Polaris with his sextant and noting the time of the observation.

b) Determining a DR position for the same time as the observation.

c) Consulting his tables to find the altitude of Polaris for this time at this DR position.

d) Then by comparing the altitude of Polaris that he obtained from the sextant with the altitude of Polaris he found for his DR position, the navigator can establish a line of position.

Now if he repeats this operation for two more stars, Altair and Deneb, he will obtain two more lines of position. The place where these three LOP's cross is called a celestial fix and is his approximate position.

Radar

The navigator is interested primarily in the radar set made for installations in aircraft. By reading the scope of the radar set, the trained operator can determine the airplane's position in a manner similar to finding position by map reading.

Loran

Loran is a term derived by combining the first two letters of LOng, the first two of RAnge, and the first letter of Navigation. It was developed as a navigational aid. The accuracy with which positions may be obtained by Loran varies with the location of the air-

craft relative to ground stations, and with other conditions of transmission and reception.

The effective range of Loran over sea water is about 600 to 700 nautical miles in the daytime, and 1200 to 1400 at night. This great range is achieved by the use of relatively low radio frequencies, just above the standard broadcasting band, which can propagate over the curvature of the earth.

Briefly, here are the principles of Loran operation:

a) Radio signals consisting of short pulses are broadcast from a pair of ground-based transmitting stations.

b) These signals are received on a specially-designed Loran radio receiver located in the aircraft.

c) The difference in time of arrival of the signals from the two radio stations is measured on the Loran indicator.

d) This measured time difference is utilized to determine directly from Loran charts a line of position on the earth's surface.

e) Two lines of position, determined from two pairs of transmitting stations, are crossed to secure a Loran fix.

Thus, Loran is entirely different from radio direction-finding, for Loran measures the time of arrival of radio waves, rather than the direction of arrival.

Loran is different from radar in that there is no transmission from the aircraft. Loran has, however, borrowed from radar some of the radar techniques for measuring time to millionths of a second, and techniques for visually observing signals on a cathode ray tube.

20. FEDERAL AIDS TO NAVIGATION

Introduction

Government-established and maintained airways in the United States, as well as in

other countries, are of great help to the pilot and navigator. In effect, the airways are air highways. They form a network linking all important points in the country. They reduce problems of navigation to standardized methods which work at any time and place and in all weather conditions. Traveling on the airways, a pilot can go virtually anywhere in this country, and at no time will he be more than fifty miles from an airport. In thinly-populated areas, where there otherwise would be no airports, the Government maintains intermediate landing fields at intervals of about fifty miles along the airways.

Besides the landing fields, airway aids include radio range stations, rotating beacon lights, radio marker beacons, and weather information.

Radio and lighting aids are marked in red or purple on sectionals and regionals, and other charts showing aeronautical data. The symbols for these aids are shown in paragraph 4e of section V, chapter 00.

Radio Range Stations

Radio range stations in the United States are spaced at intervals along all airways and are located near important airports. The distance between the ranges and the power output of the stations usually make it possible to receive several nearby ranges from any point along the airways.

At least two of the on-course legs of a range station are directed along the center line of the airway, one in each direction. This provides directional guidance on the airway both in approaching and departing from the range station. An airplane equipped with any receiver which can be tuned to range frequencies (200-410 kc) can follow the airways without sight of the ground.

Rotating Beacon Lights

The airways are marked at night by rotating beacon lights, which are spaced at intervals of approximately ten miles. Seen from the air, the beacons form an on-course light line visible from twenty to forty miles. Aeronautical charts indicate each beacon by a star with an open center, and arrows with this symbol indicate the beacon has course lights and show the direction of the light line.

The location of a beacon on an airway is flashed in an identifying code letter which shows its distance from the origin of the airway. Beacons are numbered from west to east and from south to north between terminal cities. The number of the beacon, multiplied by ten, gives its approximate distance in miles from the origin of the airway. For example, beacon No. 1 is ten miles from the origin of the airway, and beacon No. 5 is fifty miles.

The beacon number is identified by a letter flashed in International Morse code. The first letter of each word in the following sentence corresponds to the number given with it:

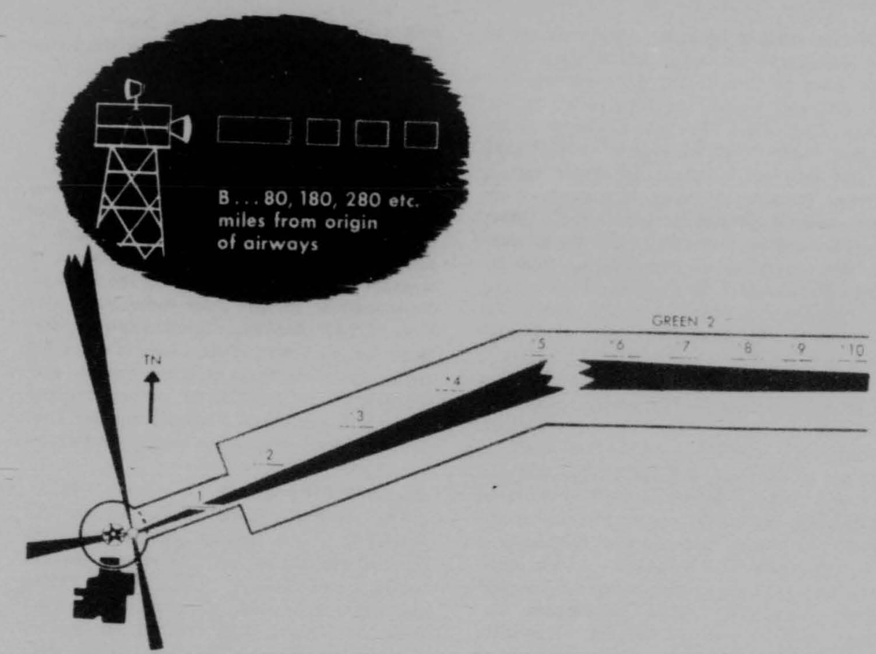
(1) When (2) Undertaking (3) Very (4) Hard (5) Routes (6) Keep (7) Directions (8) By (9) Good (10) Methods.

Because only ten letters are used, it is necessary that the same letters represent beacon numbers of beacons that are more than 100 miles from the origin of the airway. The number of a beacon more than 100 miles and less than 1,000 miles from the origin of an airway is a two-digit number; the code letter flashed by the beacon represents only the last digit. Thus "W" is the code letter for beacons numbered 1, 11 and 21, which are respectively 10 miles, 110 miles and 210 miles from the origin. Likewise, "U" is the code letter for beacons numbered 2, 12, 22, etc. Thus the series of code letters is repeated for each 100-mile section of the airway; this presents no problem because the navigator should know which 100-mile section of the airway he is on.

Airway beacons show six clear flashes per minute. The identifying code letter, displayed between flashes, is visible only to airplanes on course. The letter is flashed in green if the beacon is located at an airport; if not, it is flashed in red. The number of the beacon, as well as the corresponding code signal, is printed beside the beacon symbol on aeronautical charts. The number also is painted on the roof of the beacon power shed for daytime identification.

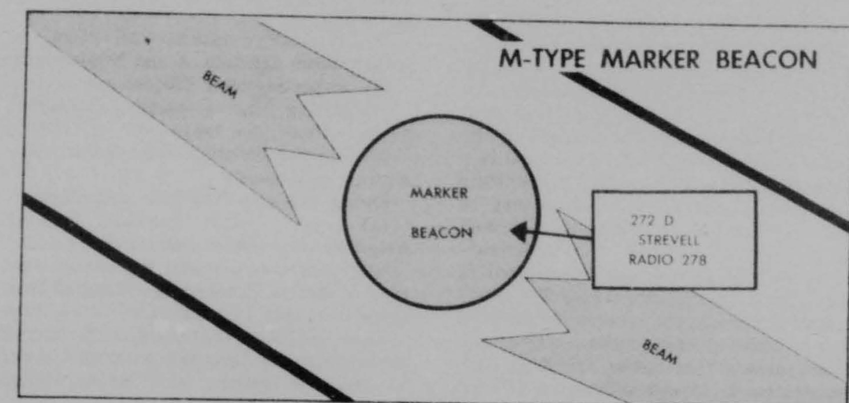
Radio Marker Beacons

The main purpose of marker beacons is to assist the navigator or pilot in obtaining fixes at the range station and along the airways at intermediate points between range stations. The principal types of marker are the



M-, Z- and fan-types.

M-Type Marker Beacon. This type of beacon is a low-powered, non-directional radio station which transmits a characteristic signal, such as "R" (dot-dash-dot), once every few seconds. It is usually equipped for voice communication with aircraft. Its range is from three to ten miles, depending on the weather and the type and condition of the receiver.



M-type marker beacons, usually placed at the intersection of two range courses, indicate when to tune to the next station. The characteristic signals are transmitted on the same frequencies as the adjacent radio ranges; thus the marker signals can be heard if the receiver is tuned to either range. Marker beacons also may be placed on or near some obstruction, such as a radio tower or at some particular point along the airway. The M-type beacon does not operate continuously. It is turned on when the local ceiling is more than one-tenth overcast, when the visibility is less than five miles, or at any time on request.

Z-Type Marker Beacon. Because the cone of silence does not always provide a positive and reliable means of determining the exact position of a radio range station, Z-type markers are installed at most radio range stations for this purpose. A special receiver must be installed in the airplane to receive the signals which are transmitted on a high frequency—75 megacycles. The Z-marker antenna localizes the signal zone within a teardrop-shaped space immediately above the station. The signal may be received visually or aurally, depending on the receiver; but visual reception only is provided by USAF receivers. The marker beacon light, on the pilot's instrument panel, flashes on as the airplane enters the cone of silence and remains on until the airplane emerges from the cone. The duration of the Z-marker signal increases with increasing flight altitude.

Fan-type Marker Beacon. Fan markers are high frequency (75 megacycles) radio transmitters usually installed twenty to thirty miles from the radio range across one or more of its on-course signals. They are not equipped for voice transmission. The antenna of the beacon produces a high intensity signal in a space shaped like a thick fan, immediately above the transmitter. This signal may be received either visually or aurally, depending on the receiver; in USAF aircraft, it is received visually by the equipment used to receive the Z-type marker signal. The markers around a range station may be identified by a succession of single dashes, or by groups of two, three or four dashes. The single-dash identification is always assigned to the on-course leg directly true north from the station or to the first on-course in a clockwise direction from true north. The groups of two, three or four dashes are assigned respectively to the second, third and fourth courses clockwise from the single-dash beacon.

Weather Information

The federal airways get weather information from the U. S. Weather Bureau and the Civil Aeronautics Board. This information is sent in hourly teletype sequence reports to weather-reporting stations along the airways. Such stations include most radio range stations, USAF Airways Communications Stations, airport traffic control towers and CAB radio communications stations. Besides giving weather information on request for any vicinity, the stations transmit regular local weather broadcasts on the twenty-ninth minute of every hour.

Radio Facility Chart

The **Air Force Radio Facility Chart,** T.O. No. 08-15-1, is a manual of important data on airports, radio range stations, marker beacons, and airways in the United States and southern Canada. In the main section are thirty-five charts, each covering one section of the United States. The code symbols, definitions and rules used on these charts are explained on Pages 2 and 3 of the manual. An index map on the back cover shows which chart to use for a given area.

Each chart shows:

(1) Airways—color, minimum safe altitude to fly in each direction, the control area they lie within.

(2) Radio range stations—call letters, frequency, beam direction, A and N quadrants.

(3) Airports—tower frequencies.

(4) Marker beacons—name, code, signal, distance from radio range.

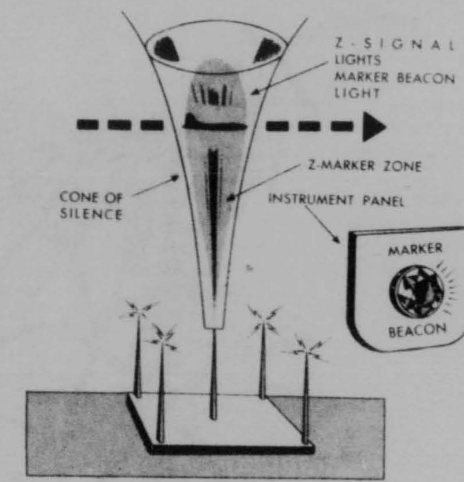
(5) Nondirectional homing beacons transmitting continuously.

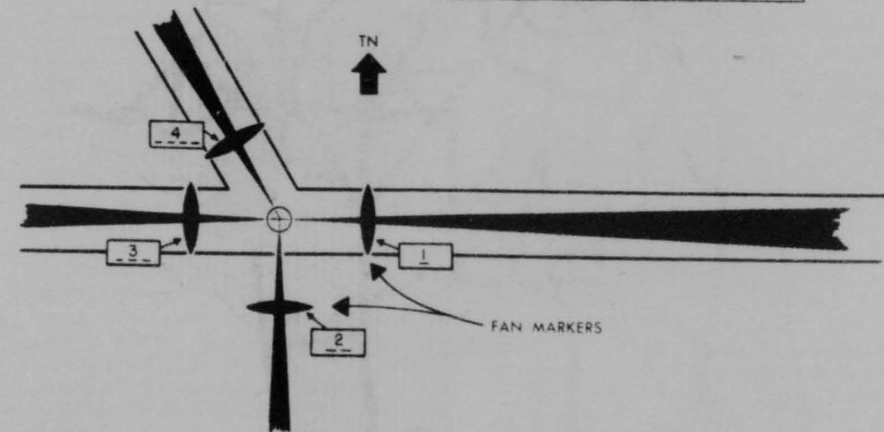
Facing each chart is a table which lists:

(1) Airports—name, frequency guarded, frequency broadcast and elevation.

(2) Radio ranges—name, call letters, code, class of station, distance, and direction from range to airport (if any).

These additional charts are in the back of the manual: (1) Geographical coordinates of all radio navigational aids in the United





States.

(2) List of radio aids to navigation—call letters and frequency.

(3) Charts showing danger areas, training areas and obstructions.

In the center of the volume is the planning chart which shows the entire United States, all radio range stations, and their distances apart along the airways.

Airways Traffic Control

Every military pilot is required to obtain approval of his flight plan before he departs on any flight other than a local flight. In good weather, when the airplane is on **Visual Flight Rules (VFR),** notification of the ETA is wired from the point of departure to destination.

Airway Traffic Control (ATC) is the agency in charge of every flight in bad weather. When aircraft are on **Instrument Flight Rules (IFR),** ATC approves their flight plan in respect to known air traffic conditions. After such approval, pilots must comply strictly with the approved flight plan, except in emer-

AIRWAYS MAP OF UNITED STATES SHOWING AIRWAY TRAFFIC CONTROL CENTERS

RESTRICTED

gency. Before any change is made en route, the change must be approved by ATC.

All calls to ATC from the air are relayed through range stations, operated by USAF Airways Communications stations or control towers. ATC cannot be contacted from the air. While en route, the pilot must report the progress of his flight to ATC. At ATC centers, this information is recorded on plotting boards which show the altitude and time separation of various instrument flights along the airways.

Airway Traffic Control centers, located at junction points along the airways, are shown on the radio facility charts. Airplanes on instruments must contact the ATC center before crossing or entering an airway.

Each of the four airways listed on the facility charts has a designated color. Green and red airways run east and west; amber and blue airways run north and south. Airplanes flying north or east must fly at an odd altitude (that is, 1,000 ft., 3,000 ft., 5,000 ft., etc.); those flying south or west must fly at an even altitude (that is, 2,000 ft., 4,000 ft., 6,000 ft., etc.). While on airways, airplanes always must be flown to the right of the beam. The altitude shown on each airway in the radio facility chart is the minimum safe altitude for that section of the airway.

Each airway has a priority rating. Green has priority over amber, amber over red and red over blue. The name G-A-R-B-O will help in remembering this order of priorities. At airways intersections, the airplane which is flying on the right-of-way airway will maintain its altitude; the airplane on the other airway must climb 500 ft. The "O" in Garbo means off the airways—no priority.

Airport traffic control towers are maintained at most airports. During VFR conditions, the tower operators have control over air traffic in the vicinity of the airport, directing take-offs, landings, taxiing, and related maneuvers.

Other Radio Aids

Marine Marker Beacons. These beacons are small radio transmitting stations, usually arranged in groups of three along a sea coast. Transmitting on the same frequency, they make it possible for the navigator to take three bearings with a minimum of tuning. One station sends its identification signal (a letter in International Morse code) for one minute; then the other two stations follow in turn. This procedure is repeated three times during a schedule and in clear weather two schedules per hour are usually transmitted; in bad weather they are repeated continuously. The reliable range of these stations, which were designed primarily for marine navigation, is from 10 to 200 miles, depending on the power of the transmitters. On aeronautical charts, the symbol for the marine marker beacon is a dot within a circle, or a solid circle with the letters RBn beside it. In a box adjoining the symbol are the call letters, frequency, and schedule of transmission.

Radio Direction Finder Stations. Radio direction finder stations, which are located along the coast and used mainly by naval forces, take bearings on the transmitters of ships and airplanes. As a rule, RDF stations are arranged in groups of three, with one of the three designated as the master and plotting station.

To request that a group of RDF stations fix the airplane's position, the radio operator sends the master station the appropriate **"Q" signal (QTF).** (Q signals covering many types of request are listed in AACS Manuals.) The radio operator then awaits instructions.

The master station, after notifying the other stations of the RDF group, directs the airplane to send its identification signal followed by a 20-second dash, repeated as many times as requested by the station. Then the other stations take bearings on the airplane and telephone them to the plotting station. Here the bearings are plotted, the fix evaluated, and the results transmitted to the airplane. If the RDF stations cannot obtain good bearings, the word "doubtful" will accompany the results. The entire procedure takes only a few minutes.

On aeronautical charts, each RDF station is indicated by a dot within a circle, with the letters "RC" near the circle. In a box beside the symbol are the station's call letters and frequency. The normal RDF frequency is 375 kcs. All coastal RDF stations use this frequency; in case of emergency they will take bearings on a 500 kc. transmitter.

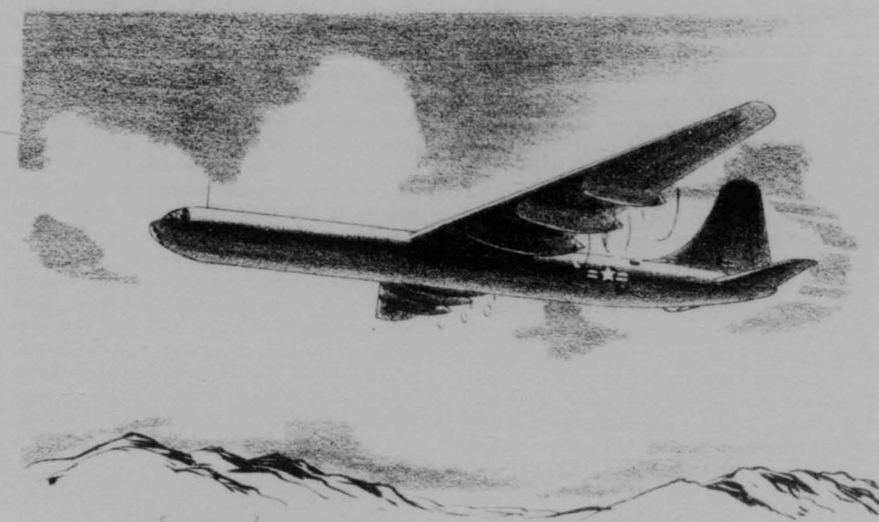
Part 3 - APPLIED AIR POWER

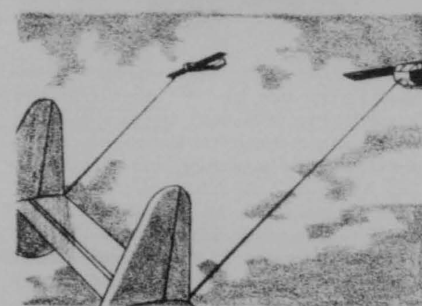
THIS PAGE IS DECLASSIFIED IAW EO 13526

CHAPTER I - TYPES OF MILITARY AIRCRAFT



SECTION I - GENERAL

Military aviation as we know it today stems from the flight of the Wright Brothers, since almost all present-day military aircraft are of the heavier-than-air variety. However, mankind has thought about flying and experimented with flying throughout recorded history. Ancient peoples endowed their deities with the power to fly. The idea that man could fly has been one of the most persistent ideas down through the ages. "Our modern progress in aviation," writes Professor Berthold Lanfer of the Field Museum of Natural History, "is not solely due to efforts of the present generation, stupendous and admirable as they may be, but presents the process of a gradual evolution of ideas which have grown out of the imagination, endeavors, experiments, triumphs, and failures of many past ages."



When the Wright Brothers did finally free man from the earth by building their flying machine, considerable attention had already been paid to the idea of aerial warfare. The fact that so much of the development of aviation has been predicated upon its potential use in warfare is unfortunate: but today, we are in a position that enables us to look forward

THIS PAGE IS DECLASSIFIED IAW EO 13526

to the time when a strong air force will make costly surface warfare unnecessary.

With the advent of the heavier-than-air craft, the way was open to really develop the air weapon. The airplane was used to considerable extent in World War I and, by 1920, had really begun to prove itself. It was no longer merely the eyes of the Army. British fighters had fought off Zeppelins on their way to London. The German fighter had, for a time, been predominant in aerial combat because it mounted machine guns which fired through the propeller. Aerial bombardment had raised the prestige of the air weapon. Planes had flown several hundred miles into enemy territory to bomb selected targets and other missions had been assigned to aid the armies in the field.

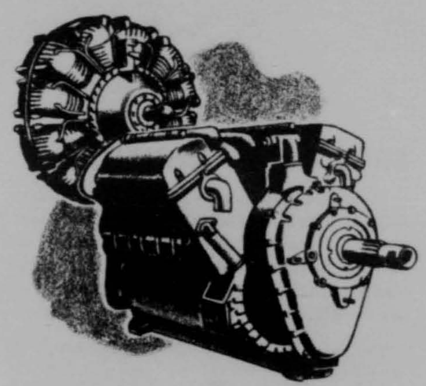
The best heavier-than-air bombardment aircraft of World War I were able to drop but a half a ton of explosives on a target and most bombers were capable of carrying only a few hundred pounds for short distances. The numerous bombing raids which were flown during the conflict had little effect upon the outcome.

The United States had been caught almost totally unprepared for air action in World War I. American-built aircraft did not start to reach the combat zone in any large numbers until the end of the war, and then they were an adaptation of a European design. The greatest achievement in aviation production attributed to this country was the Liberty engine. This engine, created jointly by several designers, turned out to be a lifesaver for the fledgling aircraft industry. By the end of the war, the Liberty engine was being produced at the rate of 46,000 per year.

When the first World War ended, we had some British-designed De Havilands and the old Curtis Jenny, neither of which had much range or speed. During the succeeding years, the design and capabilities of the airplane showed decided progress. In 1923, a coast-to-coast, nonstop flight was made. A group of Army officers had flown around the world. Jimmy Doolittle and others were pushing the speed mark up to 250 miles per hour and new endurance records were set.

In these post-war years airmen also were becoming aware of the fact that the development of the airframe was exceeding that of the power plant. When the B-15 and the B-19 were built, they were the largest land planes ever constructed. Yet neither ever became more than an experimental plane, principally because no engine had been developed with the power required to give the airplane its best performance. This was true of many of the aircraft of this period.

A constant argument had been going on for many years concerning the relative merits of the in-line, liquid-cooled, reciprocating engine and the radial, air-cooled, reciprocating engine. The in-line engine was trimmer and lent itself to a more streamlined configuration as in the F-51. The radial engine was lighter per horsepower and more powerful, but had a greater frontal area as in the F-47. The in-line engine required a liquid coolant which added weight and made it much more vulnerable to enemy fire. Although this controversy was still being waged at the beginning of World War II, most American fighters and all bombers and transport planes were designed for the radial engine.



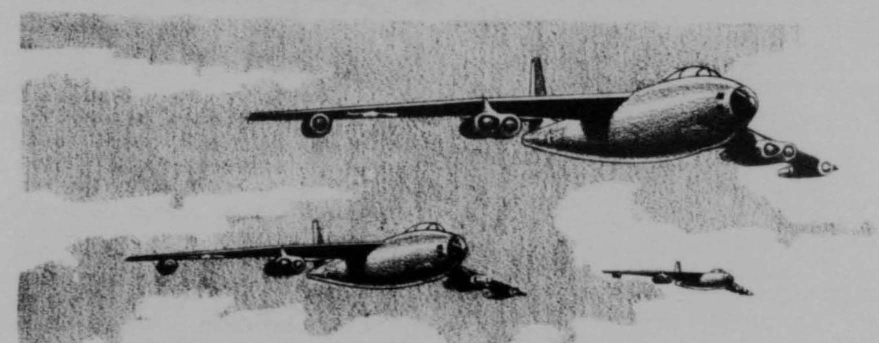
Meanwhile, a new engine was being developed. On January 16, 1930, Air Commodore Frank Whittle of the RAF filed an application for his first jet-propelled engine patent. The principle of jet propulsion was not new; in fact it is over 2,000 years old. But even by 1941 the gas-turbine jet engine was as novel as the reciprocating engine had been in 1910. The gas turbine finally had provided a power plant which the air weapon had always needed.

During the late 1930's and early 1940's, various authorities were quoted as saying that the limit of aircraft speeds had been reached. Many stated that 600 miles per hour would never be exceeded and most of them "proved" that no aircraft or human being could ever exceed the speed of sound. Today, no real authority would attempt to set even theoretical limits on the speed of aircraft. This is an amazing commentary upon the potential of the jet power plant. The X-1, a rocket-propelled aircraft carrying a pilot, has already exceeded the speed of sound.

In light of these developments, it is safe to say that the air weapon has come of age. The attainment of any desired speed is no longer an unpredictable problem. The attainment of a desired maximum range is still not entirely solved; however, piston-driven aircraft in current use are capable of ranges up to 10,000 miles. Jet aircraft have remained aloft for over nine hours and more efficient engines and new fuels will increase their range. Meanwhile, progress is being made in the field of nuclear energy for aircraft propulsion.

The situation is now reversed. The power plant has outdistanced the airframe. Aircraft manufacturers are doing their utmost to stay abreast of engine developments. Never were so many designs being tested. Today, aircraft size is no deterrent to speed. Already planes the size of the B-29 have flown as fast as all but a few of the more radical fighters. Bombers with speeds of 700 miles per hour are no longer limited to the drafting board and such aircraft are being flight tested daily.

SECTION II - TYPES OF MILITARY AIRCRAFT



1. BOMBERS

The bomber is the principal weapon of air power. It packs the punch. Until the advent of the jet engine, the bomber was looked upon as a relatively slow craft which needed to carry a considerable amount of firepower to defend itself. It also depended on strong fighter support, and in some cases, had to operate at night for protection.

Today, jet bombers are sleek, highspeed planes, in some instances as fast as the fighters which might accompany them. The great power of the jet engine has moved the bomber into the high speed class.

During the war several types of aircraft were modified for uses other than that for which they were designed. For example, the P-51 fighter was equipped to carry bombs in external wing racks and used as a dive bomber. It was then called the A-36. Today, there are three basic types of bombers: light, medium, and heavy.

Light Bombers

The light bomber has taken the place of the old attack plane. It is light, has a relatively high speed, and is powered with two engines. It operates tactically with about a 400 to 500 mile radius of action. In addition to a bomb load carried in the bomb bay, these planes may carry rockets and are equipped with machine guns for their own protection. Some models can be fitted with a nose section in which are installed eight 50 caliber guns, or possibly cannon, and are used for strafing.

Medium Bombers

Medium bombers are planes in the B-50 class with an effective radius up to 1,500 miles. This may be extended somewhat. In general, the medium bomber is not a long range type. Most tactical missions and a great proportion of strategic missions fall within its radius of action. Some of the newer types, the B-45, B-46, B-47, (all jets), will have very high speeds but rather short ranges. However, the range of jet bombers can be expected to increase with the development of new engines and fuels. Although the medium bomber carries heavy fire power for its own protection, it is, nevertheless, dependent upon fighter protection for deep, daylight penetration of enemy territory. The top bomb load in this class is about ten tons, although it varies considerably with the aircraft as well as the mission to be flown. The medium bomber is perhaps the most versatile of the bombers. It is the general purpose weapon of an air force. It is equipped for all-weather operations, radar bombing, and in some cases, may extend its range by mid-air refueling.

Heavy Bombers

The heavy bomber is the backbone of the Air Force, the weapon with which the strategic concept of air power is implemented. It is designed with the greatest possible range and bomb-carrying capacity. It contains extremely heavy fire power for its own protection, and in some cases, may even carry its own parasite fighters.

Incorporating all of the latest all-weather flying and bombing equipment, the heavy bomber is a veritable flying electronics laboratory. At the present time, the heavy bomber in operational use in the Air Force is the B-36. Powered by six reciprocating engines, with 4-auxiliary jet engines, the B-36 has proven its ability to carry a large load a great distance. Just recently a B-36 flew 9,600 miles with 10,000 lbs. of bombs.

During the early days of World War II, there was controversy over the type of heavy bombardment aircraft the Air Force should employ. One school of thought, backed largely by the example of the RAF, called for a medium range, large-capacity aircraft. Since it was planned that the bomber would be protected by a large fighter escort, defensive armament was kept to a minimum. This school of thought, considering the bomber as mainly a cargo carrier, had some validity, particularly for the RAF since their prospective targets would be within fighter range. Also, it was planned to attack at night for further protection.

The other school of thought considered the heavy bomber to be something of an aerial battleship. It was to be able to fly long missions without fighter cover, and capable of defending itself with its own armament. This was the American view. It proved successful because early in the war, bases in France were lost, leaving England as the only base of operation. This put most of the targets in Germany beyond the range of protecting fighters. The RAF, with its heavy bombers lacking protective fire power, operated under cover of darkness while the USAAF, with its B-17's and B-24's heavily armed, was able to reach into industrial Germany in daylight.

In the Pacific, this choice of a heavily-defended, long-range bomber was particularly advantageous because the great distances and the small supply of escort fighters left the protection of the bomber formation up to itself. When the B-29 became operational, it became at once the best self-defended aircraft in the world. It carried tremendous fire power; furthermore, groups of guns could be operated remotely by one gunner.

Looking into the future, one finds that the general characteristics desired of our heavy

Figure 1-1 U. S. Air Force Bomber Aircraft

bombers may be set down with little trouble.

In regard to range, the radius needed to hit the majority of the targets offered by our potential enemies is about 4,000 nautical miles, if operations are to be conducted from our present outlying bases in Alaska, Newfoundland, and Greenland. If operations are to originate from the United States, the minimum radius needed is about 5,000 nautical miles. Even then, it may be necessary to resort to range extension by refueling on vital targets.

The speed obviously should be as high as possible since speed in itself is some protection against all forms of opposition. The degree of protection is, of course, proportionate to the speed which can be attained.

The bomb load should be as high as possible because conventional bombs undoubtedly will be used on certain targets to avoid the tactical as well as the economic and political complications that might result from the use of the atomic bomb. The minimum satisfactory bomb load should be one atomic bomb.

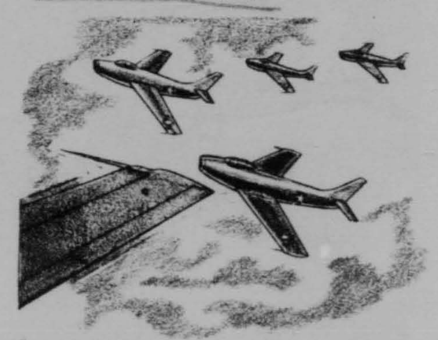
Ability to hit the target under any conditions of visibility must equal that of visual bombing. This is as important with the atomic bomb as with any other, even considering the relatively high destructive capacity of this bomb. The fact still remains that strategic bombers must be capable of hitting specific targets, as well as general areas.

Effective means are needed to counteract radar-controlled night fighters and antiaircraft guns. There is every reason to believe that the night fighter of the future will be a highly potent weapon, even though it probably will not approach the effectiveness of the day fighter for some time to come. The threat of the night fighter must, therefore, be recognized and the bomber must be equipped with an adequate defense against this type of attack. Failure to do so might well mean excessive losses. It will be necessary to minimize the effectiveness of radar-controlled flak by jamming or some other yet to be developed method.

Precision, all-weather navigation will be a necessity. Long range operations will present some very difficult problems in navigation because of weather, long overwater flights, unfamiliar terrain, flights over polar areas, and other factors. Our bombers, therefore, should be equipped with all the feasible devices available for quick and accurate position plotting. These devices should include radar, radio, automatic position plotting, rapid celestial observation equipment, and any other helpful device that may be developed. This is important in assuring that the aircraft reaches the target and returns.

The requirement for all-weather aircraft is obvious and necessary. Bomber development virtually has reached that point now.

Whatever the details may be, it is certain that the bomber of the future will have a very high speed; it will be well armed; it will be capable of carrying the atom bomb; and it will probably be able to reach any target of importance in the Northern Hemisphere from home bases.



2. FIGHTERS

The fighter is a highly specialized aircraft. As its name indicates, it is designed for one mission—to engage the enemy in the air. This does not mean that the acrobatics of World War I, or the sweeps of World War II, will be the methods employed. The high speed of the modern fighter will dictate that it hit hard, accurately, and once.

Interceptor

The interceptor is a more specialized type of fighter. It must be capable of getting into the air and up to operational altitude in a very short time. It will not be required to fly long or far, so it will not need a large fuel capacity. It will be home-based, and will be

GCA - Ground Control Approach

RESTRICTED

used predominantly against enemy bombers. Its armament is undergoing revision from the standard 50 caliber machine guns of World War II. Because of the high rate of closure between the modern interceptor and its target, the time of effective fire is extremely brief. Therefore, the rate of fire of the machine gun must be increased. Attempts are being made to arm the interceptor with rockets to increase its fire power and effectiveness. These rockets would presumably contain proximity fuses and it is hoped that they will incorporate some homing device which will guide them to the target. While the armament designers are working on these problems, the aircraft engineers are faced with the problem of removing every unnecessary bump, corner, or other protuberance which produces drag on the aircraft. Guns and rockets necessarily do this, so attempts are being made to shield or streamline them as much as possible.

All-weather Fighter. The all-weather fighter is a fighter equipped with electronic apparatus which will enable it to detect and destroy the enemy at night and under adverse weather conditions. At present, the F-82 is the standard all-weather fighter.

Escort Fighter. The primary difference between the escort fighter and the interceptor is the long range of the escort fighter which enables it to accompany bombers on long range missions. Not long ago, an F-82 flew nonstop from Hawaii to New York, a distance of close to 5,000 miles. With the jet fighters currently available, this distance could not be equaled. However, one jet fighter, the F-85, has been designed to fit into the bomb bay of a large bomber. It could be carried by the mother ship into the combat zone and there released for operational use. The parasite fighter can be recovered in flight and returned to the bomb bay of the carrier plane. Some such system may well be the answer to the problem of fighter range extension. Towing and mid-air refueling also are being tested.

During the later stages of World War II, the escort fighters actually covered the entire route of the bombers and are credited with a good share of the success of the long range, daylight missions of the Air Force. Their psychological effect was another factor. It was said that when Goering saw American fighters over Berlin he admitted that the war was all but over. Likewise, fighters over Japan had a demoralizing effect on that country.

There is a good possibility that fighters will continue to be of several specialized types, but they will all have certain requirements which must be met.

Speed is the fighters greatest asset. The newest fighters are now pushing at the sonic barrier. The X-1 has already exceeded the speed of sound in test flights. The F-86, F-88, and F-89 also can be expected to exceed the speed of sound and present indications are that the quest for more speed in fighters will continue.

The range of which the fighter must be capable will depend upon the primary use for which it is intended. Whenever any airplane has its load increased, the speed and the rate of climb suffer; therefore, any increase in the range capabilities of a fighter are made at the expense of its speed. However, the fighter must, in general, have enough fuel to get it to the target and return and to fight at the target a sufficient time to be effective. It now appears that any strategic escort fighter should have a radius of action of at least 2,000 miles or be capable of being towed or carried with the bomber force.

Firepower on a fighter must be heavy enough to bring the enemy bomber or fighter down or to damage it severely in the shortest possible time. The use of armor makes it necessary that the weapons used be capable of penetrating and damaging the unarmored part of the enemy plane to such an extent it will be destroyed or at least rendered ineffective.

Ability or means to hit the target is a must for the fighter. There should be an automatic range and deflection calculator which will work with minimum help from the pilot. In the high speed fighter, little time will be available for sighting and firing. It must be used to good advantage.

That the fighter must be maneuverable needs little elaboration. Pilot blackout must be postponed as long as possible. Maneuver-

THIS PAGE IS DECLASSIFIED IAW EO 13526

Figure 1-2 U. S. Air Force Fighter Aircraft

ability must be as good or better than that of the defending interceptors.

3. TRANSPORTS AND GLIDERS

Another type of military aircraft is the transport plane. This type is usually designed for a specific purpose. The very large transports of the C-99 class will be used for long hauls with vital loads. They will be indispensable in areas where water transport is too slow or impossible. Much of the equipment of the Army today is being designed with a view toward air-transportability. For troop movements, transports need not be very large. Because it is to be expected that many troop transports will be required to land in forward areas upon small and undeveloped bases, several medium transports have been designed specifically for that type of operation. The C-119 "Packet" is a fine example of a troop and cargo carrier. Recently, this plane was equipped with track-type landing gear to enable it to operate from undeveloped fields. Another version of the C-119 is being constructed with a detachable "pod" for a fuselage. A fully-loaded "pod" could be attached to the air frame and flown to a given area. There it could be detached quickly and another fully loaded "pod" could be flown back.

Transport aircraft, generally, are sturdy, reliable types, built for their carrying capacity. They are not as fast as other types and are generally not armed. Many cargo plane manufacturers are looking to the jet propulsion field for greater speed and power.

To augment the transports, gliders were used extensively during World War II. They usually are built along strictly utilitarian lines. These may in the future be supplanted by small transports which may be used over and over again. Gliders in actual operations usually make a one way trip.

4. TRAINERS

Training planes are those developed specifically for flight school purposes. All types of aircraft are used extensively for training of one kind or another, but the trainer is used mainly in the flying schools.

The modern primary trainer is the first aircraft the fledgling pilot flies. It is a very airworthy, nearly fool-proof type, but built with many of the controls, instruments and equipment which are found in the combat planes. When the student becomes proficient in the primary trainer he is ready to fly the advanced trainer.

The advanced trainer may or may not be a special training type. Ordinarily, the student progresses from the primary trainer to the advanced trainer and is classified either as a bomber pilot or as a fighter pilot. The advanced single engine trainer is designed to prepare the student for such planes as F-51, F-47, and jet fighters. As a matter of fact, the F-51, F-47, and TF-80 are themselves used as advanced trainers in the last stages of training. The advanced twin engine trainer is designed to prepare the student for any multiengine aircraft.

5. MISCELLANEOUS AIRCRAFT

In addition to the major types of planes described above, there are many more types available for Air Force use. Some of these are planes used for purposes other than that for which they were designed. Others are engineered for specific missions.

The aircraft used for air-rescue work for example, are, with two exceptions, conventional bombing planes so modified as to enable them to drop lifeboats to personnel in the water. The amphibian is a specially developed aircraft particularly helpful in air-rescue work since it can operate from either land or water. The helicopter is becoming increasingly important in both air-rescue and liaison operations. It is able to land and take off in very small areas, and it can pick up personnel from otherwise inaccessible places.

Reconnaissance and photographic aircraft played an important part in the past war. When the first airplanes were delivered to the Army they were considered to be the eyes of the ground troops. Today, they are still the eyes of the armed forces, but the reconnaissance mission has broadened considerably. Tactical reconnaissance takes place in the combat zone, while strategic reconnaissance is carried deep into enemy territory. Much of the reconnaissance of today is photographic and aerial mapping.

Probably every combat aircraft of the Air Force has at one time or another served as a

Figure 1-3 U. S. Air Force Cargo Aircraft

Figure 1-4 New and Experimental USAF Aircraft

THIS PAGE IS DECLASSIFIED IAW EO 13526

reconnaissance or photographic plane. With one exception, no airplane has been developed by the Air Force for the specific purpose of reconnaissance. The planes have been basic types, stripped of all armor and armament, with cameras installed. They are dependent upon superior speed for protection. The one exception is the "Rainbow", a four-engine aircraft designed for high-speed, high-altitude, photographic reconnaissance. Just recently, this plane flew from California to New York making a strip map as it flew. It took a continuous picture of its flight path all the way across the United States from an altitude of about 40,000 feet.

Ordinarily special aircraft are not built solely for experimental and service test functions. However, at times it becomes necessary to test some new design or power plant with an experimental model. Today, the Air Force classifies these planes with the designation "X", signifying those purely for experimental purposes. The X-1 is the best known of this type. It was designed to explore the speed range around the speed of sound. From lessons learned with this plane, future aircraft can be constructed directly as operational types. Some new models are not experimental. They have been tested but not yet accepted for operational use. These are classified as service test aircraft. The classification does not cover any particular type as all new aircraft designs go through the service test stage before being accepted.

A drone is any conventional aircraft modified to be flown by remote control without a crew aboard. During the Bikini atom bomb tests, drone aircraft flew through the radioactive cloud taking pictures and samples of the air above the blast. Later three of these drone B-17's flew, in formation, from Hawaii to Muroc, California, to demonstrate the capabilities of radio controlled aircraft. Drone fighters, F-80's, have been tested with the object in mind of using a similar system of remote control in fighter action.

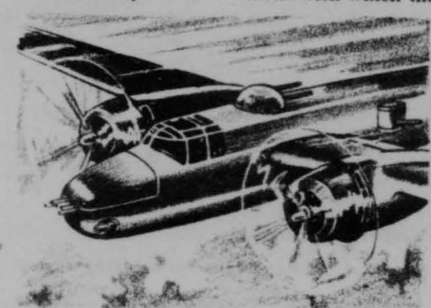
SECTION III - DESIGNATION OF USAF AIRCRAFT

The particular tactical and operational employment of an airplane determines its USAF classification. By "tactical and operational employment" is meant its use for bombardment, training, etc. When an airplane performs more than one function, the secondary function is designated by the first letter and the primary function by the second letter, e.g., an F-80 fighter used as a trainer would be designated TF-80. If the same fighter were used as a reconnaissance plane it would be designated a RF-80. The model of a particular classification is designated by a number, e.g., B-29. Furthermore, there may be a series of a particular model on which minor modifications have been made. Such a series is designated by a letter following the model number, e.g., B-29B.

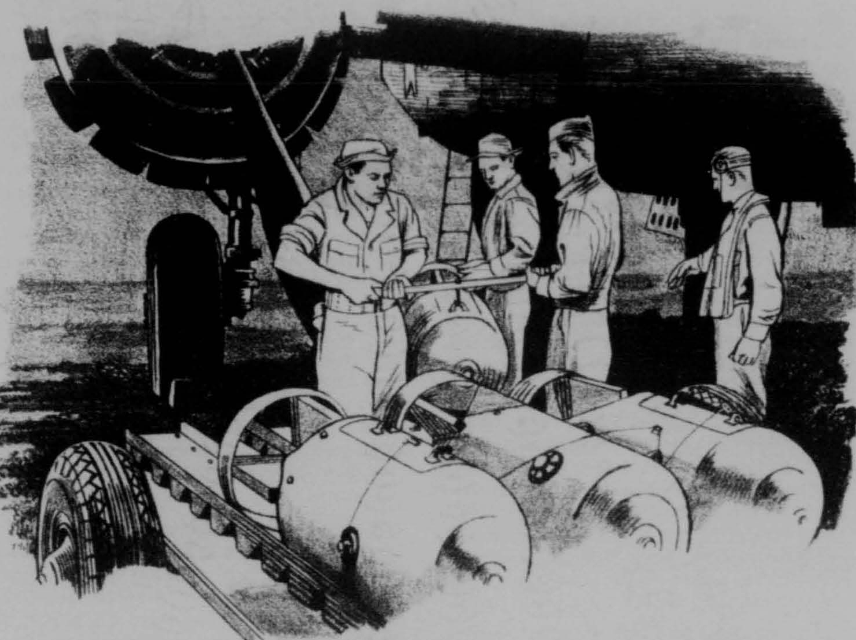
A few USAF aircraft designations are set forth in the following list:

Bombardment	B	(B-36)
Cargo	C	(C-54)
Fighter	F	(F-86)
Rotary Wing	R	(R-5)
Trainer	T	(T-6)

So much for the airplanes themselves. The next chapter will deal with some of the equipment with which these aircraft fight.



CHAPTER 2 - AIRCRAFT FIGHTING EQUIPMENT



SECTION I - RADAR

1. RADAR PRINCIPLES

Radar—Radio Detection and Ranging—is one of the great scientific developments of World War II. Its development, like the development of many other great inventions, was mothered by necessity—namely, the necessity for offsetting the offensive power of the airplane. It was in the detection of ships and aircraft that radar found its first usefulness.

Radar is, by definition, an application of radio principles by means of which it is possible to detect the presence of objects in space. The principle upon which radar operates is very similar to the principle of sound wave reflection. If a person shouts toward a cliff, or some other sound-reflecting surface, he hears his shout return from the direction of the cliff. In other words, he receives an echo. What actually takes place is that the sound waves generated by the shout travel through the air until they strike the cliff. Some of the reflected waves return to the original spot, where the person hears the echo. Some time elapses between the instant when he shouts and when he hears the echo, since sound waves travel through the air at approximately 1,100 feet per second. With suitable devices, it is possible to measure the distance and di-

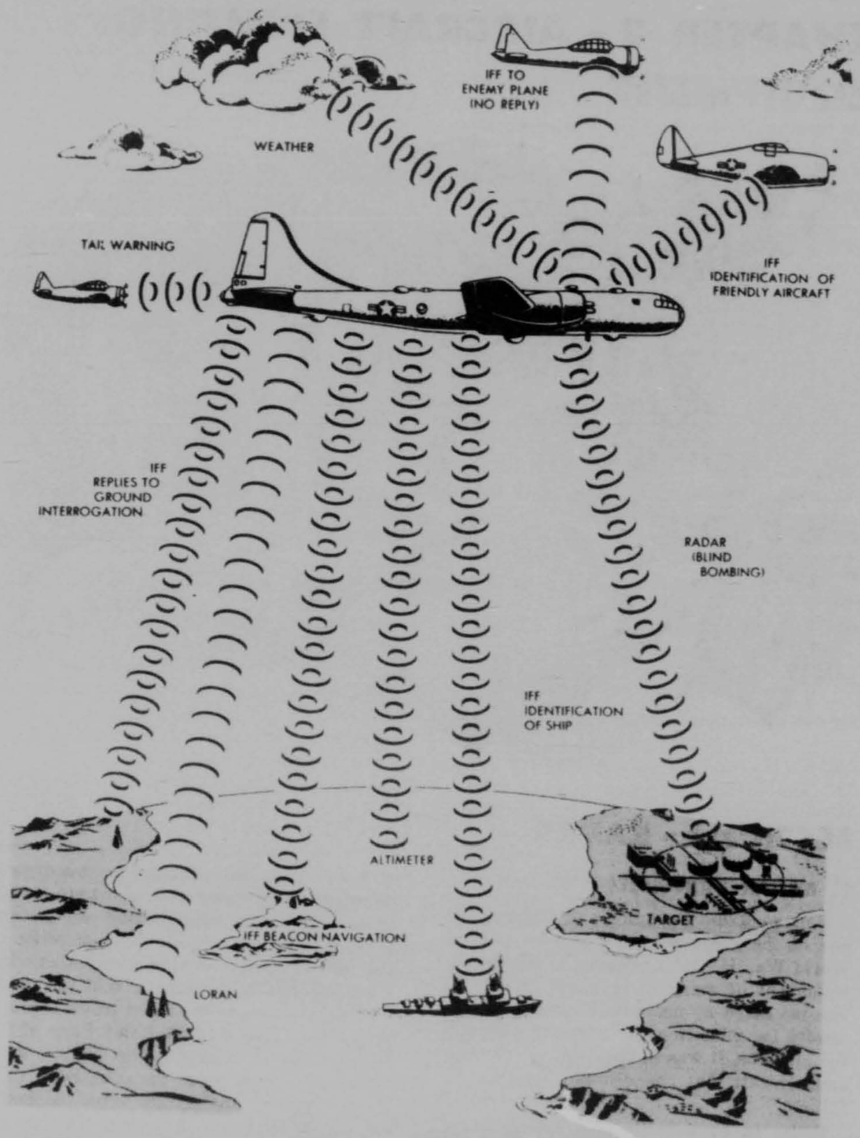


Figure 2-1 Aircraft Radar Aids

rection of the cliff from the person as well as the height of the cliff.

All radar sets work on a principle very much like that described for sound waves. In radar sets, however, a radio wave of extremely high frequency is used instead of a sound wave. The energy sent out by a radar set is similar to that sent out by an ordinary radio transmitter. The radar set, however, has one outstanding difference in that it picks up its own signals. It transmits a short pulse and receives its echoes, then transmits another pulse and receives its echoes. This out and back cycle is repeated from 60 to 4,000 times per second depending upon the design of the set. If the outgoing wave hits no object in space it simply travels on out into space and is not reflected.

If, however, the wave strikes an object such as an airplane, a ship, a building, a hill, or a cloud some of the energy is returned as a reflected wave. If the object is a good conductor of electricity or is large, a strong echo will result. If the object is a poor conductor or is small, the reflected energy is small and the echo is weak.

Radio waves of extremely high frequency travel in straight lines at a speed of approximately 186,000 miles per second. Thus, there will be an extremely short time between the sending of the pulse and the reception of its echo. It is possible to measure the interval of elapsed time between the transmitted and received pulse with great accuracy — even to one ten-millionth of a second.

The directional antennas employed by radar equipment transmit and receive the energy in a more or less sharply defined beam. Therefore, when a signal is picked up, the antenna can be rotated until the received signal is of maximum intensity. The direction of the object or target is then determined by means of the position of the antenna. The echoes received by the radar receiver appear as marks of light on a specially-constructed instrument called an oscilloscope, or scope for short. This device measures the time required for the radio energy to travel out to the target and return. It usually is calibrated in miles so that the range to the target may be read directly off the scope.

2. RADAR TYPES

The discussion of the types of radar sets that have been developed for specific uses will be in general terms.

If the Air Force is to accomplish its mission on an around-the-clock and all-weather basis, equipment is needed to make such operations effective. There must be navigation devices which make possible precision navigation during instrument flight conditions when neither ground observations nor celestial observations can be obtained. There must be a device to permit accurate bombing of targets when smoke, haze, clouds, or dust obscures the target. There must be warning and identification devices to warn an aircraft of the approach of another aircraft and to identify it. And lastly, there must be a system to aid aircraft in landing at bases when ceiling and visibility are below safe landing conditions.

The navigational and bombing requirements were met by the use of essentially the same type of radar sets. In order that the airborne radar set could be used for navigational purposes, it was necessary to display the received signals in some way that would be useful to the operator. Basically, the chosen method for displaying the received signals was a Plan Position Indicator (PPI) scope. This scope shows the signals as spots or "pips" of light on the face of the scope. The resulting target display then shows the relationship of the targets radially for relative bearing, and by measuring their distance from the center of the scope the range to the target can be determined. (Figure 2-2) To solve the radar bombing problem, a method called "radar synchronous bombing" was developed. This method employs a computer into which necessary bomb release information is set. The computer also has a driving mechanism similar to that of the Norden bomb sight. With this computer, the radar operator synchronizes the rate of the drive mechanism with the rate of closure on the target. The bomb release time is determined by the computer and the bombs are released automatically. This bombing-device is used in conjunction with the type of navigational radar set described above.

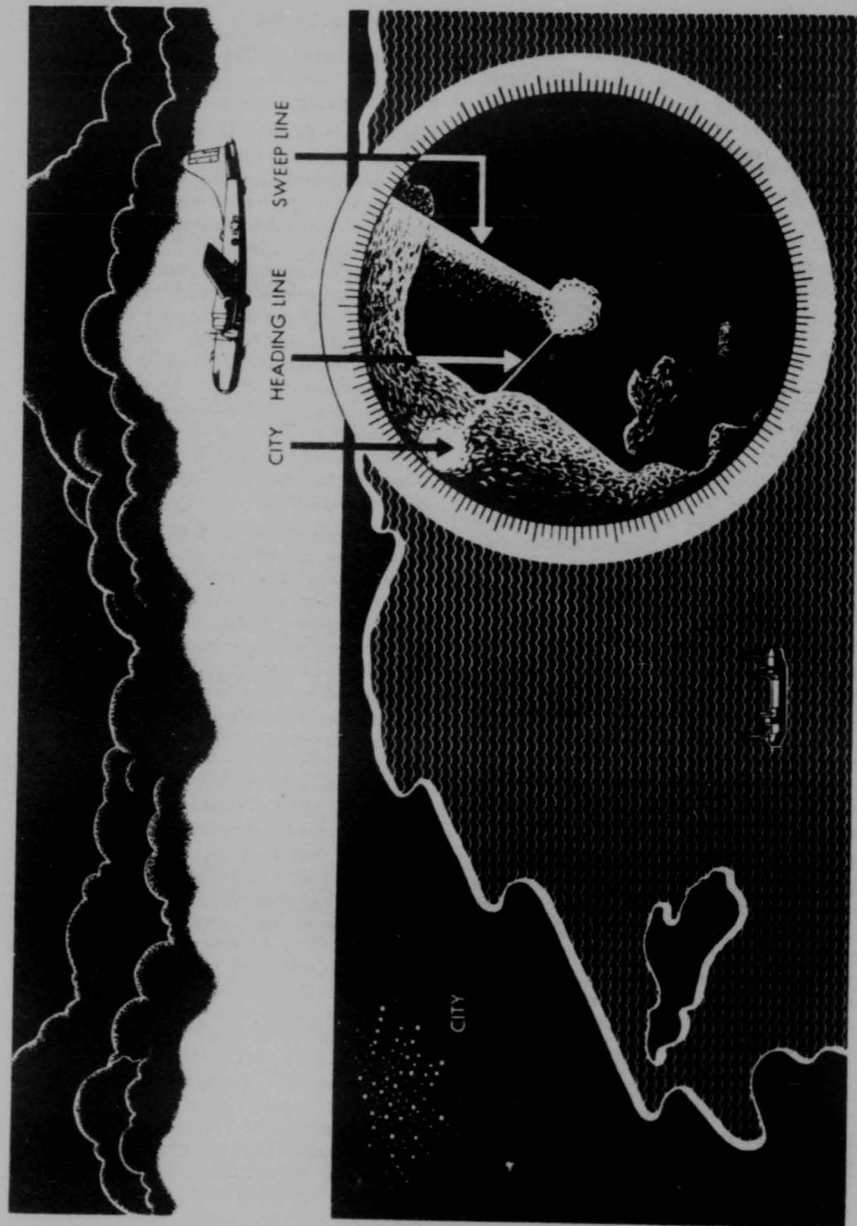

Figure 2-2 Radar Navigation

Another type of navigation and bombing radar is the Short Range Navigation (Shoran) system. It can be used for either navigation or bombing or both. The system employs the use of two ground beacons and an airborne radar set designed to trigger those beacons. It then measures the elapsed time between the transmission from the airborne set and the reception of the beacon signals. Since the exact geographical position of the two ground stations is known, the position of the aircraft can be determined with great accuracy. As the name implies, the system can be used for short range work only. A similar system, Loran, is used for long range navigation.

When using Shoran for bombing, the bombing problem is solved in terms of the distance of the bomb release point from each of the beacons. The release point is determined prior to the mission and the distance from each beacon is measured to the nearest one-hundredth of a mile. These distances are pre-set into the computer and the aircraft makes the bomb-run with one beacon being used to determine course and the other to control the bomb release.

Tail-warning radar is used to give indication of another aircraft approaching from the rear. The signal is transmitted from the first aircraft and reflected from the aircraft in the rear. Returning to the receiver, this reflected signal activates both a buzzer and a light on the instrument panel as a warning to the pilot.

The IFF (Identification-Friend or Foe) set was used extensively during the past war to identify aircraft to ground radar stations. A ground transmitter sends a signal to a receiver in the aircraft. When the signal is received it activates a transmitter in the aircraft which automatically sends a coded signal to the ground station.

The all-weather fighter depends upon radar to accomplish its mission. The many different radar sets in the aircraft enable it to search for and find its target, automatically compute the range and fire the guns without ever seeing the enemy aircraft.

All of the airborne radar equipment would be of little value to an all-weather air force if there were no provision for landing the returning plane in bad weather. A method by which this may be accomplished is the ground radar system called Ground Control Approach (GCA). The GCA system provides facilities for directing the movement of aircraft in the vicinity of an airdrome and over a predetermined glidepath for a safe approach to the proper runway under conditions of adverse visibility. Accurate and continuous information regarding the location of the incoming aircraft is presented to the ground operators in the form of range, azimuth, and elevation data by the radar portion of the system. This information is interpreted by the operators as lateral and verticle deviations from the glidepath. It is communicated to the pilot by radio in the form of instructions regarding the course he must fly in order to make a safe approach to the runway.

These are but a few of the radar systems that are used both in aircraft and in ground control of aircraft. However, they will suffice to give a general background of the types and capabilities of radar sets.

SECTION II - GUNS AND ROCKETS

1. GUNS

The primary weapon with which USAF aircraft is equipped is the 50 caliber air-cooled machine gun. It may be mounted in fixed positions and fired by the pilot as in the fighter, or it may be mounted in turrets and fired by individual gunners as in the bomber. The trend in the latter is toward central fire control, where a number of turrets may be fired by a gunner whose sighting position is remote from the turrets themselves. The rate of fire of the 50 caliber machine gun is about 1,000 rounds per minute. With the greatly increased speeds of the modern aircraft resulting in an extremely high rate of closure between fighter and bomber and an extremely short time for aiming and firing, steps are being taken to increase the rate of fire.

As to future trends in aerial gunnery, we find that while turrets, guns, and radar computer combinations are fairly accurate at ranges closer than a thousand yards, the rate of closure increases the errors of operation in direct ratio to the distance involved. Because of these errors and limitations in equipment, attention has been concentrated upon: a) heavier guns having longer ranges; b) improvements in automatic radar ranging and firing devices; c) improvements in electronic ballistic computers (for use with radar gun equipment); d) a heavier concentration of fire power for aircraft having defensive weapons, i.e., all plans for heavy bombers call for nothing less than 20 millimeter cannon; e) improvements in remote control turrets.

All these developments indicate that most major designers are working on the basic premise that as supersonic speeds are more closely approached, the human element is less capable of dealing with the increasingly complex problems of aerial gunnery.

2. AIRCRAFT ROCKETS

It is hoped that the problem of gunnery at supersonic speeds may be solved, in part, by the substitution of the aircraft rocket for the caliber 50 machine gun. The military use of present-day rockets is well known. Aircraft rockets have the same effective action as projectiles from 155 millimeter guns and are most useful against military targets such as locomotives, tanks, vehicles, buildings, boats, gun emplacements, and harbor installations as well as against enemy aircraft both in the air and on the ground.

The use of aircraft rockets has expanded at an incredible rate. In 1945, the Navy alone was spending as much as $100,000 a month for rocket ammunition. The use of rockets became axiomatic for amphibious landings after just a few trials. The reason for this sudden expansion was due to the fundamental advantages of the rocket over artillery.

In the airplane, the aircraft rocket has far greater range than the heaviest gun that aircraft could carry without major modifications. The trajectory is flatter for aircraft rockets than ground rockets because the speed of the plane is added to the initial velocity of the rocket. Consequently, the accuracy is exceptionally good. It was found that aircraft rockets fly straight to the target instead of following a curved trajectory like that of ground rockets. The principle of reaction, by which rockets are impelled forward, brings about a third definite advantage, namely lack of recoil of the mount or of the launcher. Thus, there is little of the shock of firing acting upon the airplane so that very light launching apparatus may be used. As a direct result the load and strain on the airplane is much less than if a heavy gun mount had to be carried. Although, at present, only a few sizes of rockets are in use, a wide range of rocket sizes is feasible for aircraft. The gentle take off allows high powered, but more sensitive, explosives to be used in the rockets.

The principal rocket used today by aircraft is the 5.0" high velocity aircraft rocket (HVAR) which is launched from racks under the plane's wings.

SECTION III - BOMBS

1. GENERAL

At the end of World War I, the world realized to some extent the value and importance of the airplane and the high explosive bomb as an offensive weapon. During the years following the war, there was great activity in bomb and bomb fuze development as well as in the field of bomb ballistics. When bombs were first used, they were suspended

vertically, nose down in a rack. It was soon discovered that this was not the correct position and that a bomb must be started off in a horizontal position tangent to its true trajectory. The lifting power of the aircraft increased and so did the size of bombs—from 600 lbs. to 4,000 lbs. in two years. Careful studies were made in the tactical use of bombs to determine the economical limits for the sizes of bombs. It was decided that there should be three types: fragmentation bombs, chemical bombs and demolition bombs.

2. CONVENTIONAL BOMBS

General Purpose Bombs

General purpose bombs are designed to meet the requirements of the great majority of bombing missions. The various models range from 100 to 4,000 lbs., and the percentages of explosive in this type averages 50 per cent of the loaded weight of the bomb. General purpose bombs may be used for blast, fragmentation or mining effect.

Light Case Bombs

The light-case, 4,000 lb. bomb is highly effective as a blast bomb for targets requiring no penetration. It must be fuzed to explode before the case breaks up on impact and, therefore, should be employed only on those targets against which surface blast is effective. In other respects this type of bomb resembles the general purpose bomb described above.

Armor-piercing Bombs

This bomb is designed to pierce the heavy deck armor of modern naval vessels. The case is extremely heavy and, to be effective, the bomb must score a direct hit. The effect of a near miss is comparatively minor because of the small amount of explosive in the bomb. This type should not be used against unarmored or lightly armored ships because, being fuzed with delay fuzes to permit penetration, the bomb would pass right through a light vessel.

Semiarmor-piercing Bombs

These bombs are essentially the same as the general purpose, except that the case is heavier and the explosive charge is less. This type is good for lightly-armored targets.

Depth Bombs

The depth bomb is a light case bomb containing 79 per cent of its weight in explosive. It is designed for use against submarines and is fuzed with a hydrostatic fuze which functions at a predetermined depth rather than upon impact.

Fragmentation Bombs

Fragmentation bombs are designed to produce their effect through projection of the fragments of the case, and are intended for use against personnel and light material. When employed in sufficient numbers to cover large areas, either from high altitude in clusters or from minimum altitude with parachutes, fragmentation bombs will effectively damage light material targets such as radar equipment, aircraft, vehicles, antiaircraft guns, light artillery, etc., and will produce extensive casualties among exposed personnel.

Chemical Bombs

Chemical bombs are of two types: those containing gas or smoke, and those containing inflammable material such as oil, napalm, or magnesium. They have a variety of uses, ranging from the use of smoke to conceal activity from the enemy to the use of incendiaries to burn targets.

3. ATOMIC BOMBS

The advent of the atomic bomb has put into the hands of air power the most destructive weapon man has ever known. In the explosion of an atomic bomb, matter is transformed into energy by nuclear fission. This energy, which is released, is of such magnitude and from so concentrated a source that it sets up entirely new problems in its use and in protection against it. The energy takes three forms, and all effects of the bomb can be attributed directly to the three. They are: 1) heat (similar to flash burns but greatly intensified); 2) radiation (similar to X-rays or to that from radium); 3) blast (as from a demolition bomb).

To compare the e[illegible]s of the atom bomb with those of the conventional bomb, data obtained from the atomic bombing of Nagasaki may be used. At that target, the blast effects of the bomb were on a new scale because the duration of the blast was long compared to that of a high explosive bomb. To take only one example: At Nagasaki, brick buildings suffered structural damage within a radius averaging 6,000 ft. from the impact point. Comparable damage would have been done by a 500 lb. high explosive bomb for a radius of 55 ft.; by a 1,000 lb. bomb for 80 ft.; by a 2,000 lb. bomb for 110 ft., and by a 4,000 lb. bomb for 200 ft. The area of effectiveness of the air burst of the atomic bomb against brick buildings thus was 15,000 times as great as that for a 500 lb. conventional bomb.

As for the casualties resulting from the atomic bomb, a comparison is afforded between Hiroshima and Tokyo. At Hiroshima, one B-29 carrying one atomic bomb caused 70,000 to 80,000 to be killed or missing. At Tokyo, in one raid 279 B-29's carrying 1,667 tons of bombs caused 83,000 to be killed or missing. The United States Strategic Bombing Survey pamphlet, "The Effects of Atomic Bombs on Hiroshima and Nagasaki," estimates that, based upon results obtained at those two targets, in order to equal the effectiveness of one B-29 with one atomic bomb, an attack with conventional high explosive bombs would have to be carried out by a total of from 210 to 270 B-29s each carrying ten tons of bombs.

No one is certain what the future holds in the way of the employment of the atomic bomb. General Spaatz wrote the following in Life magazine: "More than 40,000 people were killed in the British attacks upon Hamburg in July and August, 1943. In the great March, 1945, attack on Tokyo, 125,000 people perished and 75,000 more were rendered homeless in a single night by some 3,000 men in only 279 airplanes. Three attacks within fifteen hours wiped out Dresden and buried perhaps 60,000 in its ruins. These terrifying magnitudes of destruction were brought about by air power with only the conventional high explosive bomb.

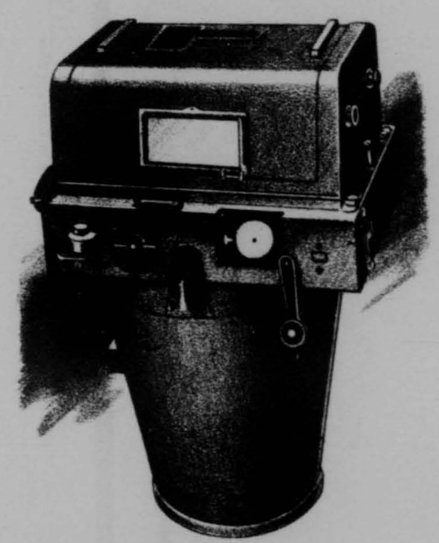
"The destructivce power of the present atomic bomb, measured by military standards, has been exaggerated by laymen. Yet the fact remains that it injects a multiplier of destruction into the effectiveness of each bomber on the order of hundreds to one. Wars that might otherwise last years may be ended in weeks, perhaps days. And campaigns that would otherwise cost the lives of hundreds of thousands of soldiers and sailors may now be the work of a few hours by a few men. Much that would have been impossible becomes possible with the atomic bomb."

SECTION IV - AERIAL CAMERAS

Knowledge of the enemy is one of the essentials of military victory. Aerial cameras and aircraft, combined with the skills of the photo interpreter, the photogrametrist, and the intelligence analysist, give the present military commander a major portion of the required knowledge. The advantages of aerial photography were recognized as far back as the Civil War. Photographers with wet plates went up in captive balloons, just behind the front lines, and took pictures of the opposing forces. Despite crude equipment and limited range the results had military value.

From these early Civil War efforts, aerial photography has evolved into an exact

science. All aerial photographs fall into two main categories: **verticals** and **obliques**. Vertical photographs are made from an aerial viewpoint with the camera axis perpendicular to the earth. Oblique photographs are made from an aerial viewpoint with the camera deflected from the perpendicular. High oblique photographs are those which show the horizon. Low oblique photographs do not show the horizon. For the many varieties of these basic types of aerial photography, specialized aerial cameras have been developed. The remaining paragraphs of this chapter are devoted to a short review of this equipment and its uses.



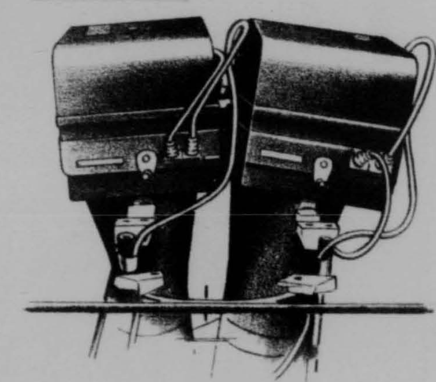
The essential parts of an aerial camera are: the lens cone, the camera body, and the film magazine. Cones vary from the 6″ with wide angle lens, to the 40″ with telephoto lens. The standard work horse in the aerial camera field is the 12″ cone. From this cone are obtained photographs whose scale is one over the altitude of the aircraft, i.e., at 10,000 feet the scale of the photograph is 1: 10,000. Controlling the entire operation of the camera is the camera body. Here are housed the winding and tripping mechanism, operated either manually or electrically; the frame, which varies from a 4″ x 5″ opening to 9″ x 18″; the film transporting assembly; and miscellaneous accessories, such as level, film counter, manual shutter release, etc. Within the magazine is housed the film. Aerial film comes in rolls whose width is either 5″, 7″, or 9″, and whose length varies from 20′ to 390′. (Figure 2-3).

Cameras shown in Figure 2-3 can be used in a variety of combinations. Some of these are:

Mapping—controlled mosaic maps, K-17 with 12″ cone, held to a maximum of 3° tip or tilt. Uncontrolled mosaics, K-3B, K-17, and K-22 with either 6″ or 12″ cone.

Tri-metrogon mapping — three K-17 cameras, with 6″ wide angle cones. One camera is vertical. The other two are the right and left obliques. Each is tilted 30° from the horizontal. Horizon to horizon photography is the result.

Pinpoints: Any vertical camera. The type depends on the military situation and the information desired.



Split-verticals: Two cameras each tilted 7° from the vertical. Normally the K-22, with 24″ cone is used for this purpose.

Hi and Lo Obliques: K-3B, K-17, and K-22 camera, with 12″ cones are tilted 15° from the horizontal for high obliques, and 30° for low obliques.

Dicing: High obliques taken from the nose of the aircraft at minimum altitude. This

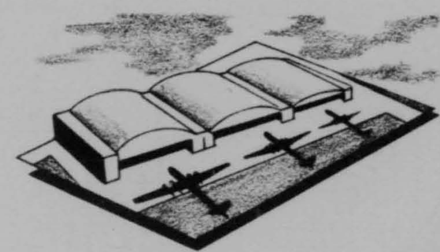
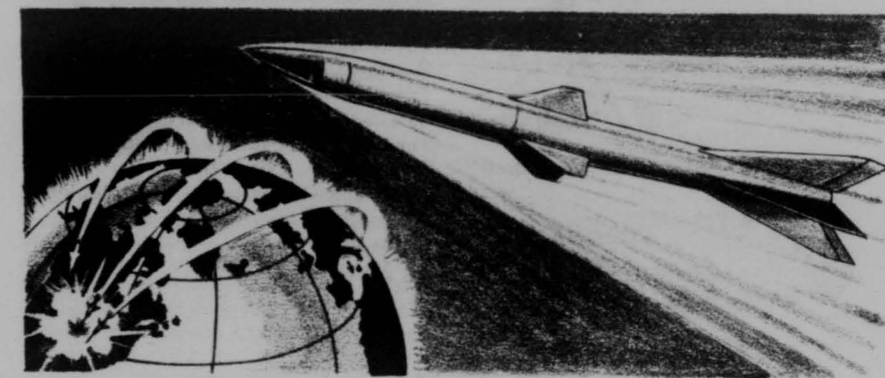
type of photography is also called a forward shooting oblique. (Figure 2-4.)

As mentioned in the introductory chapter, aerial cameras have been installed in almost every type of aircraft. Two types of photographic aircraft are currently in use. For short range, tactical reconnaisance the Air Force uses the RF80, which is a modified F-80. All cameras are carried in a specially-constructed nose section. For long range strategic reconnaissance, the Air Force uses a modified B-29. (See Figure 2-4.) This aircraft is known as the F-13.



CHAPTER 3 - GUIDED MISSILES



SECTION I - GENERAL

1. INTRODUCTION

Spurred on by the requirements of World War II and occupying an increasing portion of our military interest is the development of a new weapon—the guided missile. The guided missile presently is being considered as a supplement to the airplane, but may in the future supplant the airplane as the primary weapon of air warfare.

A guided missile is, simply, **any missile to which guidance control may be applied after it has been launched**. That is, it is an air vehicle which may be flown without a crew aboard. Note that it is any missile. This means that the term includes rockets, bombs, glide bombs, etc., as well as remote-controlled aircraft.

The only prewar development of a remotely-controlled missile that was actually flown in this country was a small aircraft controlled by radio from the ground or from another aircraft. These aircraft were used as targets for antiaircraft and aerial gunnery practice.

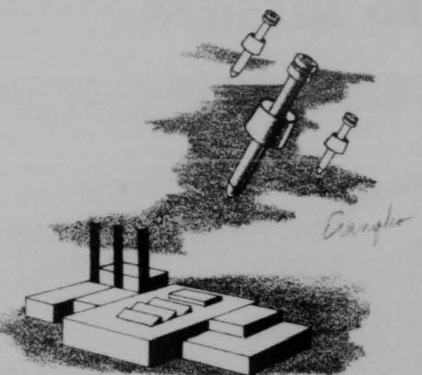
The use of guided missiles, including pilotless aircraft, as weapons was introduced effectively in World War II. The Germans used remotely-controlled bombs as well as missiles with pre-set controls for guiding them into general areas. We used bombs guided by radio and pilotless aircraft which were crashed into targets by television and radio control. These early weapons were the forerunners of others rapidly being developed into guided missiles which will travel at supersonic speeds and may be maneuvered by remote control to seek out automatically and destroy flying targets, or to bombard targets several thousand miles away.

2. DESIGNATION OF GUIDED MISSILES

Before beginning a discussion of the types of missiles, it would be best to learn the system of designating U.S. guided missiles, just as the system for designating types of USAF aircraft was learned. This system is used by the Army, Navy, and Air Force, and is applicable to all guided missiles developed by the three services.

The basic designation is a two-letter combination of the letters "A" (air), "S" (surface, or "U" (under water), in which the first letter designates the origin of the mis-

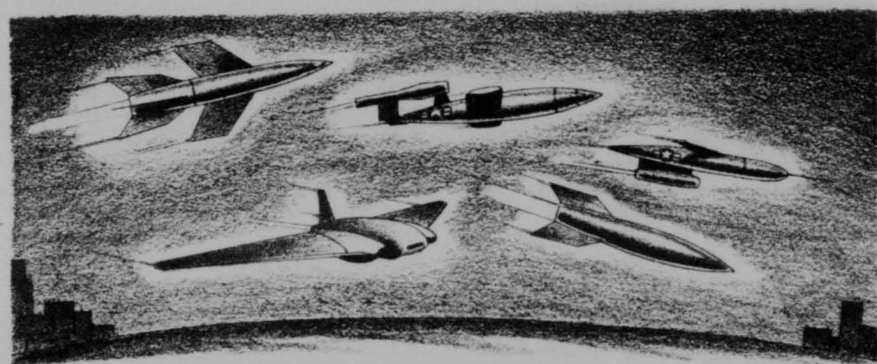
THIS PAGE IS DECLASSIFIED IAW EO 13526



sile and the second letter designates the objective. This combination of two letters is followed by the letter "M," indicating missile. Each basic designation is followed by a service letter: A (Air Force), G (Army), N (Navy); and a model number which, in turn, is followed by a modification letter, e.g., SSM-A-3b is Surface-to-Surface Missile, Air Force, Third Model, Second Modification; AUM-N-2d is Air-to-Underwater Missile, Navy, Second Model, Fourth Modification.

With proper approval a popular name may be assigned to a missile just as types of aircraft are given popular names.

SECTION II - TYPES OF GUIDED MISSILES



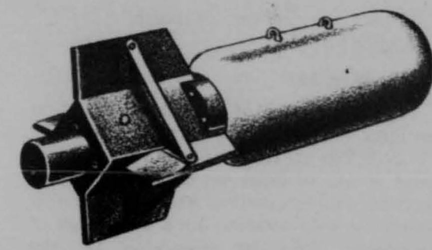
With the foregoing information as a background consideration may be given to some of the types of guided missiles developed during and subsequent to World War II. While it is neither possible nor desirable in a presentation of this nature to engage in lengthy discussion of each missile developed, it is felt that a simple description of the major types will indicate the scope of the guided missile effort.

1. UNITED STATES GUIDED MISSILES

United States missile development during the course of World War II was directed toward the successful operation of four guided missiles of the air-to-surface and surface-to-surface types. They were Azon, GB-8, Weary Willie, and Bat.

Azon

Azon is a free-falling, conventional 1,000 lb. bomb with a special tail that enables it to be steered to the left or right on receipt of radio signals from the plane dropping it. This is accomplished by a small radio receiver in the tail which activates a servo motor connected to the rudders in the bomb tail fins. Also packed in the tail are a gyro



and solenoids to change the pitch of small ailerons in the fins to prevent rolling of the bomb while in flight. The bombardier tracks the bomb by means of a flare in the tail and makes corrections in its flight by using a control box in the airplane. Azon was used quite successfully in Burma and its accuracy was estimated as being ten times greater than that of a conventional bomb against long narrow targets. It does, however, have three major drawbacks. (1) It is dependent upon clear weather because the bombardier must be able to see the bomb during its fall. (2) The altitude of release is limited to about 12,000 feet because above that altitude it becomes difficult for the bombardier to follow the bomb. (3) In order to see and control the bomb, the airplane must fly a straight and level course after release. This prevents evasive action and makes the launching plane very vulnerable.

GB-8

GB-8 is a standard 2,000 lb. bomb to which a set of twelve foot wings and control surfaces have been added, making a glide bomb.

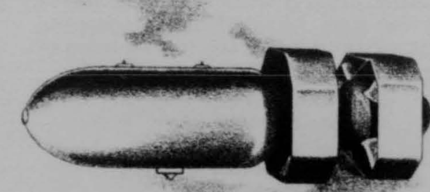
The control surfaces are actuated by radio signals transmitted by the bombardier of the launching airplane. The bombardier tracks the bomb by means of a television set in the nose of the bomb which enables him to view the area toward which the bomb is heading. The GB-8 was used to some extent against targets in Europe but the results were not sufficiently satisfactory. The bomb is too dependent upon good visibility for control; its low speed, (250 miles per hour), makes it vulnerable to antiaircraft fire, and the fact that it is carried externally slows down the launching aircraft.

Weary Willie

Weary Willies are old heavy bombers stripped down and loaded with TNT. During World War II, they were taken off by human pilots who bailed out after a mother aircraft had taken control. The Weary Willie was then flown to and crashed on the target by remote control from the mother plane. Because of intense antiaircraft fire, adverse weather, and equipment failures little success was attained. However, experimentation with remote control of aircraft is continuing.

Bat

Bat, a Navy guided missile, was an air launched, radar-homing glide bomb of 10 foot wing span and carrying a 1,000 lb. conventional bomb. Several of these missiles were used but little success was experienced.



VB-3 RAZON

Razon

Since the end of the war, the Air Force has been developing several missiles. One of these, **Razon**, is similar to Azon, the principal improvement being the added ability to control the bomb in range as well as azimuth. It is a highly accurate weapon and is believed to provide over twenty times the normal probability of hitting pin-point targets; it is thirty times as effective for maneuvering targets. Its main drawbacks are the necessity for visual control and the fact that it is possible to control only one bomb per radio channel.

Felix

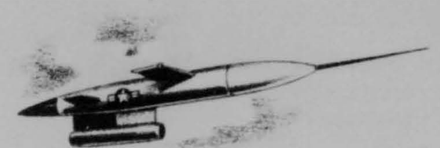
Felix is a standard 1,000 lb. bomb for attack against targets which give a differential heat radiation from the surrounding area.

VB-6
HEAT SEEKING
BOMB

Heat-homing guidance is obtained by a heat-seeker assembly in the nose which applies proper corrections in range and azimuth to a special tail assembly. The missile is accurate but limited to use in clear weather.

Navy Missiles

Brief comment should be made upon some of the Navy missiles under development. The following types are representative of the work now being done:



Two types of surface-to-surface missiles similar to the German V-1.

Two air-to-air missiles with liquid rocket propulsion.

Various glide bombs similar to the Bat, one of these having rocket propulsion to increase range.

A glider bomb towed to the launching point, with television intelligence and radio control.

A heat homing verticle bomb.

A glide torpedo.

Army Missiles

The Department of the Army has three projects now under way in the guided missile field. Two are concerned with the development of one or more types of short range, tactical, guided missiles, while the other is concerned with establishing a knowledge of supersonic flight, jet propulsion, and the makeup of the extreme upper atmosphere. It is in this latter project that the Army is firing the captured V-2s and the Army developed WAC series.

Figure 3-1 Surface to Air Guided Missiles

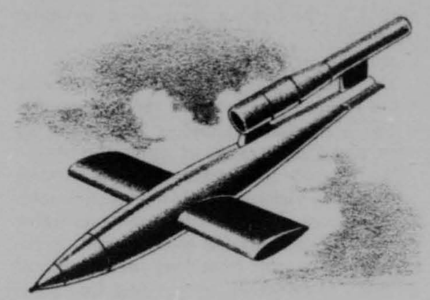
2. GERMAN GUIDED MISSILES

There is no doubt that the Germans were far ahead of the field in the development of guided missiles. They built a few air-to-air and air-to-surface missiles but their main and most successful effort was with surface-to-surface missiles, the best known being the V-1 and V-2.

V-1

The V-1 was a pilotless aircraft propelled by a pulse jet engine. It was about 25 feet

long, had a wing span of 17 feet, and weighed 5,000 lbs. Launched either from an airplane or the ground, it had a range of about 150 miles, a speed of about 400 miles per hour, and normally operated at or below 3,000 feet. The V-1 was not controlled from an external source, having an internal gyro for stabilization and a compass for direction.



About 8,000 V-1s were launched against London of which 2,300 actually hit the target. Although the V-1 was unsuccessful in the desired accuracy and was very vulnerable to countermeasures, nevertheless, it was an extremely effective weapon when consideration is given to the amount of damage it did to property as well as to civilian morale.

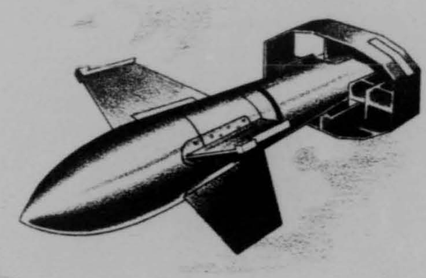
V-2

The V-2 was one of a series of ten rockets which had been under development by the Germans since 1929. It was a supersonic, cigar-shaped rocket, about 46 feet long and 6 feet in diameter. It reached a velocity of about 3500 miles per hour, had a range of about 200 miles, and a maximum altitude of 50 miles. The total weight of the rocket was about 14 tons. The missile was launched vertically and combined the action of a controlled missile with that of a free objectile, using all of its nine tons of fuel in the first sixty seconds of flight. In four seconds it reached an altitude of 2,000 feet when a time switch actuated a pitch control system which tilted the rocket to an angle of 47 degrees with the horizon. It then continued in straight flight along this path until it had reached the precomputed velocity required for it to hit the target. At this point the fuel was cut off and it became a free and uncontrolled body in space. When the rocket returned to the denser atmosphere it was slowed down to about 2,500 miles per hour by air friction.

About 2,000 V-2's were fired at London, of which 1050 hit the target area. The accuracy of the rocket has been estimated at about 1 per cent of its range, i.e., at 200 miles range it would strike within two miles of its target. This limitation, however, was probably not nearly as important as the large amount of effort required to deliver one ton of explosive. However, when one considers that the V-2 was one of a progressive series of rockets with the ultimate design, the A-10, planed for launching against New York in 1946, its potentialities are certainly worth consideration, especially since there is evidence that the Germans intended to use an atomic warhead in the A-10.

Fritz-X

The Fritz-X was a 3,000 lb. armor-piercing, air-launched, high-angle, guided bomb. Designed for either wire or radio control, it was used in the Mediterranean where it sank the Italian battleship "Roma."



HS-293

The HS-293 was an air-launched, rocket-assisted, radio-controlled, glide bomb. It attained a speed of 375 miles per hour and had a range of 5½ miles. Some success was experienced with the bomb against shipping in the Mediterranean.

In addition to the missiles mentioned above, there were three weapons which were developed by the Germans but not put into operational use before the end of the war:

Schmetterling

The Schmetterling was a rocket-propelled, radio-controlled missile designed to be launched from the ground against our bomber formations.

Wasserfall

The Wasserfall was a surface-to-air missile, somewhat similar to the V-2 although smaller, with four control wings. It was guided to the bomber formations by radar tracking.

Enzian

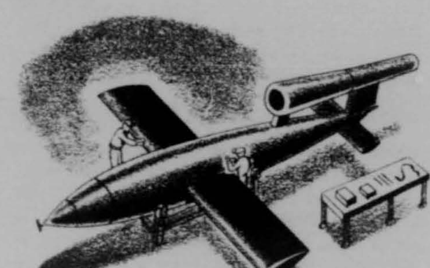
The Enzian was a surface-to-air missile, liquid-rocket propelled, and radio-controlled. It has a maximum speed of 600 miles per hour, and a slant range of about 15 miles.

Many people have referred to the German scientists as visionaries. However, they actually produced significant developments which placed German missiles years ahead of the rest of the world. That they were forward thinking is evidenced by the fact that some of them were actually planning such things as satellite rockets and space observation platforms.

SECTION III - MISSILE GUIDANCE

1. GENERAL

One of the most important problems connected with the development of guided missiles is that of guidance. Of course, the ultimate objective in guidance is to devise a system which automatically will control the path of a missile so that it will have a high probability of scoring lethal damage on a target in all combat situations. In general, guidance and control furnish the directive brain and nervous system for control of the missile under all conditions of flight. The technical problems in guidance and control of a missile are substantial; essentially the same performance is required of the missile as is now obtained from a fully-manned B-29, namely, reaching out long distances, locating a target, and then destroying it. However, one must add to this problem the perfection of a system able to handle both stationary and moving targets; a system that can handle more than one missile at a time, with freedom from enemy jamming, and above all, a system having accuracy at the distant



JB-2

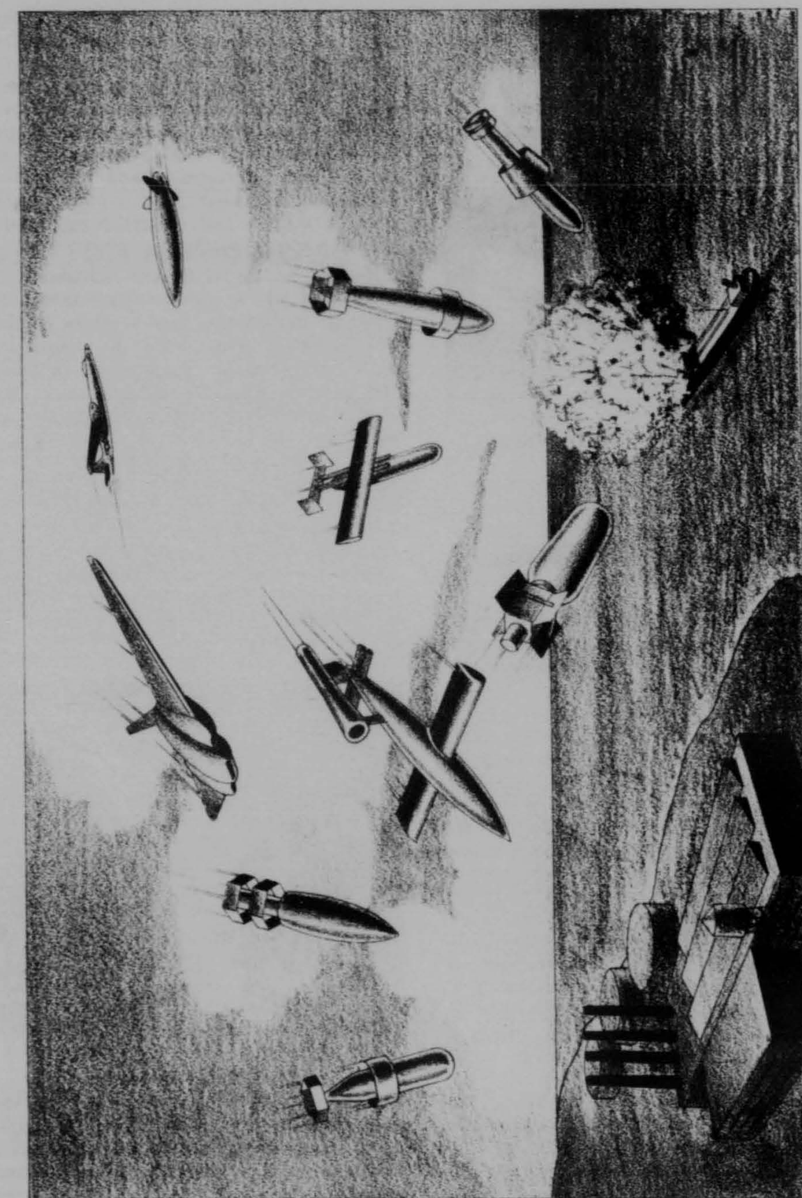


Figure 3-2 Guided Missiles Chart

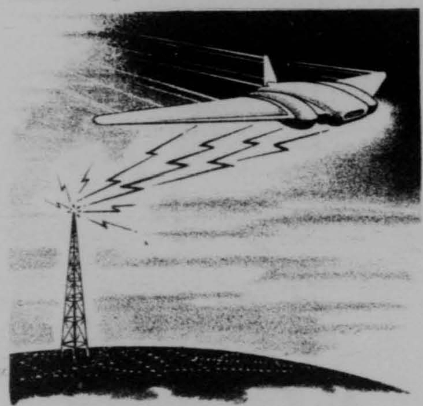
THIS PAGE IS DECLASSIFIED IAW EO 13526

point of impact equivalent to that of artillery fire.

There are a great variety of possible guidance systems. The basic ones are: Preset Guidance; Course Seeker Guidance; Command Guidance; Homing or Target Seeker Guidance.



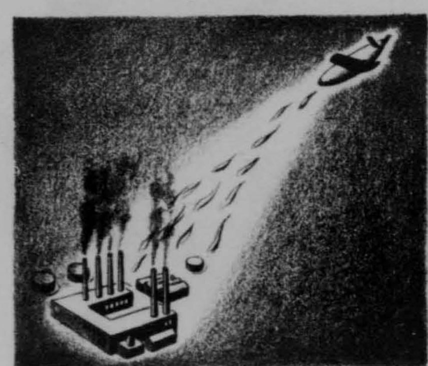
Preset Guidance is that in which the missile may follow a course which is completely determined before the missile leaves the ground.

Preset control has certain advantages in that it is self-contained and self-directed. The control system is free from countermeasures and interference and the missile can be flown along paths and at altitudes for which the fuel requirements are low. Nevertheless, the system has its shortcomings. Its accuracy decreases with the increase in range, there is a low probability of hits with a single missile except in area targets, and it is not effective against moving targets.

Course Seeker Guidance makes use of radio aids to navigation, and triangulation, to determine the constant exact position of the missile; the missile is directed along a radio beam. This latter method is called beam rider. In this system, the accuracy decreases with range, but the ability to handle a large volume of traffic is a definite advantage.

Command Guidance is a system in which equipment is provided for determining the present position of both the target and the missile. Then signals are transmitted to the missile to guide it along the desired course to the target. Command Guidance is the most flexible of all guiding systems since it provides directive control of the missile along the desired course. Its disadvantages are its susceptibility to jamming and its limited traffic-handling capacity since each missile must be tracked and controlled separately from the control station.

Homing or Target Seeker Guidance. All methods of missile guidance have the characteristic of becoming less accurate as the missile moves away from the source of control information. The ultimate in guidance accuracy would be realized if the source of such control information were located at the target itself. A homing system is one which makes use of some feature of the target to cause the missile to be directed toward that target. Radar, radio transmission, and infrared have been proposed for use in homing guidance. (The Germans were developing a sonic means at the end of the war.) Three types of target seeking devices are built in to the missile to increase the accuracy in the last stages of flight.



The automatic Radar Seeker is merely an extension of the fire control radar with the controls extended to the missile controls. Because good radar definition is required, a radar seeker is satisfactory for isolated targets such as ships and aircraft, but it is not

much use against normal ground targets.

Light and heat seekers are dependent upon the light or heat differential between the target and the surrounding area. These are best for targets of opportunity. A type of seeker in this same category is a **radiation seeker** which is sensitive to radioactive targets such as atomic piles and atomic bomb plants.

Radio seekers would home on enemy radio stations or small beacons planted by friendly agents.

SECTION IV - ORGANIZATION

1. GENERAL

Evidence of the great importance attached to the guided missile program by our national planners may be found in the study of the organization set up to control the development of the program.

The coordinating agency on the top level is the National Research and Development Board. Perhaps the most interesting result of this coordination is the policy concerning operational responsibilities: which particular service will operate the various types of missiles. The Army and Air Force agreement of 15 September 1947 provided, in general, that: tactical surface-to-surface missiles which have a direct effect upon the current Army tactical operations are assigned to the Army; surface-to-surface missiles which do not directly affect current battlefield operations, but which are suitable for strategic bombardment, are assigned to the Air Force; surface-to-air security missiles (battlefield defense missiles) will be assigned to the Army, while those employed in area air defense will be assigned to the Air Force. The Air Force will also operate air-to-air and air-to-surface guided missiles.

A second organizational unit is the Air Coordinating Committee of which a subcommittee concerns itself with guided missiles. This organization considers all air matters pertaining jointly to the Air Force, Navy, Army, National Advisory Committee for Aeronautics, etc.

Staff Organization. Within the staff structure of the Headquarters, United States Air Force, are two offices primarily dealing with the guided missiles program. Under the Deputy Chief of Staff, Operations, there is a Guided Missiles Group charged primarily with requirements, organization, training, and operations. Under the Director of Research and Development, Deputy Chief of Staff, Material, there is a Guided Missiles Branch charged primarily with formulating a guided missiles research and development program.

Command Organization. Within the command structure of the USAF, the Air Materiel Command is the agency responsible for the execution of research and development. Holloman Air Force Base, adjacent to the Ordnance White Sands Proving Ground, is the main AMC testing facility for guided missiles, while the 1st Experimental Guided Missiles Group, a flying unit, is concerned with the service tests and determination of tactics and techniques for guided missile use.

SECTION V - SUMMARY

GENERAL

This chapter on guided missiles can best be summarized by a brief resume of Air Force requirements for guided missiles. Since requirements precede developments, such a resume will also afford a glimpse as to the future course of missile development.

Included in all of the military characteristics lists are performance requirements listed in the order of operational priority.

THIS PAGE IS DECLASSIFIED IAW EO 13526

Of high priority on all lists are accuracy and speed. We must have accuracy or guided missiles will never be used operationally because of their inherent high cost in money, material, and manpower. Speed is very important because it is in speed that guided missiles will find the invulnerability which is so promising.

In the air-to-air category, the operational requirements for adequate defense of bombardment aircraft and for increase in firepower for fighter aircraft have indicated a high place on the list for air-to-air missiles. Against air targets, accuracy and warhead requirements are interdependent. In general, it is felt that one out of two missiles must be placed close to the target and the warhead must make a positive kill when so positioned.

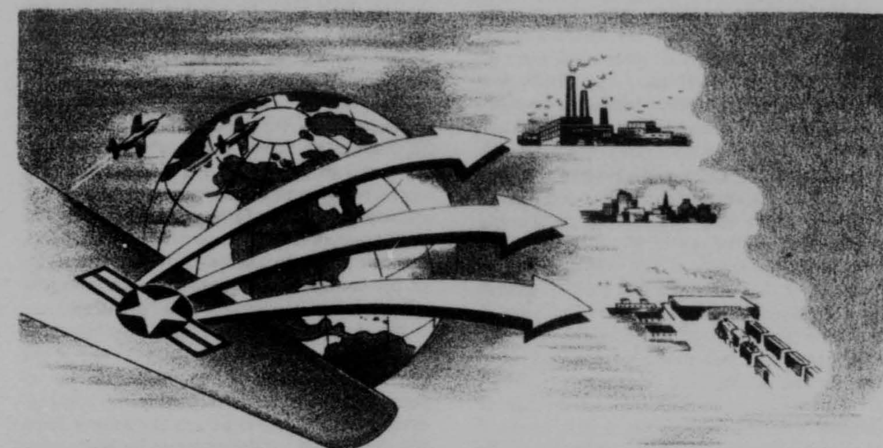
The demand for improved accuracy and effect in air-to-surface bombing, plus the desire to keep the bombers outside the range of ground defenses, has led to the establishment of requirements for air-to-surface guided missiles to supplement, and possibly replace, conventional bombs.

The requirement for the defense of both military and industrial installations against guided missiles and bombardment aircraft has resulted in the formulation of military characteristics for surface-to-air guided missiles.

The desirability of increasing the offensive bombardment power of the Air Force has made full investigation of surface-to-surface missiles advisable. The ability of the surface-to-surface missile to operate equally as well under all conditions of weather, defense, and range makes it the "ideal weapon," the weapon which military leaders have desired since the days of the sling and the bow. It ultimately represents all that could be required in range and destruction.

When these requirements are studied in relation to accomplishments, one finds that the art of the design and operation of guided missiles is still in its early stages. It may be stated with confidence that a war fought primarily with guided missiles is not a technical possibility within the next few years whether it be carried on by the United States or by any other great power. American technicians feel that America is as far advanced, if not further, than any other nation. But, in spite of this, pushbutton warfare is not just around the corner as many people seem to believe.

CHAPTER 4 - AIR DOCTRINE



SECTION I - DEVELOPMENT OF AIR DOCTRINE

1. HISTORY

P-1-7

The military doctrine of the use of the airplane as a weapon has been undergoing a gradual evolution since the days of the first heavier-than-air craft. It has been an uphill fight all the way, characterized by publicity, bitterness, and recrimination. The great debate over air power has revolved around the acceptance of a fundamental doctrine that the airplane possesses such flexibility and such advantages of speed and altitude as to enable it to destroy all surface installations.

If the accuracy of that doctrine is conceded, the predominance of the role of the Air Force in the national military establishment and the necessity of planning all campaigns to insure the most advantageous conditions for our air power seems logical. The protracted controversies over the relationship of the air force to surface forces in a military organization has been reflected in the struggle of the advocates of air power to free it from the organizational and operational confines of surface command. The difference of opinion between the most zealous adherents of air power and the most stubborn and dogmatic of the skeptics has not been over theories of strategic or tactical employment of the available weapons; it has revolved about the fundamental power of a particular weapon.

The advocacy of air power as the predominant instrument of war gained in force when it came from men who had been subjected to the tests of actual warfare. World War I brought to the fore two men who remained the leading protagonists of the doctrine of the supremacy of aircraft. For a dozen years thereafter their writings played a large part in the evolution from a simple faith in that doctrine to its use as the basis for theories of employment of forces and selection of objectives.

These two men, Guilio Douhet and William Mitchell, led lives that were strikingly parallel. Both entered the army in youth. Both possessed an imagination which led them to seek employment in connection with the promotion of other mechanical novelties in the military service before they were attracted to aviation. Both became severely critical of the military leadership of their time and suffered punishment in military courts for their criticism and the manner of its expression. Both were fluent and appealing writers; Mitchell addressed himself, in his published writings, primarily to persuading the public, while Douhet wrote more specifically for a professional, military audience.

Douhet. Guilio Douhet was born in 1869 and died in 1930. He entered the Italian Army as an artillery officer and first wrote of the importance of air power in 1909. By 1915, he had already conceived the image of total war and of that shattering of civilian morale by air attack which played a large part in the later evolution of his thought. He also advocated the "destruction of nations" from the air as a military measure. In 1916, after he had sent to a member of the Italian cabinet certain memoranda highly critical of the existing policy of the Italian staff, he was court-martialed and sentenced to a year of imprisonment. The decision of the court was formally repudiated in 1920. In the meantime, he had been recalled to service and placed at the head of the Central Aeronautical Bureau. Douhet attained the rank of General in 1921, the year from which his first serious writings on air power date. He was designated commissioner of aviation immediately after the Fascist march on Rome, but he withdrew from the government to concentrate on the literary advocacy of his views.

There are two major assumptions underlying Douhet's theories of air power. One assumes that aircraft are instruments of offense with incomparable potentialities against which no effective defense can be foreseen. The other assumes that civilian morale will be shattered by bombardment of centers of population. It was on this foundation that he proposed his doctrine, the essential elements of which may be paraphrased as follows:

To assure an adequate national defense, it is necessary and sufficient to be in a position to gain command of the air.

The primary objectives of aerial attack should not be the military installations alone, but industries and centers of population remote from the contact of surface armies.

An enemy air force, in particular, should not be dealt with by combat in the air, but primarily by destruction of the ground installations and of the factories from which its supplies come.

The role of surface forces should be a defensive one, designed to hold a front and to prevent an enemy advance along the surface, and in particular, an enemy seizure by surface action of one's own communications, industries, and air force establishments. The development of one's own aerial offensive, meanwhile, is proceeding with its paralysis of the enemy's capacity to maintain an army and the enemy people's will to endure.

Of the correctness of the first of these conclusions there can be little doubt, if the phrase "command of the air" is to be interpreted in a very strict sense. If a belligerent state is able to attack the enemy from the air at will, all defense having been liquidated, the victory of the nation having the free use of air power is inevitable. The conclusion is sound, but the primary difficulty arises in obtaining the necessary command of the air.

It was in his insistence upon the second of his basic conclusions, the preference of the industrial over the military objective, that Douhet most closely anticipated future strategy. The importance of the industrial objective has grown with the passage of time.

Perhaps one of Douhet's more faulty reasonings was his belief in the effect aerial bombardment would have upon civilian morale. The events of the past war have not borne out his contention that the people would break under such an attack. However, it should be remembered that he was thinking in terms of a saturation attack made after all opposition had been reduced. Perhaps, with the atomic bomb, his ideas along this line eventually may be proved to be correct.

Although Douhet's writings give surface forces an explicit function in defensively holding a surface line, (a corresponding role was contemplated for naval forces), the implication is strong that, with proper development in the use of air power, the progress

of events would be so swift that only a comparatively short delaying action would be needed before the issue had been otherwise decided.

In addition to his specific conclusions as to how a campaign should be conducted so as to make use of the overwhelming power of an air force, Douhet had ideas on military organization and general policy. He was an unrelenting advocate of the unification of the military, naval, and air organizations. He stated that there were theories of land war, naval war, and air war; that these theories exist, evolve, and develop, but that a theory of war—total war—was almost unknown. Therefore, he advocated the organization of national defense through a central ministry, and in 1927, such an organization was created in Rome.

The influence of Douhet's writings has been far-reaching. Much of what he said has been supported by experience. Much, on the other hand, has proven either over-optimistic or specifically erroneous. Some of his beliefs were proved unsound during the past war; yet the trend in development has, in most respects, been in the direction that Douhet foresaw. He went far astray in his specifications as to the characteristics of the aircraft that would be used in future wars. However, his judgment of the ways in which they should be used is more nearly valid now than it could have been under conditions existing during his lifetime. Further development is likely to bring the strategy and tactics of air power still closer to the practices advocated by Douhet.

Michell. General William Mitchell's activities were contemporaneous with Douhet's. The conventional assignment of Douhet's name rather than Mitchell's to much of their common belief is due in part to chance, in part to Douhet's clearer and more systematic literary development of his conclusions, and partly to the livelier interest in military studies in Europe as compared with that in the United States.

Mitchell shared in some degree, although without Douhet's complete confidence, the conviction of the prime efficiency of attack upon the enemy's economic and industrial structure. He shared the belief in the comparative fragility of civilian morale. Like Douhet, he believed in the possibility of paralyzing civilian and industrial activities through a relatively modest volume of bombardment. He stated that the advent of air power, which can go straight to the vital centers and either neutralize or destroy them, had put a completely new complexion on the old system of making war. It was now realized that the hostile main army in the field is a false objective and that the real objective is the vital centers. The result of warfare in the air would be to bring about quick decisions. Superior air power would cause such havoc, or the threat of such havoc, that a long drawn out campaign would be impossible.

In Mitchell's first writings after 1918, he gave much attention to the collaboration of air with surface forces. But, as time passed, surface forces receded more and more into a secondary position in his estimation and his confidence in the technical capacities of the airplane grew. He continued, however, to attach a great importance to the use of air power for the destruction of enemy surface forces. In this respect, he differed from Douhet who virtually was willing to ignore the surface forces while destroying the nation and the resources behind them. The difference was partly a reflection of the difference in nationality and in the geographical outlook of the two men.

Many American advocates of air power as the primary element in our military organization have written of the defense of the continental United States as our primary military concern. Mitchell never accepted any such limitations. He was the first to discuss the application of air power—with a minimum of support by surface forces—in global terms. He was a tireless advocate of the Arctic air routes between the continents. He dwelt endlessly upon the value of a trans-Atlantic route by way of Greenland and Iceland and its feasibility for military use; he pointed to the corresponding value and feasibility of aircraft movement between the United States and Asia by way of Alaska and Siberia, or by the Aleutian and Kurile Island chain. Very early in his military career he marked Alaska as the key to military supremacy of the

THIS PAGE IS DECLASSIFIED IAW EO 13526

Pacific.

As a military pilot personally experienced in the actual command of air forces in battle, General Mitchell was much more intimately acquainted than Douhet with tactical problems. He employed his talent to the full in the improvement of existing tactical methods. One of his most strikingly farsighted proposals was a plan for using parachute troops behind the enemy lines in 1918.

In matters relating to the technical characteristics of aircraft and to the details of their operation, Mitchell was incomparably more expert than Douhet. The intensity of his enthusiasm, however, led him on occasion to overestimate greatly the rate at which technical progress would be made in the near future.

Mitchell, as Douhet, favored the emancipation of the air force from the ground armies. He felt that only through an independent air force, controlled and operated by airmen, could the United States realize the full potential of air power. In the conflict which characterized the long struggle of the air force to achieve independent status, Mitchell wrote and spoke as an intense partisan, becoming more and more impatient with opposition and increasingly disposed to denounce it as stupidly reactionary, blinded by self interest, and dishonesty.

As a result of the manner in which he presented his views, he was, as was Douhet, court-martialed and sentenced to reduction in rank for five years. Shortly, thereafter, he resigned from the Army.

Mitchell's doctrine of air power can be summed up by a statement he wrote in 1930: "War is the attempt of one nation to impress its will upon another nation by force after all other means have failed. The attempt of one combatant, therefore, is to so control the vital centers of the other that it will be powerless to defend itself. The advent of air power which can go to the vital centers and entirely neutralize or destroy them has put a completely new complexion on the old system of war. It is now realized that the hostile main army in the field is a false objective and the real objectives are the vital centers. The old theory that victory meant the destruction of the hostile main army is untenable. Armies themselves can be disregarded by air power if a rapid strike is made against the opposing centers."

Many of his predictions have come true. Others will be realized in years to come. However, many of the technical developments which seemed to him to be on the horizon are still far from being in practical use. General Mitchell was immensely imaginative, both in technical matters and in tactical ones. It was even more true of him than of Douhet that he characteristically foresaw the direction in which progress would be made, but was often oversanguine about its rapidity.

Seversky. Alexander de Seversky was a Russian military pilot during the first World War and, subsequently, an inventor, airplane designer, and author. He has consolidated his views on air power, its potentialities, and the defects in its present use in his book, "Victory Through Air Power."

Although his views, in large part, follow those of Mitchell, the outstanding feature, which characterizes him above all the other students of the subject, is the insistence upon the vital importance of a large radius of action. He emancipates the air force of the future from concern with extensive ground supporting organizations and from dependence upon the air bases of the Arctic routes in the Atlantic and Pacific to which Mitchell attached such great importance. He maintained in his book that: "It is sheer waste to maintain advanced bases instead of hurling the full aerial potential directly against the adversary. The entire logic of aerial warfare makes it certain that ultimately war in the skies will be conducted from the home grounds, with everything in between turned into a no-man's land."

The advocates of air power have been the object of constant attack by conservative critics on the grounds that they propose to win wars with imaginary instruments and that they reach their conclusions by endowing aircraft with potentialities far exceeding those actually available. Against Douhet the charge has only a very limited pertinence; against Mitchell much more validity; and against Seversky even greater validity.

Since World War II, Douhet has been in

the background probably because some of the points of his theory have not been borne out. However, in the light of the present day potential the modern air weapon comes closer to fulfilling Douhet's expectations than did the aircraft of World War I. Furthermore, Douhet, were he writing today, would have seized upon the atomic bomb as the ideal instrument of air power.

Looking at the writings of Douhet from a broader viewpoint, we see that his theory not only embraces the entire subject of aerial warfare but also encroaches on that of war in general. It predicts that air action will have a decisive effect on the outcome of future wars; it also recommends that the three branches of the armed forces of a nation be co-equal under a single directive head and proposes that in allotment of funds the air arm receive the preponderance.

Military analysts have pointed out many things we have learned about air power in World War II. The overwhelming majority realized that air power had been too long bound to the army and that it should be established as co-equal to the ground and sea forces. This was accomplished by the National Security Act of 1947. It is interesting to note that, in spite of the belief that this was a new and a bold move, an almost identical act had been presented to Congress in 1923 and, furthermore, this act followed almost to a letter the original pronouncement made by Douhet.

Today the three long sought after goals of American air power have come into being. There exists an independent air force; there is in existence a tried and sound doctrine for the global use of strategic air power; and the long range air weapon to accomplish this mission is in sight.

SECTION II - STRATEGIC AIR POWER

1. GENERAL

Air power has been defined by the Air University as the **"total aviation capacity of a nation-civilian and military, commercial and**

THIS PAGE IS DECLASSIFIED IAW EO 13526

private, potential as well as existing." An air force, then, may be considered as the military component of air power. This section deals with the application and employment of an air force in a strategic role.

Prior to World War II, there were two types of decisive military action. First, a ground army could defeat a hostile ground army and, subsequently, defeat the enemy nation. Second, a navy could strangle an enemy nation by controlling the sea lanes of communication and, thereby, cause capitulation of the enemy. During World War II, a third category of decisive military action was developed. That category is air action. It was shown during the war that air power applied directly against the vital points of the enemy's national structure can cause the defeat of that nation.

During the period 1939-1942 the Germans were overrunning Europe; their successes were dazzling and ominous. The question in everyone's mind was, "How can we stop the German blitzkrieg?" The answer was not readily apparent. It was arrived at through the perseverance and foresight of the Allied air leaders. They saw the strategic possibilities of air warfare. It was not easy for our air leaders to support a strategic concept on the use of air power when the Germans were achieving outstanding success with their air arm tied to surface action.

It was not until 1943, at the Casablanca Conference, that the strategic concept of the use of air power was given an official blessing. This conference resulted in the definition of strategic air operations as we think of it today. **Strategic air operations are air operations aimed at the destruction and dislocation of the enemy's military, industrial, economic and political system and the undermining of the morale of the enemy's people to the point where his capacity for armed resistance is fatally weakened.** This definition is the very core of the present day doctrine of strategic air power.

2. MISSIONS OF A STRATEGIC AIR FORCE

The primary mission of a strategic air force is the implementation of the concept that air power effectively employed against the vital points of an enemy's national structure can be decisive in a war. More specifically, the primary mission of a strategic air force is the destruction and/or neutralization of assigned objectives within an enemy controlled area. This means that the strategic air force will train and prepare to destroy or neutralize industrial targets, transportation targets, armament targets, or any system of specific targets which permit an enemy to conduct war.

It should be realized that in the future it may be highly desirable to deny certain areas to the enemy without destroying those areas, in order that existing installations may be used again. Under such circumstances the mission becomes neutralization rather than destruction, e.g., aerial mining of a harbor rather than the destruction of port facilities.

In World War II, the accomplishment of this primary mission was not possible until the attacking strategic air forces had gained air superiority in their areas of operations to such a degree that penetration to strategic targets could be made within the limits of acceptable losses. Thus, the gaining of air superiority was a prerequisite mission which was actually a part of the primary mission. It should be emphasized that this prerequisite mission was the means to an end. The end was the capability of penetration. In future wars we may achieve penetration by surprise, speed, the cover of darkness, or bad weather, or by special technological advances. Thus, in a future war, we may be satisfied to attain momentary air superiority by these means rather than fighting for the control of the sky as we did in World War II.

The strategic air force may, of course, be assigned other missions than the primary one, if and when the situation warrants it. One mission in this category is direct cooperation with the surface forces. In this case, the strategic air force reverts to the role of a tactical air force. Two outstanding examples of this type of mission were the utilization of the Eighth Air Force in direct support of the Normandy invasion and the diversion of the Twentieth Air Force to bomb airfields in Kyushu in support of the Okinawa invasion. The strategic air force might also

be given such missions as air supply, search and rescue, or simply training for a future mission. All these missions, however, are subsidiary to the primary mission of a strategic air force.

There should be little doubt as to the normal priority of the missions assigned to a strategic air force. If we truly advocate the concept that air power properly employed against the vital points of an enemy's national structure can be decisive, then relentless prosecution of the primary mission should be the objective of the strategic air force. It is designed as a tool to be used to destroy or neutralize an enemy's means and will to carry on a war. A strategic air force wins wars by progressive destruction or neutralization of an enemy's vital targets, thereby, denying to an enemy the ability to maintain an armed force. It is, therefore, the objective of a strategic air force to win wars, not battles. Such a concept calls for extreme caution before any attempt is made to divert a strategic air force from its primary missions to secondary ones.

3. TYPES OF STRATEGIC AIR OPERATIONS

The accomplishment of the primary and subsidiary missions of a strategic air force requires the employment of many different types of strategic air operations. The choice of the types to be employed in any given place at any given time will, of course, depend upon the nature of the situation and the current objectives.

Bombardment. The main type of air operation performed by a strategic air force is bombardment. Bombardment includes bomber and fighter operations, the purpose of which is to destroy or neutralize. The bomber aircraft is today the main carrier of destructive force employed by the strategic air force and will probably continue to be so until better agents are developed. This is true despite the disadvantage of bomber aircraft. These include its vulnerability to antiaircraft fire, its need for fighter escort for deep daylight penetrations, and the fact that it is still somewhat subservient to weather. The escort fighter is a major problem at present because of its range. Certainly, the escort fighter is mandatory at present if bomber operations are to be conducted in daylight. Bombardment operations, employing both bomber and fighter aircraft, are consequently the most important type of strategic air operations.

Aerial Mine Laying. A second type of strategic air operation is aerial mine laying. This type of operation proved very effective against Britain, Japan, and to a lesser degree against Germany in World War II. It is a highly effective and amazingly efficient means of throttling waterborne commerce. It should be considered as a weapon in any air attack against a nation which relies upon water transportation to support an important part of its economy.

Strategic Reconnaissance. A very important air operation which is performed by a strategic air force and which augments and supports the main strategic bombing and mining campaign is strategic reconnaissance. Reconnaissance is the life blood of the strategic air operations, and can be subdivided into photo, weather, radar, and radar counter-measure phases.

Propaganda. The strategic air forces, because of its tremendous destructive potential, may be employed to great advantage as an agent of psychological warfare. This can be done by two kinds of propaganda operations: 1) mass demonstration flights designed to impress the opposition, and 2) leaflet drops and similar operations, the purpose of which is to put propaganda material into the hands—and ultimately into the minds—of the enemy people in order to weaken their will to resist. The strategic air force probably would be directed to fly propaganda missions when it can be expected to be more effective than the actual application of force.

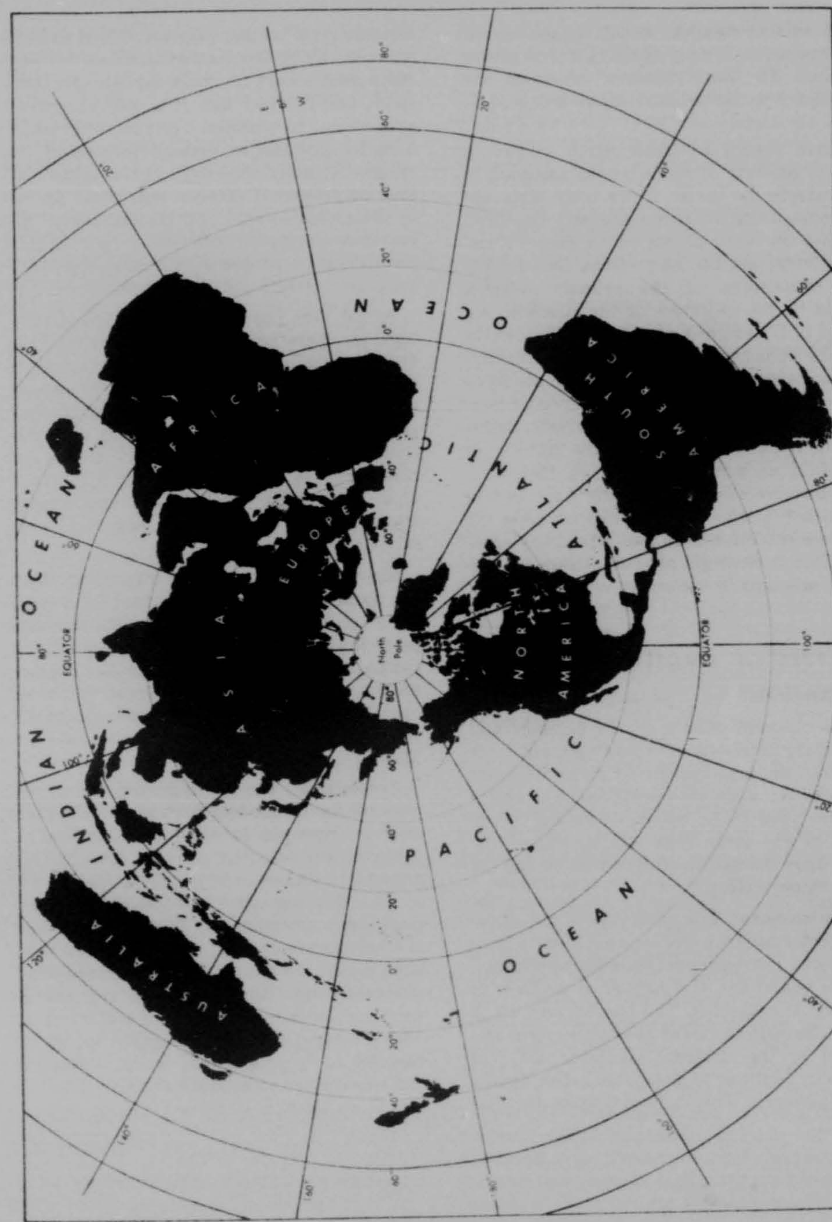

Figure 4-1 The World Showing Radius of Action of B-36 (5000 Miles) (Scale 0 —— 5000 miles)

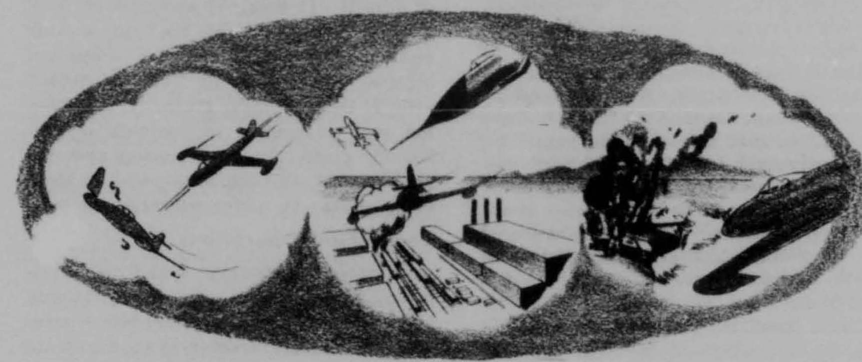
SECTION III - TACTICAL AIR POWER



1. GENERAL

Until World War II, military aviation had been used almost entirely for tactical operations. As lighter-than-air balloons were developed and, much later, airplanes, professional fighting men considered their use in the light of how they might benefit the army or navy. Although air operations brought some innovations in details of warfare, neither the generals nor the admirals altered their opinions of how to conduct a campaign until almost 150 years had elapsed after the first balloons were used by a military force.

Observation, the first function of military airmen, remained the principal activity for many years. In the middle of the nineteenth century an attempt was made to bomb an enemy with explosives carried by a balloon, and during the Civil War artillery spotting was done from balloons. The airplane entered the picture at the turn of the century and saw considerable service in World War I. The pattern of air operations changed but little, however, and observing the enemy remained aviation's major role. The attempt to prevent observation from airplanes introduced air combat. Aircraft weapons and antiaircraft weapons were soon developed and inevitably attacks were made upon ground personnel.

In recent wars, the theory of tactical operations has progressed somewhat. The Russians, Germans, and Italians who participated in the Spanish Civil War made some small gains, but the primary purpose of air operations was still to pave the way for the infantry and to interfere with supply and reinforcement. In World War II Germany misapplied her air power in a way that has become almost a classic example. Already possessing the world's greatest air force and a high degree of air superiority, Germany permitted its air units to remain tied to its ground armies. The necessity of maintaining air superiority was ignored. Although Germany opened World War II in a most logical manner by immediately destroying the Polish Air Force, the thinking of the German high command slipped back to the principle of subordinating air to ground forces.

Thus, for over a century the obviously apparent need for efficient tactical air operations had been misunderstood. Although air forces had, in the main, been used in a tactical role, the early phases of World War II showed no clear-cut concept of tactical air operations, nor were the air units organized, equipped, or trained for the specialized tactical tasks.

The current concept of tactical air power was evolved during the North African campaigns of 1940-1942. In June 1940, the RAF opposed a large, powerful, and modern Italian air force in Libya. Italian air units were dispersed among local army commanders and operated under the direct command of the Italian ground forces. The RAF, operating en masse as an independent air command, not only held its own but eventually destroyed the numerically superior Italian air force.

The German air force replaced the Italians and the fight for North Africa continued for two more years. Units of the USAAF joined the RAF in 1942 and the Allies gained air superiority and held it. The Allied Northwest African Tactical Air Force, formed from British and American units, was placed under one commander. The organization of this air force, which gained its victory in North Africa, became the prototype of a tactical air force organization.

The theories, for employing air forces in joint warfare, which evolved from the North African campaign became accepted principles. In North Africa was realized the cardinal fact of tactical air power; that the air forces available should be concentrated under one air commander who will work with the ground commander toward the same objectives. These theories were published in 1943 in FM 100-20 "Command and Employment of Air Power." This FM established three phases of tactical air operations as official doctrine. By the time World War II had ended, many modifications in techniques and organization had improved tactical air operations, but these general rules survived and are applicable today: a) a tactical air force should be organized specifically for tactical operations; b) associated air and ground commanders must almost literally live, eat, and work together; c) air superiority is a prerequisite before tactical air forces can operate with surface forces.

2. MISSION OF A TACTICAL AIR FORCE

It can be said that the wartime mission of tactical air power is to execute, either independently or jointly, sustained offensive and defensive operations aimed at the destruction or neutralization of a critical enemy military force together with its immediate reserves and supplies.

The operations of a tactical air force consist of three phases in the following order of priority: 1) Establish and maintain local air superiority. 2) Isolate the battle area by restricting movements of enemy troops and supplies into, within, or from the combat area. 3) Destroy enemy ground forces within the zone of contact in conjunction with friendly ground forces. Depending upon the local tactical situation, some or all of these missions may be performed concurrently.

Counter-air Operations

Counter-air operations need little justification, particularly to an airman. Attaining air superiority can secure the "three freedoms" of warfare: freedom of the air for air operations, freedom of movement for surface forces, and freedom of flow of supplies. When one side has all three freedoms and the enemy has none, the stage is set for victory.

Air superiority is that degree of capability of one air force over another which permits it to conduct operations at a given time and place, without prohibitive interference from the opposing air force.

Air supremacy is that degree of air superiority held when an air force can maintain almost continuous air superiority in all combat areas. Securing air supremacy is a gradual process. It cannot be obtained in a single engagement. But once obtained, the victor should employ his air force so that air supremacy is never relinquished.

The true goal of counter-air operations is air supremacy and not merely air superiority or air defense in local areas. Securing air supremacy is probably beyond the capability of the tactical air arm because it requires not only that the enemy air force be permanently paralyzed but also that the enemy's air power be reduced through attacks upon its supporting structure. Effort expended in attempting to annihilate an enemy air force may not be economical in terms of results obtained.

Counter-air operations may be divided into two phases; offensive and defensive. Offensive operations consist of attacks on air craft

Strategic knocks out the enemies potential for war
Tactical stays with the ground forces (ground)

on the ground or in the air, airdromes, supply dumps, and any facility which directly supports the air arm. Air defense is the effort designed to oppose an enemy air attack. In its role of air defense in support of either a strategic air force or a surface force, the first requirement of the tactical air force is to prevent, if possible, and in any case interfere with the accuracy of enemy air attacks against personnel and installations.

Isolation of the battlefield, also called interdiction, disrupts the enemy's lines of communication. Forces in an area are cut off by interdicting, or disrupting, their means of traffic with other forces. This implies that nothing can move into, out of, or within the isolated area. Although in actual practice isolation is rarely total, complete separation should be the goal. Action should be taken against all traffic significant to the enemy's military operations. Railroads, highways, waterways, and airways with their facilities and the transport moving on them are important targets. Their destruction will stop the replacement or withdrawal of troops and the movement of supplies.

Cooperation with the surface forces completes the part that the air force plays in winning a ground war. With air and logistical superiority our ground forces are ready to exploit the situation. It is during this phase that the fighter-bomber becomes the most potent and flexible weapon of the tactical air arm. Fighter-bombers can knock out strong points and tanks, bomb and strafe front line troops and supplies, silence guns, and furnish air cover for armored columns by providing observation and additional firepower when critically needed by the tank commander.

SECTION IV - SUMMARY

The basic doctrine of the use of air power is a doctrine of strategic bombardment. It states simply that air power, properly employed against the vital points of an enemy's national structure, can be decisive. This is accomplished by strategic bombardment, i.e., air operations aimed at the destruction and dislocation of the enemy's military, industrial, economic, and political systems, and the undermining of the morale of the enemy's people to the point where his capacity for armed resistance is fatally weakened. The ultimate goal of American air power is the ability to conduct strategic operations over any target in the Northern Hemisphere from bases in the United States. We are today within striking distance of that goal.

Tactical air operations will play a role in air power whenever there is surface action or the threat of it. General Kurt Von Runstedt, one of Germany's outstanding commanders, states that the greatest single factor in the defeat of Germany was the effectiveness with which the Allies used air power. He did not say defeat resulted from the Allies having more and better airplanes and pilots. He attributed it to the manner in which they used what they had. The Allies organized for the job and developed equipment and methods for a particular task. Furthermore, they evolved a concept of tactical air employment and stuck to it. That the concepts which helped win the last war will change is to be expected. It may even be that in a future war the main job of a tactical air force will be to prevent a hostile force from engaging our surface forces in battle while the strategic air force carries out its assignment.

Whether it be strategic or tactical, the importance of air power cannot and must not be under-estimated. The words of the United States Strategic Bombing Survey (European War) bear this out: "The German experience suggests that even a first class military power—rugged and resilient as Germany was—cannot live long under full-scale and free exploitation of air weapons over the heart of its territory. By the beginning of 1945, before invasion of the homeland itself, Germany was reaching a state of helplessness. Her armament production was falling irretrievably, orderliness in effort was disappearing, and total disruption and disintegration were well along. Her armies were still in the field. But with the impending collapse of the supporting economy, the indications are convincing that they would have had to cease fighting—any effective fighting—within a few months."

THIS MANUAL SUPERSEDES ConAC Manual 50-140-1, Vols. I, II, III.

Preface

THIS textbook has been prepared specifically for the college or university student who is participating in the Air Force ROTC program. It is one volume of a series designed to qualify him as an officer specialist in the United States Air Force.

The text is planned to indoctrinate the officer candidate in the fundamental principles of Air Force Armament, rather than to present a detailed treatise of the entire complex field.

In order to achieve maximum efficiency and effectiveness in the performance of his duties, the Air Force officer must be constantly aware of new developments in his specialty and its allied fields. A receptive mind, nurtured by supplementary research and reading, can be a vital force in the personal and professional development of the officer specialist throughout his career.

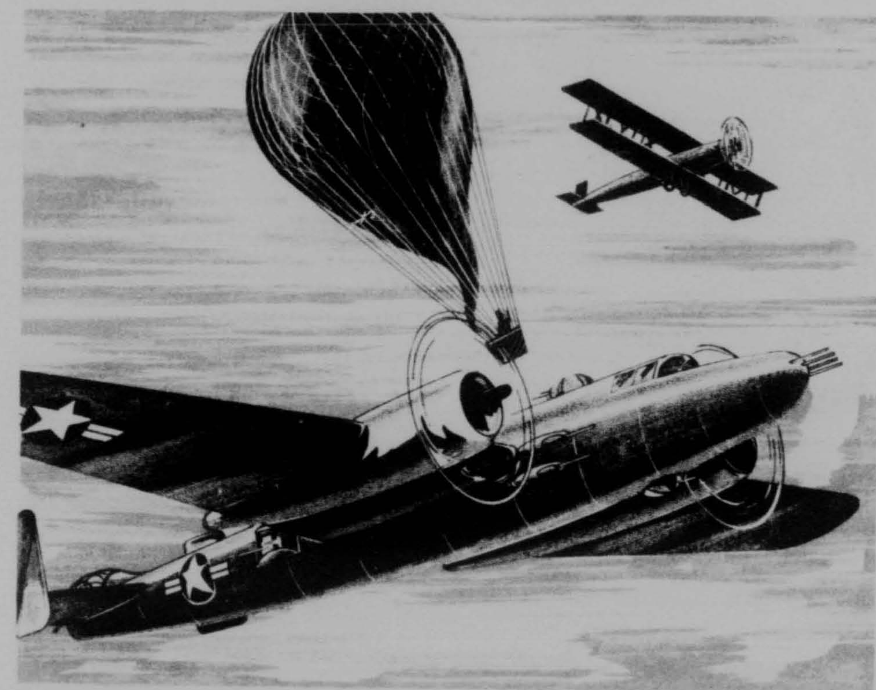
TABLE OF CONTENTS

CHAPTER 1—HISTORY AND DEVELOPMENT OF ARMAMENT



SECTION I—FROM BALLOONS TO CONVENTIONAL AIRCRAFT

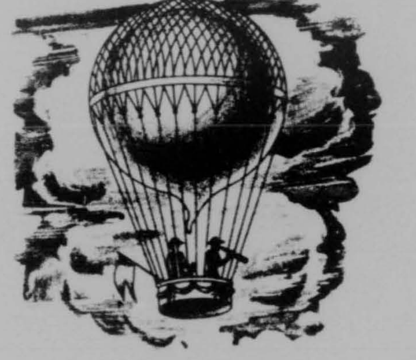
1. INTRODUCTION

The long span of centuries between mythical flight and recorded heavier-than-air flight was broken intermittently by the aeronauts (balloonists). First among these were the Montgofier brothers, who designed and built balloons capable of sustaining the weight of men in the air (1783).

The French were the first to employ balloons as an instrument of war. A large balloon, the "Entreprenant," was constructed and used successfully for observation purposes in the Franco-Austrian War. In 1794 it was used in the Battle of Fleurus.

The greatest disadvantage of the balloon as a means of military observation was that it could not be steered. Unless anchored, it drifted with the wind. Many attempts were made to provide devices to control the direction of flight, but to no avail. One of the most

THIS PAGE IS DECLASSIFIED IAW EO 13526



Entreprenant.

interesting ideas for making balloons steerable came from a staff officer of Napoleon's army during the Russian campaign (1814). This plan met with Napoleon's approval, and the first cigar-shaped gasbag made its appearance. The motive power consisted of several men who turned a large propeller by means of pedals. The speed attained, however, was a scant four miles an hour. Since that was insufficient to make headway against even a moderate wind, the man-powered dirigible was discarded.

In 1849 in a battle between the Austrians and Venetians, the Austrians found that the range of their batteries was too short to reach the city of Venice. When the wind was in the proper direction, blowing toward the city of Venice, the Austrians attached small bombs with time fuses to paper balloons. The balloons were capable of lifting the bombs to altitudes of thirty feet, and they drifted into the city. When well inside the city, the time fuses exploded the bombs. Although the material and physical damage which resulted was slight, the psychological effects were great.

In 1899, at the Hague Conference, an agreement was reached to prohibit the throwing of projectiles from balloons.

Nineteenth Century Progress

The nineteenth century was an age of rapid progress in engineering, yet it was frankly agnostic on the question of mechanical flight. This was the age in which the expression "might as well try to fly" had become a metaphor for the impossible. During this period there were men, daring and serious scientists, who refused to abandon the idea of flying. These men designed power-driven models and man-carrying gliders. In the closing period of the nineteenth century, three men were experimenting with power airplanes. These three men nearly succeeded.

Aviators

Orville and Wilbur Wright started their gliding experiments in 1900. Between 1900 and December 17, 1903, when power flight was achieved, the Wrights constructed the first wind tunnel; they made over one thousand glider flights and built an aircraft engine. The Wrights also devised two propellers which turned in opposite directions to eliminate torque.

It was not until Feb. 10, 1908 that the United States Government entered into a formal contract with the Wrights.

By 1910, military authorities of all the major powers had begun experimenting with airplanes. The airplane was regarded, however, as a more efficient means for gaining information in the field; its importance in dropping explosives in enemy territory was not yet considered seriously although in 1907, the restrictions of the Hague Conference were removed as far as bombing from the air was concerned.

The earliest recorded use of bombs dropped from airplanes was in 1912 by the Italians in Tripoli. These first bombs were converted from some other type of ammunition, probably artillery rounds.

First World War

The European, or First World War, started in 1914. Military aviation in Europe had developed much more rapidly than in the United States. At the start of this war, France and Germany each possessed about six hundred airplanes. They soon proved their worth in scouting and more and more reliance was placed on their work by the staffs of armies. Scouting soon changed to scouting and fighting. The opposing airmen began by firing at one another with sporting rifles and shotguns.

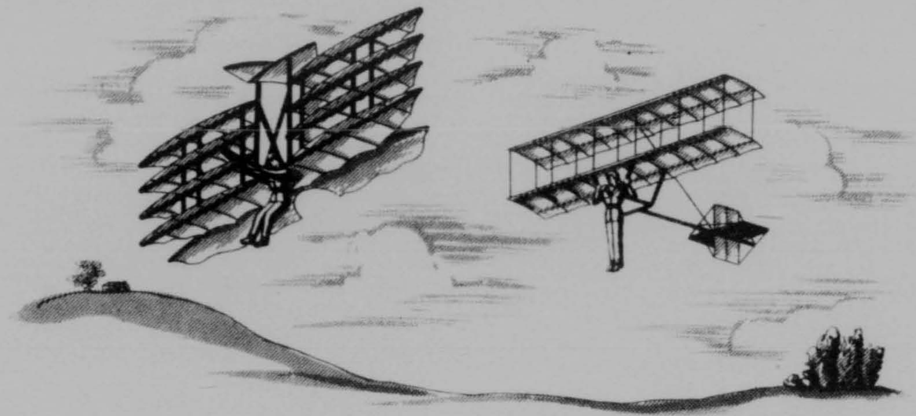


Figure 1–1. Chanute's Gliders.

Soon machine guns appeared, and then the Germans synchronized a machine gun firing between the blades of the rapidly-whirling propeller. By 1916, aerial fighting and bombing were being conducted on a grand scale. America's contribution was to ship overseas 740 airplanes, of which only 379 ever got to the front.

America's greatest aerial offensive did not get under way until the closing months of World War I. Under the American First Army, the greatest concentration of air power ever assembled during the war was massed for the September 1918 drive against St. Mihiel. A fleet of 1,481 planes, American, British, and French, under the command of Colonel "Billy" Mitchell, commenced a series of strategic attacks on German railway centers, communications, and troop concentrations.

On October 9, more than two hundred American bombers, accompanied by about one hundred pursuit craft and fifty-three 3-place planes, smashed a German counterattack by dropping twenty-two tons of bombs and knocking out a dozen enemy fighters. The bombs were released electrically from mounts underneath the fuselage. This was a decided improvement over the earlier bombing methods when bombardiers carried their bombs in a basket in the cockpit and tossed them overside by guesswork aiming.

Combat Statistics—World War I. Army air units, participating in 215 bombing raids, dropped over 255,000 pounds of explosives (on a single day in World War II the Air Force dropped approximately 10,000,000 pounds of bombs on Japanese installations alone); flew 35,000 hours over the lines; and took nearly 18,000 photographs of enemy positions. They regulated artillery fire, supported ground attacks, strafed and bombed enemy batteries, convoys, and troops.

Technical Developments

The United States did turn in a first-rate performance in the design and construction of the famous Liberty engine. The production rate was 150 a day. In addition to the Liberty engine, there were other outstanding technical developments during the World War I period. Some of these were: an oxygen mask equipped with telephone connections; wireless telephone with air-ground communications; electrically-heated clothing; automatic camera; helium gas; armored pilot seat; 8-machine gun ground strafing airplane, and great advances in aero-medical research.

SECTION II—AIRCRAFT ARMAMENT

1. GENERAL

Aircraft armament can be broken down into the following basic equipment:

Aircraft bombs and associated equipment
Aircraft machine guns
Aircraft cannons
Rockets
Cameras
Ammunition
Turrets
Gun sights

2. AIRCRAFT BOMBS

The prime requisite for military aircraft is to use their wide and highly-mobile striking power to drop bombs of various weights and for various purposes on enemy objectives. Bombs are manufactured in many different weight classifications because military conditions require attack on numerous objectives which require specific types of bombs.

Classification

Bombs may be roughly classified in the following groups:

Demolition bombs
Fragmentation bombs
Chemical bombs
Incendiary bombs
Practice bombs

The purpose of demolition bombs is clearly indicated by the name itself; they are designed to demolish and destroy enemy objectives by detonation of their high explosive content.

These bombs can be equipped with intricate mechanical devices which control detonation, thereby providing safety elements for the crew and the airplane and controlling the explosion of live bombs. Bombs can be made to explode instantaneously or delayed.

The atomic bomb is the latest developed bomb used for demolition purposes. Another bomb that is being developed is a 42,000-pound bomb.

Fragmentation Bombs

Unlike demolition bombs, which depend upon both the blast and the spread of bomb fragments for effect, fragmentation bombs require only that sufficient fragments are thrown outward at high velocities. These bombs are used mainly against personnel. Results are often dreadful, due to the proper combination of explosive content and metal parts of the bomb case.

The first fragmentation bombs were made from rejected 3-inch artillery shells, weighing seventeen pounds.

Many of the fragmentation bombs were dropped by parachute. This was done to protect the low flying aircraft from fragments of the exploding bomb.

Chemical Bombs

Chemical bombs have several purposes, some of which may be combined at times to obtain the desired effects.

Chemical bombs may be used for casualty effects, screening, and denying territory to the enemy.

Incendiary Bombs

The incendiary, next to the high explosive, is the most dangerous for destruction of property.

Magnesium and thermite are now the most common substances encountered in incendiary bombs. Petroleum and pitch were used to start fires at docks and water front areas. They were effective because petroleum's greatest incendiary effect is upward.

Practice Bombs

Bombs usually employed for practice purposes are obsolete types, or else special practice types manufactured in a much cheaper manner than is possible for standard service bombs. A specially manufactured type weighs one hundred pounds. This bomb has a five-pound black-powder, spotting charge, with the remainder of the bomb being filled with sand.

At the start of bombing, the bombardiers carried their bombs in a basket in the cockpit and tossed them overside by guesswork aiming. By the end of the first World War, simple bomb sights and automatic release systems were designed.

3. AIRCRAFT MACHINE GUNS

The cal. .50, Browning machine gun, M2, has very appropriately been referred to as the basic Air Force weapon. Since the Air Forces adopted this gun, they have "babied" it along, always demanding more in performance. Consequently, it has assumed the status of "standard" in fire power equipment. However, only through a long history of development has this gun attained this coveted position. Today, gunsmiths are still at work seeking new improvements.

The first machine gun was of Belgian ancestry and was developed as far back as the year 1851. The French at once obtained the piece, named it the "Meteailleuse," and placed it in service. A picture of this ancient model resembles a modern "Rube Goldberg" in design. The breechlock contained thirty-seven chambers which corresponded to barrels. The breechlock was set in place with its chambers loaded and locked into position. By turning a crank, the firing mechanism of the lock tripped, thus firing the cartridges. A rate of fire was quite unique, being solely dependent upon how fast the operator revolved the crank. Three hundred and seventy shots per minute could be obtained with a highly trained crew of men.

Gatling

The first practical machine gun was the invention of an American, Dr. Richard Gatling. His early model appeared in 1862 and it was not until 1912 that another type of weapon superseded his model. This early American gun had the same multiple barrel set-up as that of the first French variety. However, unlike the latter gun, these barrels were not stationary but revolved, and each barrel had its own firing mechanism. As the barrels were turned by an operator, they revolved past a hopper on the topside of the gun, with their breech open, thus allowing a cartridge to be chambered. The breech was then automatically closed, the cartridge fired and as the barrel continued to rotate, the breech was opened and the expended case thrown out of the breech. The barrels then were ready for the next round. As can well be imagined, people were skeptical of this Civil War invention. So much so, in fact, that Dr. Gatling was forced to lure his own gunners, train them for his gun and then send the piece with its operators into battle with the Union Army. Only in this manner could he prove the worth of his invention.

Maxim

The real "father" of the modern machine gun, as we know it today, was another American named Maxim. This inventor journeyed to England and while there became vitally interested in the further development of the machine gun. He set up a laboratory near London and soon produced the Maxim machine gun, which in time was to kill more men than any other weapon ever employed. This piece, for the first time, delivered a high rate of fire power over a long period of action. It required no extra assistance in operation. Simply pressing the trigger and feeding it belt ammunition were the only manual labor steps necessary for its functioning. The gun itself utilized a single barrel with a water-cooled jacket which had a stream condenser attached to it, so that the gun might be fired over a long interval without mishap. Another feature of the piece was the utilization of the recoil of the explosion to operate the gun and to introduce belt feed.

Browning

The next prominent figure to enter the scene in the development of the cal. .50 machine gun is John M. Browning. It is with him that we usually associate the modern gun. He took advantage of chamber pressure and let off part of the gases by drilling a hole in the barrel near the muzzle. Cooling the piece was effected by a water jacket around the barrel. The Browning gun saw wide, effective service in World War I with the Air Corps. As might be expected in aerial operations, a barrel jacket with water-cooling was not necessary.

THIS PAGE IS DECLASSIFIED IAW EO 13526

The firing bursts were short and the rush of air over the barrel was sufficient to prevent over-heating. The foremost machine gun of today is the famed American cal. .50 Colt-Browning. Strangely enough, this gun that proved itself beyond doubt in warfare against both the Germans and Japanese, was developed by the Germans during World War I. The present type fires a spitzer-type projectile, weighing from 753 to 800 grains, the heavier bullet usually being employed in air combat. This bullet leaves the muzzle at the rate of 2500 feet per second, and has a striking force of 10,765 pounds. The rate of fire is between 750 and 850 rounds per minute. The gun is cooled by a perforated jacket, which supports the barrel, thus increasing the accuracy of the piece. So much for the gun itself. A more thorough and comprehensive study of the gun will be made in this course.

Browning's name looms large in the history of weapons. He was a natural born gunsmith and at the age of thirteen designed his first weapon, a wooden model. Browning invented the majority of Winchester pieces, both rifles and shotguns, up to the time of his separation from that firm. He likewise developed the majority of the Remington line and all of the automatic pistols manufactured by Colt, yet his name was never connected in their production with the exception of military weapons. Browning's pieces have also been manufactured in practically every country of Europe. During World War I, Browning's machine gun was adopted over the Maxim and Vickers models because it was more reliable in performance, cost less to manufacture, and could be produced more rapidly. Other features of his guns are their simplicity of design and positive performance. The Army .45 automatic pistol was first produced in 1905. At first it failed to appeal to the Army Ordnance Board because it desired a more complicated specimen. Accordingly, Browning redesigned the piece to meet their ideas. No automatic gun ever invented will stand the abuse of the famous "Model 1911, U. S. Army." The first machine gun developed by Browning came into view in 1890 under the name of Colt. It was immediately accepted by both the Army and the Navy. The same gun was used in the Spanish War and in China during the Boxer

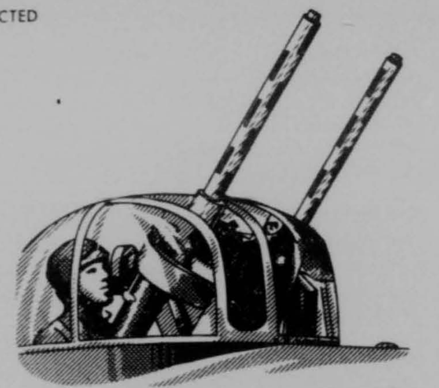

Figure 1—2. Topside. Twin Fifty-Caliber Colt-Browning Guns in a Power Turret on a B-25.

Rebellion. It was not until after the first World War that the present cal. .50 machine gun was brought on the market.

4. AIRCRAFT CANNONS

Machine guns are fast being replaced with aircraft cannons. Aircraft cannons are those in the range of 20 to 40-mm. The small bore cannon as employed by ground military forces are quite different from aircraft cannon. Years ago, before special cannon were developed for air combat, ground guns were merely adapted to airplane mountings without any attempt to redesign either the guns or the ammunition for the special requirements of aerial combat. The conditions which aircraft cannon had to meet were:

An exceptionally high firing rate for short periods of time.

A low weight of gun and ammunition.

The least possible recoil of the cannon.

A reduction of the size and primarily the length of the gun to facilitate mounting and manipulation while firing.

Fortunately, the very difference in the desired results in air and ground combat enabled gun designers and manufacturers to meet these requirements.

Out of these designs emerged the American 20-mm cannon. The 20-mm, 2,850 ft. per second automatic gun is a combination blowback and gas-operated aircraft weapon. The gun is air-cooled and has a cyclic rate of fire of 600

to 700 rounds per minute. It is designed for mounting as a fixed gun in the wing or fuselage of an airplane.

As early as 1933 the American Armament Corporation started developing a 37-mm fully-automatic cannon, specifically designed to be mounted on aircraft.

One model of this weapon may be mounted in the nose of the plane or in a gun turret in the body of the fuselage.

The B-25 and the B-26 have 75-mm cannons mounted in the noses of the fuselage.

The effectiveness of cannons is gradually being replaced by the use of rockets. The 4.5 rocket is equivalent to the 105-mm cannon in its destructive force.

5. THE ROCKET

A rocket is a missile propelled at high speed, by the rearward expulsion of gases generated by the combustion of an internally-carried fuel. It works in obedience to a natural law first recognized in the late seventeenth century by Sir Isaac Newton who propounded it, as the third of his laws of motion: for every action, there is an equal and opposite reaction. This will be discussed briefly here, but in more detail later in the course. The action of the gases from the burning fuel, in pushing rearward out of the rocket, is matched by an equally forceful reaction which pushes the rocket in a forward direction opposite to that of the flow of the gases. It is this reaction force which causes a rocket to fly through the air. It is not the push of the escaping gases against the atmosphere. A rocket can operate in a vacuum. In fact, the thinner the air the faster it flies, because there is less atmospheric resistance.

History

The rocket principle has been successfully incorporated in a number of mechanisms. The best known of these is fireworks. The rocket was first employed as a military weapon by warriors of Mysore, India, in fighting the British at Seringapatam in 1792. It has long been used as an instrument for signaling and as a life-saving device to carry lines from shore to stricken ships. It has found practical, scientific use in meteorological studies in carrying weather instruments to the highest altitudes. In the years between World War I and World War II extensive experimentation was carried on with rockets in Italy, Germany, and the United States, principally by experimenters banded together into rocket societies.

World War II

The rocket was introduced as a military weapon in World War II. Every major participant used it. Each nation developed this weapon in answer to its tactical and combat needs. The Russians pioneered in the firing of antitank rockets from planes, and in the use of massed banks of rockets for preassault barrages. The British used them for defense against attack from the air at a time when there were only five hundred antiaircraft guns in the United Kingdom. With their Luftwaffe driven from the skies, the Germans employed the long range V-2 weapon to attack England's cities. The Japanese unsuccessfully attempted to use rocket artillery to defend their island outposts. The United States, too, developed and introduced a great variety of rocket weapons. By the time the war ended, American soldiers, sailors, and marines had fired millions of rockets at the enemy. For this weapon, our armed forces could thank the team work of American science, industry, and the military at home. When the Japanese attack on Pearl Harbor catapulted the United States into the war, our Army and Navy had not a single rocket in service use and plans for their use were limited. By V-J Day, the Army was procuring rockets at a cost of $150,000,000 a year. The Navy had 1,200 war plants turning them out at a cost of $100,000,000 a month.

One of the most spectacular rocket weapons of the war was the German V-2. Allied technical intelligence provided information about the V-2 more than a year before it finally hurled out of the stratosphere to strike London. Our only countermeasure was to attack the launching sites with every means at our command. The Germans had been working on such a rocket since 1935. We had not. To start in 1943 to develop a similar American weapon would have required several years of intensive research on the part of our scientists in order

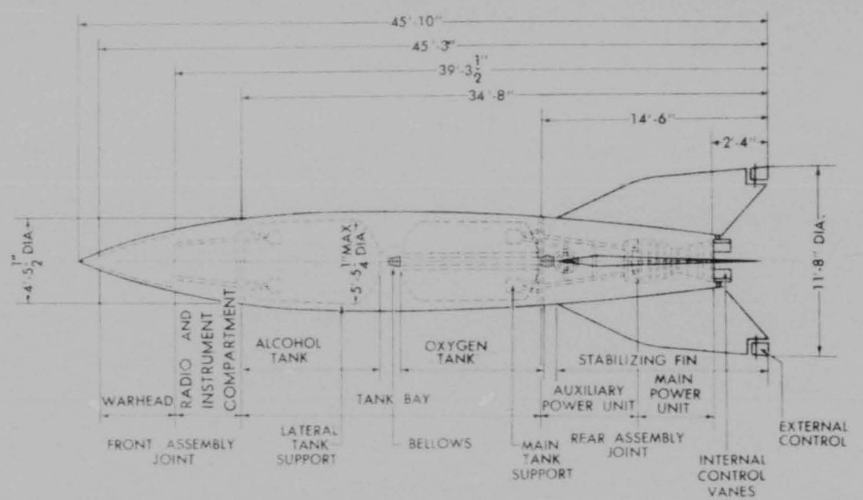

Figure 1—3. V-2 Bomb.

to provide the fundamental design data which German workers had accumulated over many years. The tactical importance of such a weapon to the Allies was not great enough to warrant the diversion of scientific manpower already thinly spread over a vast military research program which included the development of the atomic bomb. The American rocket workers, both military and civilian, had no store of basic data such as an adequate program of peacetime preparedness would have given them. The task of providing our fighting forces with rocket weapons would have been even more difficult and time-consuming if the British had not done experimental work with rockets before the war, and shared with us their knowledge and experience. As it was, the job was difficult. Every new project and improvement required an initial phase for the development of fundamental facts which a more complete program of peacetime military research would have developed in advance.

Their accomplishment is a tribute to the determination of the Army and Navy, to the imagination of American scientists, and to the productivity of American industry. Starting under a great handicap, they were able to produce the rockets which hunted down enemy submarines in the Atlantic and Pacific; the bazooka, first turned loose against the enemy in North Africa; the aircraft rockets which spearheaded the Normandy breakthrough in July 1944; and the barrage rockets which laid down a deadly fire ahead of our forces invading North Africa, Sicily, Italy, Normandy, and southern France.

6. GUN SIGHT AIMING POINT CAMERA

The present gun camera is essentially a small motor-driven, magazine-loading 16-mm motion picture camera, designed to be mounted near the sighting station of both fixed and flexible guns. In some cases it is mounted directly behind the gun sight to photograph the sight reticle as well as the target which is being fired upon. The use of gun cameras for the training of pilots in aerial gunnery and combat procedure dates back to World War I. It is believed that the first gun cameras were employed by the British and French sometime during 1915 or 1916. These cameras, though cumbersome and difficult to operate, proved their worth by more accurate and effective gunnery. Eastman Kodak Company produced the first American gun camera in 1918. Resembling a more advanced British gun camera, it simulated a cal. .30 machine

gun. It was powered by a spring-driven motor, wound before each mission, and used 35-mm film. A stop watch was incorporated. A picture of the watch was taken at the end of each burst fired, to eliminate disputes between the engaging pilots over who was accountable for the first vital "shot" which may have brought down his adversary's plane.

About 1938, these cameras were improved. They incorporated operation by electric motors, and with the improvements made in photographic lenses and film emulsions the 16-mm film replaced the 35-mm film with little if any change in the clarity of the picture.

Next came the magazine form of loading the cameras. The gun camera no longer took the shape of a machine gun as it was now operated by remote control and became a streamlined, cylindrical shape. This camera was the forerunner of the gun-sight aiming-point camera, an American invention, developed after a comprehensive study by Wright Field technicians. They sought to produce a new highly efficient piece of equipment better suited to the needs of aerial gunnery instructors. This gun-sight aiming-point camera will be discussed in greater detail in a chapter later in this course.

SECTION III—AMMUNITION

1. GENERAL

Fire power is measured in terms of amount of ammunition; that is, weight of ammunition that can be shot from a single gun or from all the guns of an airplane within a specified period of time.

This fire power must be delivered in a vital spot of the enemy aircraft if it is to be effective.

During World War I the stepped-up machine guns fired only about ten shots per second. To augment this lack of fire power, specialized ammunition quickly made its appearance. Accuracy was of prime importance because of this limited fire power. The ring sight was used, then the Aldis sight. Even with these aids the average pilot found it difficult to place every shot in a vital spot. Because of this, tracer ammunition was developed.

2. TRACER AMMUNITION

By observing the smoke trails and pinpoints of light, it is possible to ascertain the course of the gun's fire. Obviously useful, this ammunition is not without serious drawbacks. There is an optical illusion created at certain angles by the flame and the fire appears to be on the target when it is not.

In air fighting, the tracer has proved somewhat effective as an incendiary, particularly when gasoline tanks have been ruptured and free gasoline and fumes are present. The heat of the flame is sufficient to ignite the gasoline. However, against such targets as observation balloons widely used in World War I, the tracer proved a disappointment. The bullet would readily penetrate the envelope of the balloon but even sustained tracer fire bursts were not sufficient to ignite the escaping gas with any degree of certainty. As a result, another specialized type of ammunition made its appearance. This was the incendiary.

Incendiary ammunition of this type proved most effective against the raiding Zeppelins. Warneford, a British pilot flying an Avro, destroyed a Zeppelin over London the first time that this bullet was used against the raiders. It became certain death for the Zeppelins to be caught within range of these incendiaries. However, the use of this ammunition was restricted. Effective as it would have been against aircraft where the gasoline tanks were hit, it was not permitted to be used. Due to its "mushrooming" effect, it was classed as a "dumdum" and so banned by international agreement. When used against observation balloons, the pilots were issued written orders for the attack and these orders were carried with them during the course of the offensive action. If they were shot down during the attack, these orders covered the use of the ammunition and the pilots were not

THIS PAGE IS DECLASSIFIED IAW EO 13526

subject to execution as they would have been otherwise.

3. ARMOR-PIERCING BULLETS

Although protective armor as we know it today was not generally used during World War I, the value of armor-piercing bullets was early recognized. Hits with service ammunition on engines were not always effective. The bullets were, more times than not, deflected and slight damage resulted.

Due to the fact that this ammunition was of standard caliber, like all of the other specialized types, the size of the projectile was limited, and its effects were not sufficient to shatter an engine. It did, however, create damage which could cause engine failure. Against the heavy armor of tanks, this bullet was not effective. It lacked energy for penetration and merely embedded itself in the armor. The search for augmented fire power even led to the development of an explosive bullet of standard caliber. These bullets were actually nothing other than miniature shells. As a destructive agent the explosive bullet was not a success.

SECTION IV—TURRETS

1. GENERAL

Almost a decade ago it was foreseen that power-driven gun turrets would replace the open rear cockpit and open gun positions on large types of planes. The urgent necessity for providing an enclosed turret for the gunners was brought about by the increasing speed of aircraft. At two hundred miles per hour and more it became virtually impossible for the gunner to swing a twin-gun mount around. Increased number of guns per turret and larger weapons definitely forced the development of the power-driven, enclosed gun position. Among the early considerations for these turrets was the type of motive power that had to be accurate as well as sensitive, require little effort to operate, possess reserve power, and be comparatively light in weight. It had to be capable of smooth and instantaneously-variable speed from one direction of rotation to full speed in the other direction. In addition to rotation of the turret, controls had to be provided which would adjust the turret or gun mount in a vertical direction simultaneously with and also independent of horizontal motion.

Early Experience with Powered Turrets

The British were among the first to develop turrets successfully. The turret was mechanically controlled. But as hydraulic equipment came into being it was adapted to turrets. Then the turrets became fully electrical in their operation. These turrets were called local-control turrets because the gunner sat in the turret and moved with it.

Development of Remote-Control Turrets

Later came the development of remote-control turrets. These permit the best sighting positions on the airplane for the gunner, the best firing positions for the guns, and the most adequately protected position for the control mechanism.

A turret was even designed that was to be stabilized in azimuth and elevation. Then the pitch and roll of the aircraft would not affect the position of the turret.

SECTION V—GUN SIGHTS

1. GENERAL

The efficiency of fighter aircraft has been doubled as a result of the introduction of the compensating and computing gun sights. These sights take the element of guess out of aerial gunnery. The sights automatically figure the "fall" of the bullet because of gravity, the ballistic deflection caused by wind, and the amount of lead required to hit a target. Shooting from a fast-moving platform at a faster moving target makes the problem even more involved. These factors are also affected by air speed, density, and altitude. The sight compensates for these factors.

So far as the gunner is concerned, when using the automatic device, he seems to aim directly at the target. The sight, however, points the gun automatically and continuously at the spot where the target will be by the time the bullets arrive. The gunner makes no mental calculations.

Gun Sights with Radar

Today, gun and bomb sights work on radar. With this principle the gunner does not have to see his target visually. The invisible waves will paint a picture of the target on a screen before him. From the screen, he can determine when to fire the guns or drop the bombs.

SECTION VI—THE DEVELOPMENT OF AERIAL CHEMICAL WARFARE

1. INTRODUCTION

While customarily considered a new weapon of battle, chemical warfare is in reality one of the oldest of the arts of war. It should be understood that the term "chemical warfare," as applied to the ancients, deals almost exclusively with the use of incendiaries. Fumes and smokes were used, as such, at a much later date. No one knows when the first incendiary was used, or who first realized the tremendous power of fire as an agent of destruction. It appears reasonable to assume that the use of incendiaries commenced long before the record of man's activities was painted or carved on the walls of caves. It is entirely possible that the accidental igniting of dry grass demonstrated to the primitive people the great power of flame as an agent for driving game from cover into the open. This idea, first put into practice in the hunt, later may have been turned to advantage in the forcing of an enemy from his place of concealment or protection.

Fire Arrows

Herodotus records the use of fire arrows by Persian archers at the taking of Athens during the invasion of Xerxes in the year 480 B.C. This is the first written record of the use of this weapon on Greek soil. There are, however, Biblical references which trace the fire arrow back to the eighth century, B.C. That the fire arrow proved to be a valuable weapon is evidenced by the fact that it was still in use in the year 1860 when it was employed by the Chinese against the French.

Gas

Sulphur was used in war at an early date. This is borne out by the record of the siege of Plataea in the year 429 B.C. During this operation, the Spartans heaped fagots in the open space between the wall of the town and the inner fortification. These fagots were thrown from within the Spartan lines and after a great heap had been so deposited, balls of blazing pitch and sulphur were tossed onto

THIS PAGE IS DECLASSIFIED IAW EO 13526

the heap to ignite it. In his "History of the Peloponnesian War" the Greek writer Thucydides states that this operation would have been entirely successful if a sudden rainstorm had not extinguished the flames. Five years later the fortification of Delium was attacked in a somewhat similar manner. In this instance, an iron cauldron filled with glowing coals, pitch, and sulphur, was brought near to a portion of the wall that was of timber construction. A ship's spar was hollowed out to resemble a tube, and lined with iron. This spar was connected to the cauldron by means of an iron snout that extended from within the spar downward to the cauldron. A bellows was applied to the other open end and air forced into the cauldron, causing a great burst of flame and very intense heat. Thucydides relates that this machine was so successful in its operation that the wall of the fortress was consumed and the defenders driven away in panic. While pitch and sulphur were used in both of the foregoing operations, the accounts would seem to indicate their use as an incendiary only. They were not credited with any value as producers of stupefying and asphyxiating fumes. It is difficult to believe, however, that by the time of the siege of Delium the Spartans had not begun to realize in some manner the overpowering effects produced by the fumes of burning sulphur. It is entirely possible that this material was used in this latter instance as an asphyxiating agent as well as for its incendiary effect. Thus, we have examples of the early history of both incendiaries and asphyxiating agents as used in chemical warfare.

2. FUNDAMENTAL REASONS FOR CHEMICAL WARFARE

The instances of the early use or suggested uses for chemical agents are of little importance insofar as their effect on the science of warfare is concerned. They serve to show, however, that the introduction of chemical warfare in war was not accidental, but was due to fundamental causes; that its development parallels that of other forms of warfare. As the fortifications and natural defenses of the ancients became more nearly perfect in their protection against the existing weapons and means of defense, a situation of deadlock was reached; resourceful commanders searched for new weapons and means to overcome the protection. In this search, they naturally turned to the developments of peaceful pursuit. When firearms were introduced about the beginning of the fifteenth century, the protection afforded by fortifications decreased and warfare again took to the open. With this increasing mobility on the part of combatants, suggestions for the use of chemical agents declined until the increasing power of offensive weapons drove the defense to cover. With the underground system of defense of World War I, protection was obtained, but an impasse was reached. The offense could not go forward. Some practical means had to be found again to overcome the protection. The natural, logical thing was to find some weapon to reach down into the deep trenches and dugouts. Gases offered the ideal solution, and chemical warfare in its present sense was begun; for the first time in its history, all conditions necessary for its successful use were present. These conditions were: the availability of large sources of raw materials, the existence of a highly developed and efficient chemical industry with its training, and battle conditions resulting from a state of balance between the offensive and defense. Chemical warfare thus became effective.

Chemical Warfare Service

The Chemical Warfare Service, as created on June 28, 1918, by the President was an emergency organization to remain in force not longer than six months after the termination of the war emergency. In 1919, its continuance until June 30, 1942, was authorized. After consideration of all available information and data, and due, largely, to the recommendations of General Pershing and other leaders who had experience in France, Congress made the service a permanent component of the Army by the National Defense Act, as amended June 4, 1920. By this act the service is charged with the investigation and development of smoke and incendiary materials, toxic gases, and gas defense appliances; the research, design and experimentation connected with chemical warfare and its materials; the procurement and supply to the Army of all smoke and incendiary material, all toxic gases and all gas defense appliances; the operation of shell filling plants and proving grounds; the organization, equipment, training, and operation of special gas troops; the operation of necessary schools of instruction; the supervision of the training of the Army in chemical warfare, both offensive and defensive; and such other duties as the President may prescribe.

3. AERIAL CHEMICAL WARFARE

There is no record of chemical attacks from the air during World War I. Today, however, it has been demonstrated that the airplane provides the most effective method of disseminating the various types of chemicals by spray or by bombs. Early in 1936, the Italians used mustard gas in aerial attack upon the unprotected and untrained Abyssinian Army. This is the first record of aerial chemical spray being used in warfare. Attack aviation is particularly suited to the dissemination of chemical sprays and the laying of smoke screens for concealment. Where in World War I it was possible to subject only front line areas to chemical attack, in World War II any area over which strategy aircraft could fly was subject to chemical attack. Early in the war incendiaries were used by both the enemy and the allies. Germany dropped incendiary bombs on London; we in turn used incendiary bombs against chemical plants, refineries, oil fields, and similar strategic targets far behind enemy lines. Late in the war with the introduction of napalm, a gelatinized petroleum substance which was highly inflammable, attacks were made on smaller targets, such as moving columns of vehicles and gun positions. The methods of spraying and the equipment used in chemical warfare will be described later in the course.

SECTION VII—FUTURE TRENDS OF ARMAMENT

1. GENERAL

The immediate future in air warfare will show radical advances in the actual weapons, as well as changes in quantities of aircraft used in bombing attacks, in numbers of fighter escorts, and in new tactics and techniques of mass air raids and battle maneuvers.

The machine guns of old and those still in use today will be largely, if not wholly, supplanted with shell-firing cannon of various calibers, with rocket guns supplementing or even replacing them in some instances. The lower calibers of shell-firing cannon will be employed for turrets and multigun wing installations, and the higher calibers for the huge flying boats and flying fortresses, and as engine-mounted cannon firing through a hollow-propeller hub.

The fixed-wing cannon, together with the flexibly-mounted ones in turret-gun positions, will gradually become more effective as airplane speeds increase, and as more room is made available in which to mount the guns with greater ammunition loads.

2. ARMOR PLATE ON MILITARY AIRCRAFT

It is probable that improved armor-piercing shells will be employed in the future. They will have greater penetration to offset the increased use of armor plate on all types of military aircraft. Indeed, a seesaw struggle has been on, and may continue in the future, between the ordnance designers on the one hand and the steel men on the other. The latter are manufacturing better armor plate against which only guns of high caliber can be effective—calibers that already have run as high as 75-mm. Although three-inch shells, when fired from cannon mounted on airplanes, have been designed to have a shorter range and lower muzzle velocity than similar bore ground weapons, they nevertheless have a tremendous explosive effect once armor plate or other parts of the airplane are struck. Additional armor plate cannot be placed on airplanes indiscriminately, however.

Besides concentrating the armor protection around the gun positions, it may be possible to have this armor adjustable or rotatable. Since fire normally will come from the direction in which the defending airplane's own guns are pointed, armor plate that protects only in this direction will be quite sufficient. In some cases, small pieces of armor plate have been attached directly to the single, or twin, machine-gun mount so as to protect the gunner's head and chest. These pieces weigh but little and protect fully where most needed.

Future Armor Plating for Aircraft

Undoubtedly, the fighting airplane of the future will be a clever design, one which may employ a more or less universal type of construction. It may have interchangeable armament sections in order that a number of machine guns, or cannons, or bombs can be carried; it also may have replaceable armor plating so that for various combat missions the airplane can be either with or without the protective plating.

To eliminate the principal disadvantage of armor plating, that of added dead weight, the possibility exists that a system of droppable plates can be carried by aircraft. The purpose of this is readily obvious. While a bomber is carrying its load of bombs into enemy territory, and during the performance of its mission in locating the target and unloading the bombs, the armor protection would be available. Due to the bomb load, the speed of the bomber is somewhat reduced, as is its maneuverability. Once the bombs are released, however, the bomber is expected to return to its base with the greatest speed. Furthermore, armor plating may be so designed that it can be mounted on the outer surfaces of wings and fuselage, or over vulnerable inner parts of the fuselage. When released in a manner similar to bombs, flares, or droppable fuel tanks, a reduction of one thousand or more pounds may be effected and the bomber can return with the speed and maneuverability of its empty rating. This idea, carried through to development, appears to offer the answer to several problems at the same time: protection during operations over enemy ground, and the best speed and altitude performance of which the bomber is capable without its combined bomb and armor plating load after completing its mission.

3. AIRCRAFT ARMAMENT IMPROVEMENTS

Improvements in aircraft design, reflected in recent innovations in airplane structures, engines, and accessories, are being accompanied by numerous advances. These advances are in armament mountings, simpler and more efficient gun turrets, wings designed around a multiplicity of cannon, and a host of other changes destined to make an air force a more effective striking weapon against enemy air, sea, and land power.

New airplane types and new bombs will see future bombing deviate from practices now employed. Extremely low-level attacks may take place under more favorable conditions for the bombers; substratosphere bombing and fighting also is in the offing.

Dive bombing will be aided by the rocket bombs, already in limited use. After being released in a dive toward its target, the bomb is kept from following its natural trajectory by a propellent which sends it along a straighter path, resulting in greater accuracy. Incidentally, the airplane need not come down to such a low level in the dive.

The substratosphere will be the operational sphere of the huge military transports and bombers to come. Crossing continents and oceans, these battleships of the air will thereby keep out of sight and range of all ground defenses. They will be above all adverse weather conditions, and in general fly on their missions with the timing which only these conditions will permit. There will be air fleets moving in the upper air lanes, fleets of all the belligerents, if the war is to be of long duration.

The only defense against these armadas will be the fighters who can stay up at extremely high altitudes long enough for patrol duty and still be able to outfly and outfight the inherently-slower and less-maneuverable bombers and transports.

Substratosphere fighting airplanes must be detected long before they reach vulnerable objectives, and when so detected, must be destroyed or diverted from their missions. It is obvious that such a procedure will require not only great quantities of airplanes, but

hard-hitting, positive-acting weapons on them.

On the one hand, there is the huge bomber on which heavy defensive guns and armor plate must be increasingly incorporated, because of its importance both in capital value in cash and crew, and in its intangible but undeniable power of destroying enemy objectives. On the other hand, there are the interceptor fighters whose sole duty it is to intercept these bombers and knock them out of the air before they arrive at their targets. This also calls for weapons and methods of using them that will enable the fighter pilots to combat the huge bombers with confidence and on a more than equal basis.

Merely to increase the speed of airplanes is not enough. High speed is valuable for every military plane purpose. But when the specific moment comes, whether it is in level bombing, dive bombing, or attacking an enemy airplane with gunfire, the attacking airplane must either so lower its speed or reduce control of maneuverability so as to become vulnerable to the enemy, or continue at extreme high speed and lose the time and opportunity of careful aiming and prolonged firing. Despite the amazing rates of fire of which machine guns and cannon are capable, the actual number of bullets or shells which can possibly hit an airplane are few and far apart. The days of following an enemy airplane on his tail are gone. One burst of fire, usually a burst that is aimed ahead of the enemy airplane in some one direction, is practically all that can be expected in air battles between fighter planes. Despite a superiority in speed, fighters that attack large groups of heavily-armed bombers are also at a disadvantage because they have sufficient fire power massed against them to keep them out of range.

Whether offensive or defensive action is considered, the problems are identical, and the answer is similar. More and heavier guns will be built into airplanes, more ammunition per gun will be carried, and more armor plate installed. While acknowledging the extreme difficulties involved, it is expected that there will be developed new sighting apparatus that will positively correct for errors, and also new types of ammunition that will overcome the inherent faults of present shells with their deviations. For the large aircraft, timeable shells may be used, and thus add a new danger to fighter craft equipped with smaller weapons only.

Prophecies on Future Air Warfare

Contrary to the many fantastic prophecies that one may hear concerning future air warfare, it is not likely that in the next generation air staffs of belligerent nations will be sitting safely behind desks pressing buttons to actuate and control robot bombing fleets. However, there can be little doubt that automatic manipulation will play a more prominent role in any future war. To say that another war within the space of the next two or three decades would be totally destructive likewise seems a bit farfetched in the light of developments during World War II. Despite any assurance that total destruction may be avoided, air warfare has shown conclusively that the havoc which can be wrought demands the most earnest and serious efforts toward maintaining an enduring peace.

4. DUPLEX PROJECTILES

In the weapons that comprise either aircraft or antiaircraft armament, including machine guns, small-caliber rapid-fire automatic cannon, as well as heavy antiaircraft artillery, the final word as far as results are concerned depends on the ammunition used. After all, it is the projectile itself that brings down the enemy airplane. True enough, the guns must be accurate, mountings secure and flexible, turret bases precise, but the projectile that whines through space on its way towards an enemy must have two primary characteristics: it must have accuracy; it must have high velocity.

Both rotational and transverse velocities of projectiles can be made to vary by adjustments in the gun itself. For example, it is possible to obtain higher spin by varying the length of barrel, or by making the barrel smaller than the ammunition and thereby forcing the ammunition through it. Adjustments also can be made by adding more propellent material in the cartridge or shell case. This gives added power and range.

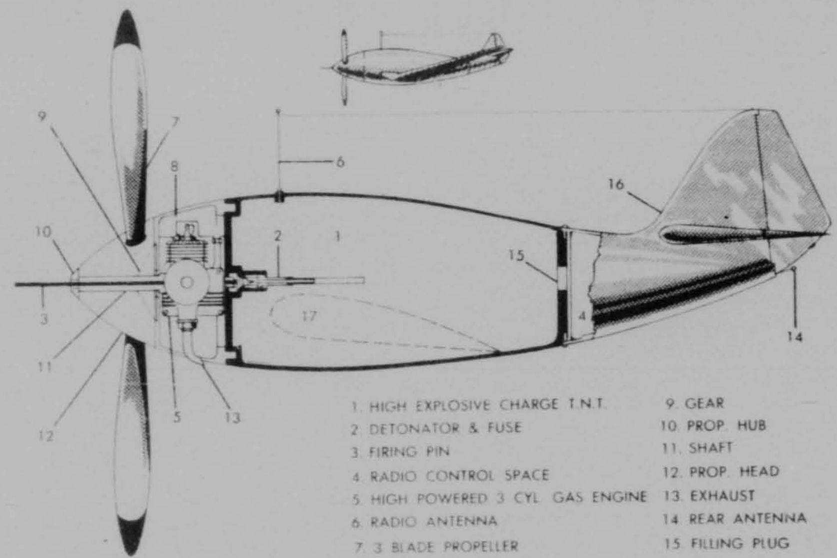

Figure 1–4. Radio-Controlled Robot Plane.

Projectiles in Flight

Before going into a description of an unusual type of projectile that combines accuracy with exceptionally high velocity and long range, it might be well to examine briefly the conditions that exist for projectiles in flight.

It is known that machine gun bullets have an initial velocity of about 2,700 feet per second (compared with the speed of sound, 1,100 feet per second). Yet it is amazing how greatly this velocity is progressively reduced by the resistance of the atmosphere. This resistance is affected not only by the shape of the entering form of the projectile, but also by the form of the trailing mass as it sets up turbulence behind the bullet.

The compressibility of air at velocities above that of sound has brought about the development of contours commonly known as "streamlining"; in other words, an extremely-pointed entering shape to overcome the impact resistance offered by the atmosphere. However, as the initial velocity is reduced and approaches the speed of sound, the turbulent air currents at the rear of the projectile become of increasing concern. Experiments are being conducted in an effort to solve the problems of turbulent air currents.

5. PRECISION ROBOT AIRPLANES

One of the most startling possibilities in future air warfare appears to be the development of radio-controlled robot airplanes that can accompany heavy, long-range bombers to their distant objectives. Large bombers, despite their numerous gun stations and heavy armament, are always vulnerable to numerically superior and faster enemy fighter aircraft because they are of themselves slower and more cumbersome. Fighter aircraft cannot accompany them on distant missions because the normal fuel capacity of fighters is limited.

Radio-controlled Planes

As part of the bomb load, these huge flying fortresses could each carry one or two tiny radio-controlled planes. These miniature planes would have folding wings so that they could be stowed away in the fuselage of the larger mother ship, the two airplanes being staggered to fit with the least possible interference into the faired-away interior. They would have small and inexpensive engines fed from fuel tanks of rather small capacity, since their radius and duration of action would be intentionally limited. They would carry a gyro pilot, controlled by a robot mechanism activated by radio impulses transmitted from the mother plane. They also would carry several bombs and smoke-screen gas tanks. The bombs could be detonated by radio.

In no branch of aerial warfare has there been any weapon exhibiting the versatile possibilities of these radio robot planes. They could be hung upon special hooks within the fuselage and the crew could lower them through the fuselage doors, open and lock the wings, start the engine, check the radio control, and release them for free but controlled flight within the visual range of the radio control operators. Carrying their timetable bomb load, they could be directed into formations of enemy aircraft to create havoc among them; they could be used to divert and prevent attacks upon the bombers themselves. They could be sent into enemy ground objectives with more accuracy and with less danger to the bombers than any precision-aimed, free bomb drops. They could precede or surround the bombers they protect, sometimes emitting smoke screens to confuse enemy aircraft.

Since they could not be retrieved, and since they should always destroy themselves with their deadly cargo, they may be constructed of nondurable materials. Being small and light, they could be produced in huge quantities at comparatively low cost. They would represent an enormous "suicide force," which would not risk a single life of the operating forces. While they could be adapted equally well to protect shipping when operated from surface vessels, their greatest all-round use would be as bomber-based flying bombs.

Radio-controlled Bombs

Unlike the robot planes and bombs previously described in the chapter on self-propelled ammunition, this particular radio-controlled bomb would have several unique features differentiating it sharply from long-range robot planes controlled by set mechanisms. The latter must have sufficient instruments to detect, correct, and compensate for variations in air density, winds, and course changes caused by exploding antiaircraft shells. Being controlled within the limits of visual range from mother aircraft (these limits may extend up to a hundred miles under good weather conditions if observed through high-powered glasses and if equipped with smoke-trail apparatus), the flying bomb is not a robot in the sense of those that are launched with pre-set controls. If anything, it becomes more of a precision bomb than those which are dropped in free flight and over which no further control can be exercised.

Essentially, this radio-controlled bomb could be made in three sections which could be nested into each other for final assembly. The forward section, or nose, could contain the small compression-ignition engine, together with fuel tanks and propeller. Due to their short range action, fuel tanks would be relatively small. The center section would be the actual bomb containing the explosive, which could be detonated either through the firing pin extending through the forward power section past the propeller spinner or by means of radio through a detonator operated from the rear section. The rear section would carry the radio receivers connected directly to tail-surface controls. Connecting rods, cables, and wires, therefore, would be direct and short. The wings would set into special recesses and hooks on the center section.

While controllable bombs of this type would cost more than free drop bombs of similar weight, they might, in all likelihood, reduce heavy bomber losses because the latter could remain well away from the target area in any direction.

6. ULTRAHIGH-SPEED GUN

Endeavors to improve existing weapons,

THIS PAGE IS DECLASSIFIED IAW EO 13526

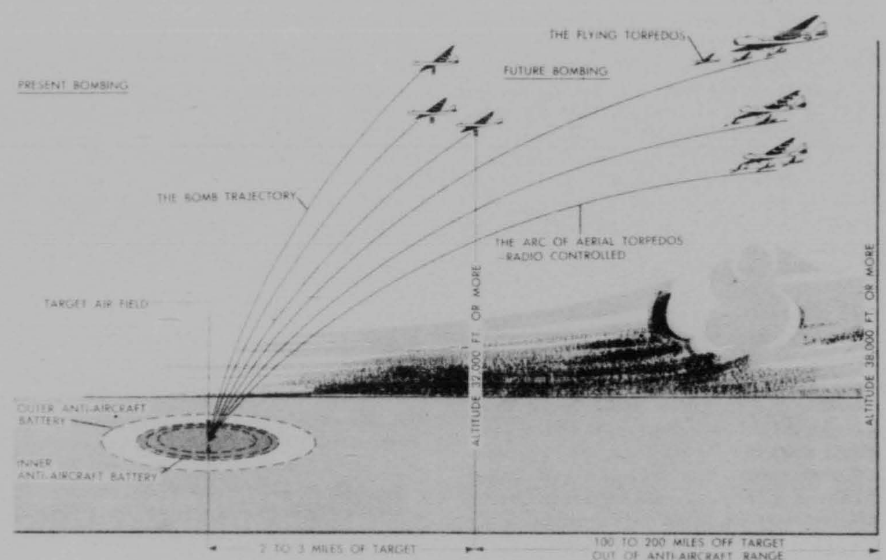

Figure 1—5. Present and Future Bombing by Radio-Controlled Aerial Torpedoes.

particularly from the standpoint of fire power, may lead to the time when even 20-mm cannon can be made to fire at a cyclic rate of several thousand rounds per minute. With the ultra high-speed gun regarded as a theoretical possibility, some predictions as to how the problems involved may be surmounted would seem to be in order.

The principal deterrents to actual construction and operation have been the difficulties in designing simplified feeding and firing mechanisms, and a gun barrel that would withstand the tremendous overheating and erosion from what would be tantamount to a continuous stream of steel through it. Such barrels, unless made from hitherto unknown metals, could last but a few minutes of total firing time and probably would have to be replaced after every flight.

It may be possible that high-speed cooling means can be evolved for these "stream" guns. Successful methods have been developed in which small-arms ammunition actually cleans the gun barrel during firing. Perhaps a system of changing or switching barrels in flight may be invented. Obviously, such schemes entail increased weight to the airplane due either to barrels or excessive amounts of ammunition.

Rocket Guns

The rocket appears to have the edge in future air armament. The high speed of the heaviest of bombers, combined with the amount of armor plate and other protective means they can apply to prevent damage from ordinary gunfire, point to the definite necessity of rocket guns and shells of naval-gun proportion being developed. Progress in this

direction is being made at this time. The primary disadvantage of rocket projectiles is their size. While deliberately made in large calibers for great explosive effect at the target, they also have to carry their own propellent material. A rocket equivalent to a 20-mm armor-piercing shell would be several times larger than the latter. This precludes a high-speed firing of such rockets since special feeding mechanisms would have to be designed. In conventional guns, as generally known, the force of recoil or the expansion of the propellent gases serves to operate the feeding of ammunition from belts or drums.

Conceivable Improvements in Automatic Guns and Ammunition

By the same token, it is conceivable that automatic guns and ammunition may be in for improvement by the adaptation of a principle used by the military a century ago. This will be illustrated in subsequent paragraphs outlining the author's conception of a possible aircraft or antiaircraft gun capable of being fed thousands of rounds of ammunition per minute.

From an airplane armament standpoint, the weight of cal. .50 bullets and small caliber cannon shells and the space required to carry them are still serious problems. One way of reducing the weight, and at the same time enabling several times the present amount of ammunition to be carried, would be to do away with the complete round by using the actual bullets or shells without the cartridge or shell cases. In effect, this would represent a return to the principle of separate-loading ammunition for small arms.

Gun chambers and feeding mechanisms for bullets alone could be less complicated mechanisms than at present required. No cartridge-case ejection mechanisms would be necessary. Firing rates conceivably might be stepped up to two thousand or three thousand rounds per minute cyclic rate. The propellent might be fed separately in special pellets, the container of which would be consumed within the firing chamber. Still more preferable would be a method of automatically feeding the propellent mixture through a flexible, armored pipe line directly into the chamber. The required amounts of propellent would be passed into the chamber behind the bullet or shell through a combined vacuum and pressure system used in conjunction with a mechanism that would effectually seal the chamber from the propellent feed line. The action of the gun itself, or possibly auxiliary pressure sources, could be made to clear a safety area behind the propellent cutoff after each bullet or shell had been fired. Possible, too, in such an arrangement would be a means of either manually or automatically controlling the amount of propellent while the gun is firing, which in turn would affect the firing rate, range, and gun barrel wear.

Firing could be done electrically. The problem then becomes one for the metallurgist and chemical engineer to consider. The tremendous heating of rifled gun barrels requires either a positive means of rapid and constant cooling, or a radical departure from conventional rifled barrel and ammunition design.

A striking solution to this problem is offered by a nonrotatable projectile which might be fired from conventional-type guns with smooth bores. Such a projectile was patented in 1930 by Peter Van Essen, of the Netherlands, and is covered in U.S. Patent No. 1,742-836. The patent is worth while studying as this projectile may have significant application in the future.

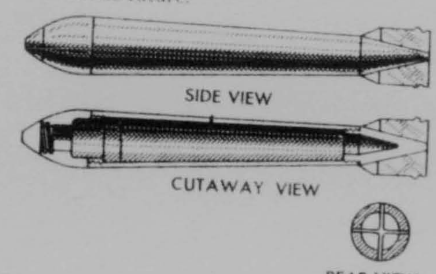

Figure 1—6. Van Essen Projectiles.

Van Essen's projectile is of such shape that the chamber pressure in the gun may be applied to a substantially large surface thereof, thus avoiding customary rearward thickening of the walls in a projectile of so-called normal design. Another object of the invention is to provide a projectile adapted to be fired effectively under wide variations in the angle of

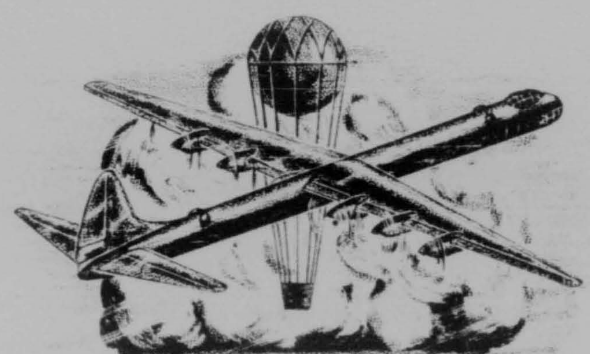
THIS PAGE IS DECLASSIFIED IAW EO 13526

elevation, without relying on its rotation about its axis to retain its position along the trajectory.

Experience has shown that rotating projectiles fired at high elevations drift out of their normal position tangential to the trajectory. This deviation impairs the proper functioning of direct impact fuses, and also results in a deepened dispersion zone and loss of concentration on the objective. The use of wind vanes, as a means of correction, is effective only at the expense of the remaining energy of the projectile.

The conditions are still more difficult in the case of projectiles having no initial rotation, as, for example, those fired from smooth-bore guns. While admitting the virtues of having the center of gravity as far forward as possible, and the stabilizing influence of wind vanes and similar contrivances, a further disturbing factor is introduced. This is the influence of gas pressure immediately after the gas checking portion of the projectile has left the muzzle of the gun. This pressure may cause a deviation of the axis of the projectile from its proper trajectory; the deviation may be further aggravated by the fact that the projectile is not rotating.

This new method of construction provides a projectile substantially nonrotatable about its axis and having the known advantages of a forwardly-placed center of gravity and corrective wind vanes. However, by tapering the body of the projectile rearwardly and providing centering means at the rear of the tapered body, a gradual release of gas pressure is effected while guiding or centering the projectile until it has been substantially released. By these means it is possible to obtain accurate and effective firing even at high angles of elevation, and to reduce substantially the depth of dispersion usual in ammunition of this type. New devices are under constant study in order to maintain the highest standards of armament.



CHAPTER 2—TECHNICAL PUBLICATIONS

SECTION I—DEPARTMENT OF THE ARMY PUBLICATIONS

1. INTRODUCTION

Prior to the armed service unification in 1947, the USAF was a part of the Army. Up to this time all the publications dealing with policies, orders, instructions, and information issued by the Army were applicable to the Air Force. Now that the Air Force is a separate department it is issuing its own publications. However, many issued by the Army are still applicable to the Air Force.

Since this condition exists, it is necessary that every Air Force officer learn the different types of publications that are issued by both the Department of the Army and the Air Force.

Note: Not all the publications will be discussed in this section, but only those that are of importance to the armament officer. Also the publications that pertain to supply matters will be discussed in the section titled "Armament Supply."

One of the primary duties of an armament officer is the proper maintenance of armament equipment.

Efficient maintenance requires that operating and maintenance personnel have available and properly use the latest technical information and operating directives applicable to their work.

Complete maintenance information is available in existing publications, therefore, technical libraries will be established and should be used to the maximum extent.

In general, the information and instructions applicable to maintenance of the technical services will be contained in Department of the Army publications. Information for the Air Force equipment and supplies will be contained in the Department of the Air Force publications.

There are other publications which are general, tactical, or administrative in nature rather than technical. These publications will be published by both the Department of the Army and Air Force.

Rather than explain these publications as to technical, tactical, general, or administrative nature, this section will list the publications that are issued individually by the Department of the Army and the Department of the Air Force.

Only by constant use of these publications will it be possible to understand the information contained in each. Many of these publications are interrelated as some may supplement others.

2. ARMY REGULATIONS

Army Regulation 1-15 gives the general provisions of Army Regulations. The following quotes from AR 1-15 are included as an example: "Within their scope they have the force and effect of law to the Army and those whom they concern and are binding and conclusive." "Army Regulations are the primary administrative regulations for the government of the Military Establishment." Administrative regulations and closely related material appear also in other forms, some of which are as follows:

Circulars, Memorandums, and Letters. Administrative regulations of wide but temporary application appear in circulars. Regulations of more permanent nature are also frequently published in circulars pending their incorporation in AR's or changes to AR's. Regulations of limited application are published in memorandums and letters.

The "Index of Administrative Publications" is found in Special Regulation 310-20-5.

Reference tables and explanations of detailed procedures to aid compliance with administrative regulations are published in:

Field and Technical Manuals (FM and TM)

Field Manuals (FM) constitute the primary means of promulgating the basic doctrines of military training and operations. They contain training instructions relative to tactics and techniques (Figure 2-1).

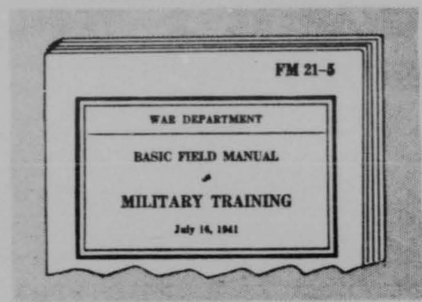


Figure 2—1. Military Training (FM 21-5).

Technical Manuals supplement Field Manuals, covering subjects the separate treatment of which is considered essential to a full accomplishment of the training prescribed in the Field Manuals. These manuals also describe materiel and contain instructions for the operation, care, and handling of equipment of the technical services. The instructions on any given item of equipment are published in manuals as follows:

Operator's Manual. For use of the arms and services. This covers only the operating instructions and such maintenance operations and procedures as are performed by the using organizations.

Service Maintenance Manual. This covers all the operations and procedures which are performed by field and base maintenance and includes the technical information necessary for disassembly, reassembly, and rebuilding of the item. Operator's Manuals and Maintenance Manuals are sometimes published under one cover as combined operation and maintenance manuals.

Technical Manuals are also guidebooks for instructors and specialists; they contain material for extension courses; reference books; administrative materials, supplementing Army Regulations; and similar specialized subject matter.

An example of a Technical Manual is illustrated below (Figure 2-2).

Field and Technical Manuals are numbered according to a single comprehensive system. Each manual carries a basic number (the first

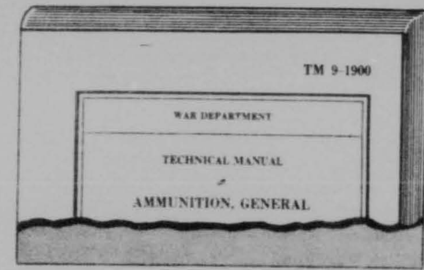

Figure 2—2. Ammunition, General (TM).

number) and a subnumber (the second number). The basic number identifies the subject matter to which the manual applies. The subnumber is a further means of identifying the publication within its particular class.

Basic Number. Examples of basic numbers that are allotted to subject matter follow:

1. Air
3. Chemical Warfare
9. Ordnance
23. Basic Weapons
38. Supply Procedure

Subnumbers up to 199 are assigned to Field Manuals; subnumbers 200 and higher are reserved for Technical Manuals. For example:

8-5 is a Field Manual in the Medical series, the basic number is 8 indicating Medical and the subnumber 5 showing that it is a Field Manual.

8-233 is a Technical Manual in the Medical series, the subnumber 233 indicating that it is a Technical Manual.

3. TECHNICAL BULLETINS

New instructions and information regarding maintenance operations and procedures may appear as Department of the Army technical bulletins prior to publications in a Technical Manual or change thereto and are subject to rescission when incorporated in new publications.

Technical bulletins will not contain material pertaining to tactical training or tactical operations.

Technical Manuals are numbered as explained below:

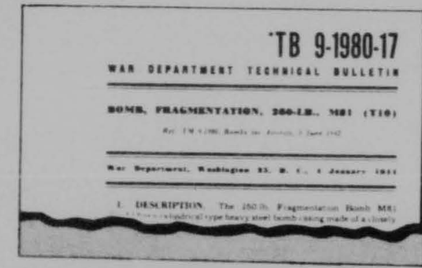

Figure 2—3. Bomb, Fragmentation, 260 lb. (Technical Bulletin).

Bulletins pertaining to Technical Manuals bear the number of the manual with an added serial number to differentiate one bulletin from another on the same subject. Example: TB 9-1980-17 indicates the seventeenth technical bulletin which affects TM 9-1980 (Figure 2-3).

Bulletins which do not pertain to a single Technical Manual bear the abbreviation of the originating service and are numbered consecutively. Example: TB CW 25 is the first Chemical Warfare technical bulletin not directly pertaining to a single technical manual (Figure 2-4).

4. TRAINING CIRCULAR (TC)

Training circulars are designed to promulgate—

New training doctrine.

Training doctrine, tactics, or technique, the immediate dissemination of which is essential.

Training policies or information of temporary nature or not relevant to the scope of existing manuals.

Training circulars are numbered in consecutive series for each calendar year.

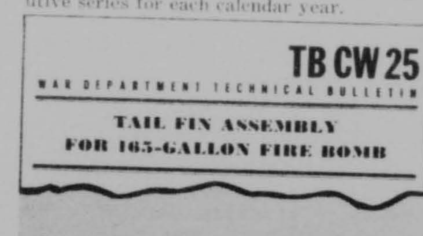

Figure 2—4. Tail Fin Assembly (TB CW).

THIS PAGE IS DECLASSIFIED IAW EO 13526

5. LUBRICATION ORDERS

Lubrication orders are illustrated, numbered, and dated cards or decalcomania labels which prescribe organizational lubrication instructions for mechanical equipment. They will be carried with, or attached to the equipment to which they pertain: instructions contained therein are mandatory.

6. MODIFICATION WORK ORDERS (MWO)

They provide authentic and uniform instructions for the alteration and modification of United States Army equipment.

For additional information on the explanation and scope of the Department of the Army publications see AR 310-20. DA Circular 41, 1949 makes the following changes:

Publication Indexes

The last edition of FM 21-6 to be published and distributed is dated 1 January 1949.

In the future the indexes of publications and blank forms now published in FM 21-6, AR 1-15, and AR 1-10 will be published in the following Special Regulations:

SR 310-20-3. Index of Field Manuals, Training Circulars, Firing Tables and Charts, Graphic Training Aids, Army Training Programs, JANAP's, Combined Communications Board Publications, Tables of Organization and Equipment, Tables of Allowances, and Tables of Basic Allowances.

SR 310-20-4. Index of Technical Manuals, Technical Bulletins, Supply Bulletins, Lubrication Orders, and Modification Work Orders.

SR 310-20-5. Index of Administrative Publications (Army Regulations, Joint Army-Air Force Adjustment Regulations, General Orders, Bulletins, Circulars, Commercial Traffic Bulletins, Joint Procurement Circulars, and Department of the Army Pamphlets.

SR 310-20-6. Index of Blank Forms and PRT's.

SECTION II—DEPARTMENT OF THE AIR FORCE PUBLICATIONS

1. INTRODUCTION

Department of the Air Force official publications will provide, insofar as practicable, all the information needed by individuals and elements of the Air Force in the performance of official duties. Air Force Regulation 5-5, titled "Department of the Air Force Publications," prescribes the types of publications issued by the Air Force. Distribution formula for Department of the Air Force publications is prescribed in AFR 5-4.

Following is a list of the publications an armament officer will be concerned with in the performance of his duties.

Note: Publications issued by the Air Force that concern supply primarily will be discussed in this manual under the title "Armament Supply."

2. AIR FORCE REGULATIONS (AFR)

Air Force regulations are the primary administrative regulations for the government of the Air Force and contain directives, policies, and administrative instructions of permanent and wide application. They are binding and conclusive upon the Air Force and those whom they concern.

3. AIR FORCE LETTERS (AFL)

They contain matter that is directive in nature, general in application, but temporary in duration.

4. AIR FORCE MANUALS (AFM)

Air Force regulations requiring voluminous detail may be augmented by Air Force Manuals.

Figure 2—5. Publications (AF Regulation).

The Numerical Index to AF Administrative Publications is AFR 5-2 (Figure 2-5).

Publications issued by the Air Force which provide technical instructions and information pertaining to the operation and maintenance of Air Force aircraft and equipment are referred to as "technical publications."

5. AIR FORCE TECHNICAL PUBLICATIONS

General

When a person buys a new commercial appliance, car, or other mechanical contrivance, a little folder of operating and maintenance instructions is usually furnished by the manufacturer. These instructions are supplied in order that the user may obtain the greatest possible satisfaction from his purchase. The manufacturer goes to considerable work and expense to provide the user with printed information about his product.

In the same way, the Air Force is vitally interested in seeing that its equipment functions properly and is maintained as efficiently as possible. It is a tremendous task to see that all of the various types of Air Force equipment, including the new gigantic aircraft, the engines, the radio and radar equipment, and all the other types of items necessary for the successful operation of a world-wide air force, are operated and maintained efficiently and economically.

The Air Force, like the manufacturer of a commercial appliance, provides printed instructions for use in connection with its equipment. These printed instructions, i.e., manuals, handbooks, sheets, charts, etc., which provide technical instructions and information pertaining to the operation and maintenance of Air Force aircraft and equipment, are referred to as "technical publications." They are published and distributed by the Air Materiel Command for and in the name of the Secretary of the Air Force, in accordance with AF Regulations 5-1, 5-10, and 20-1.

With so many types of equipment affected, it can be readily understood why there must be a technical publications system, a well organized and planned procedure whereby information is obtained, compiled, published, and distributed to the particular Air Force activity which needs it. Years of experience have resulted in the adoption of the standard system outlined below (See Figure 2-6).

THIS PAGE IS DECLASSIFIED IAW EO 13526

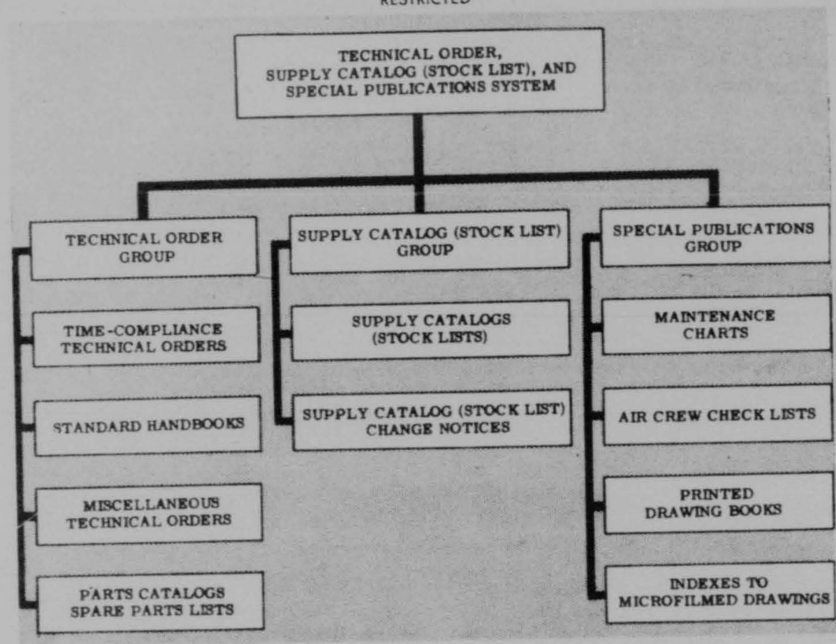

Figure 2–6. Major Groups and Types of Publications.

Major Groups

Three major groups, comprising appropriate types of publications, form the standard Air Force technical publications system. (See Figure 2-6):

Technical Orders (including applicable Air Force-Navy [AN] publications).

Supply catalog (stock list) publications.

Special publications.

Technical Orders, including Air Force-Navy (AN) publications and supply catalogs, normally are issued on loose leaf pages of standard size (8½ x 11 inches) to permit convenient assembly in uniform binders and placement in the prescribed technical publication files.

Special publications are issued in varied forms and sizes, depending on the intended usage. These technical publications normally supplement or implement the information and instructions. Typical examples of publications belonging to this group are the aircrew check lists and Air Force maintenance charts.

6. TECHNICAL ORDERS

The first of the three groups of technical publications includes Air Force technical orders, including Air Force-Navy (AN) publications which comprise a comprehensive group of publications issued to furnish Air Force personnel with general technical information on the use and operation of Air Force aircraft, equipment and accessories, and specific operating, maintenance, overhaul, repair, modification, storage, issue and inspection information on particular items of aircraft and equipment.

Instructions and procedures contained in Technical Orders are official Air Force directives and must be complied with as prescribed therein. Technical Order publications are readily identified by the prefix "T.O. No." to the assigned publication number.

Note: For purposes of uniformity and clarification, the term "technical order" when used in this publication embraces all publications bearing the aforementioned "T.O. No." prefix.

Air Force-Navy (AN) publications are published by joint agreement of the Air Force and the Navy Bureau of Aeronautics. The prefix "AN" indicates that the publication was prepared in accordance with Air Force-Navy aeronautical specifications. When applicable to Air Force aircraft or equipment, AN publications will be regarded as being identical in purpose with AF Technical Order publications.

Types of Technical Orders

The Technical Order group of publications consists of the following four general types:

Time-compliance Technical Orders.

Standard handbooks.

Miscellaneous Technical Orders.

Parts catalog (including spare parts lists).

A specific numbering system is employed to identify all publications belonging to the Technical Order group. The numbering system used is illustrated in the Table of Contents of T.O. 00-1-1, "Numerical Index of Technical Publications."

When only small quantities of equipment are purchased for Air Force use, commercial publications issued by the manufacturers sometimes are accepted in lieu of standard handbooks and parts catalogs. These commercial publications are given Technical Order numbers and are available only to activities operating or maintaining the equipment involved.

Time-compliance Technical Orders

Purpose. Publications of this type require compliance within specified time limits and provide for modifications of Air Force aircraft and equipment or furnish supplementary instructions covering inspection and operating procedures. In many cases time-compliance technical orders contain specific instructions for operating personnel; in such cases, commanders will be responsible for insuring that operating personnel become familiar with the contents of publications of this nature.

Types. Time-compliance Technical Orders are grouped according to the importance and urgency of the instructions contained therein. Notes are employed immediately preceding the text to specify when and by whom compliance will be effected and the degree of urgency. Time-compliance Technical Orders include the following types:

Immediate action Technical Orders.
Immediate attention Technical Orders.
As soon as possible Technical Orders.
As soon as practicable Technical Orders.

Format. Time-compliance Technical Orders are published without a title page under the heading "Department of the Air Force, Headquarters, United States Air Force, Washington," and bear the closing phrase "By Order of the Secretary of the Air Force." Borders or identification notes printed in red are used to focus attention on the more urgent time-compliance publications.

Immediate-action Technical Orders. Immediate-action Technical Orders are identified by the use of a border of red "X's" and the words "Immediate Action" printed in red. The border indicates that a red "X" must be entered in the "status today" columns on AF Forms 1-A, 1-AG and 41B. Immediate-action Technical Orders contain emergency instructions applicable only to aircraft and aircraft components, the urgency of which is such as to require the immediate grounding of the aircraft pending compliance. They specify that the work outlined therein is to be accomplished immediately. Such Technical Orders do not contain instructions of a continuing nature, such as a requirement for subsequent periodic inspection. The publication of immediate-action Technical Orders is expedited by HQ AMC as the instructions contained therein are of vital importance. Such Technical Orders will be disseminated to all affected personnel without delay.

Immediate-attention Technical Orders. Immediate-attention Technical Orders are readily identified by the words "Immediate Attention" printed in red at the top and bottom of the first page. They are similar to immediate-action Technical Orders except that they normally do not require work, except placarding for the pilot's information or marking of flight instruments. When applicable to aircraft, these Technical Orders contain important informational, operational, precautionary, and restrictive instructions on conditions which seriously affect the safety of flight of the aircraft involved, but which do not require its grounding.

Immediate-attention Technical Orders are also used for extremely urgent modifications or inspection instructions pertinent to personal equipment, chemicals, vehicles and other items of ground and communications equipment, as an immediate action category bears no "grounding" significance when applied to such equipment. The publication of immediate-attention Technical Orders is expedited by HQ AMC as the instructions contained therein are of vital importance. Such publications must be disseminated to all affected personnel without delay.

As-soon-as-possible Technical Orders. As-soon-as-possible Technical Orders are printed with a border of diagonal red lines which indicates that a red diagonal must be entered and carried in the "status today" columns on AF Forms 1A or 1AG and 41B until compliance has been effected. These Technical Orders provide instructions pertaining to aircraft and components and specify compliance as soon as possible but not later than a specified inspection period. Such Technical Orders normally require correction of defects affecting the flying efficiency of aircraft which are not sufficiently urgent or dangerous as to warrant grounding the affected aircraft. Compliance with this type of Technical Order is necessary before the aircraft can be considered to be in first class mechanical condition. Pending compliance with such Technical Orders, an "exceptional release" is required to clear the aircraft for flight. Such publications must be disseminated to all affected personnel without delay.

As-soon-as-practicable Technical Orders. As-soon-as-practicable Technical Orders contain instructions which specify that the work to be accomplished may be performed within broader time limits than those specified for the more urgent classes of time-compliance publications. They require compliance when accomplishment will not interfere with flying schedules, unless local conditions necessitate more urgent action, or when the affected aircraft or equipment is undergoing overhaul or other repairs. This type of Technical Order contains instructions to remedy defects that are not necessarily serious, but which must be corrected to forestall possible future malfunctioning or failure. They currently bear no distinguishing format or symbols to afford ready identification and can be identified only by reading the compliance requirements appearing beneath the titles.

Other Types. In some instances, Technical Orders are published to provide instructions for modification of equipment; they may cover the installation of special equipment; they may deal with equipment for the performance of special duties and missions which are not normally made by all aircraft or equipment of the same model or series. Compliance, in such instances, is effected only upon issuance by Hq., Air Materiel Command, of additional instructions directing the work to be accomplished on specific aircraft or equipment. Such Technical Orders can be identified only by reading the compliance requirement beneath the title (Figure 2-7).

Standard Handbooks

Purpose. Publications in this group contain basic instructions and information relating to operation, service, repair, and overhaul of Air Force aircraft and equipment.

Format. Standard handbooks are usually prepared by the equipment manufacturer in accordance with Air Force-Navy (AN) or AF specifications. These handbooks normally are issued with a full size title page bearing the assigned "AN" or "T.O." publication number, with the word "HANDBOOK" preceding the title. When a full size title page is used on a standard handbook, it is backed with a basic "A" page, followed by a series of pages numbered in lower case Roman numerals (i, ii, iii, etc.) containing the table of contents and illustrations of the equipment covered in the publication. In cases where the material in a

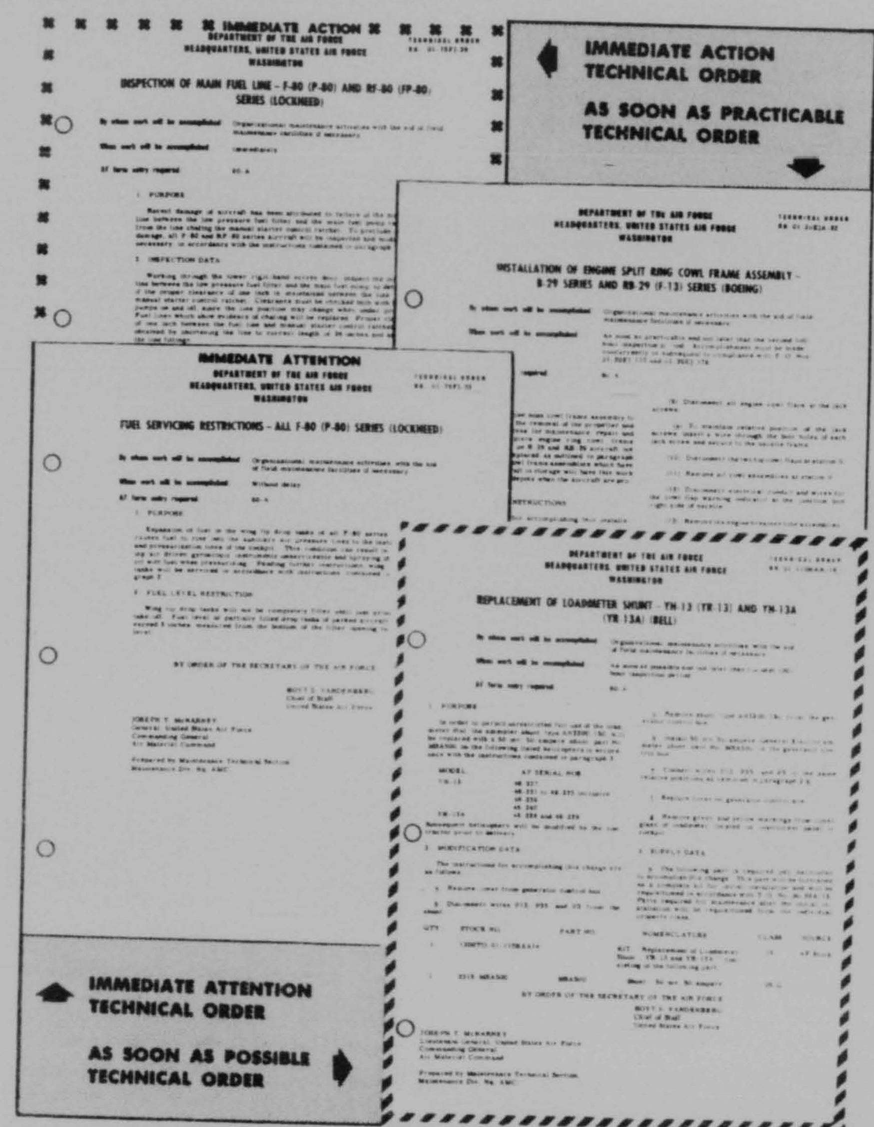

Figure 2-7. Time Compliance Technical Orders.

THIS PAGE IS DECLASSIFIED IAW EO 13526

standard handbook covers only one or two pages, the "A" page is omitted and a reduced size title page containing identical information is used preceding the text.

Types. Standard handbooks fall in one of the following two categories (aircraft handbooks and equipment handbooks):

Aircraft Handbooks. Aircraft handbooks are issued for each series of standard A aircraft to meet the needs of operating and service personnel. Every effort is made to publish these handbooks concurrently with the delivery of the aircraft to the service. Aircraft handbooks consist of the following types of publications:

a) Flight operating instructions contain all essential information required by the pilot and flight crew to operate the airplane, including all accessories and equipment, under all operating conditions. However, instructions pertaining to the basic technique of flying, or the detailed operation of armament, communicating or other operational equipment are omitted. Any unconventional characteristics which the airplane may possess are clearly described, together with the appropriate countermeasures.

b) Erection and maintenance handbooks contain all essential information required by service personnel for field maintenance purposes to service and maintain complete airplanes. They also deal with such service and maintenance as can be accomplished by operating activities on engines, accessories, instruments and associated equipment while installed in the aircraft. These handbooks contain all maintenance instructions from minor adjustments, tests, and inspections to major disassembly and repair of the airframes and controls with the exception of structural repair, which is included in handbooks on structural repair.

c) Structural repair handbooks contain all essential information required for determining the extent of any damage to the aircraft and for its repair.

d) Inspection and maintenance requirements handbooks for use by inspectors, crew chiefs, mechanics, and other concerned personnel, are issued to insure that periodic inspections performed by such individuals meet established standards of thoroughness. These handbooks, which are being issued as rapidly as possible to replace the present aircraft inspection and maintenance guides, contain brief, concise lists of aircraft, engine and associated equipment items which are to be inspected at designated periods. They also contain information pertaining to the accomplishment of minor maintenance work. The information contained in these handbooks will replace that contained in the inspection section of the aircraft erection and maintenance handbooks and the equipment operation and service instructions handbooks.

e) Basic weight check list and loading data handbooks contain detailed weight and balance data for specific models of aircraft for use in the Handbook of Weight and Balance Data, AN 01-1B-40. General information pertaining to the AF system of weight and balance control of aircraft is outlined in Technical Orders of the 01-1B series.

Equipment Handbooks. Equipment handbooks, covering specific items of airborne and ground equipment, are issued to cover overhaul procedures and, when necessary, to provide operating and service instructions for these items of equipment. Equipment handbooks include the following types of publications:

a) Operation and service instruction handbooks provide instructions for operating, storage, service, routine maintenance and trouble shooting data of items of AF equipment. Complete handbooks of this type are issued for items of ground equipment, and for the more complicated airborne accessories and systems, such as remote control turret systems, which cannot be adequately covered in the standard handbooks for aircraft.

b) Overhaul instruction handbooks contain information for the disassembly, inspection, repair, reassembly, and testing after overhaul of AF equipment other than aircraft.

Miscellaneous Technical Orders

General. Publications of this type are issued for specific purposes to disseminate information and instructions not provided for in standard handbooks. Generally speaking, these Technical Orders cover a wide range of

subjects which, in some instances, cannot be readily grouped into distinct classes. Miscellaneous Technical Orders include indexes of various kinds, lists of applicable publications for individual aircraft models, kits and sets of equipment publications, radio facility publications, parts interchangeability publications, engineering manuals, and technical orders which explain systems and procedures governing technical publications, classification of equipment, maintenance, overhaul and supply of AF equipment.

Format. Miscellaneous Technical Orders are issued with full size title pages and "A" pages, except when the material in such publications is limited to a few pages and when a reduced size title page may be advantageously used. Arrangement of data in such Technical Orders varies in accordance with the intended purpose of each publication and usually does not follow any prescribed specifications such as those established for standard handbooks.

Indexes. Indexes are issued to familiarize AF personnel with the availability and status of technical publications. The basic index, covering the entire technical publications system covered herein, is T.O. 00-1-1, Numerical Index of Technical Publications, more fully described later in this section, and referred to hereinafter as the "numerical index." Separate indexes or lists are issued to cover publications relating to specific types of equipment such as communications, armament, vehicles, marine, and motorized equipment.

Lists of Applicable Publications. Lists of applicable publications for individual aircraft series are issued and augmented by cumulative supplements to enable AF personnel to select and become familiar with technical publications pertinent to assigned aircraft. The applicable publications indicated in these lists are arranged numerically with important supplementary data denoting the type of each publication, time and place for any required compliance action, the forms on which entries are required, periodic inspection periods, and the serial numbers of aircraft affected. Lists of applicable publications are effectively employed as check lists for compliance with Technical Orders and also assist in determining publications required for limited technical publication files.

Kit Publications. Kits and sets of equipment Technical Orders, commonly known as the "00-30" series, itemize components of kits and sets of equipment which are prescribed in equipment authorization tables (Tables of Organizational Equipment and Tables of Allowances).

U.R. Digest (T.O. 00-10-1). The U.R. Digest contains data regarding corrective actions for unsatisfactory conditions reported by service activities when such actions are not mandatory but are of value to the service. The information is arranged under appropriate subjects with brief explanations of the difficulty, its cause, and the recommended corrective action.

Radio Facility Publications. Radio facility publications are issued primarily to make available to pilots, navigators, and radio operators, current information on radio aids to navigation. This type includes the AF Radio Facility Charts, T.O. 08-15-1, and AF Radio Data and Flight Information, T.O. 08-15-2.

Microfilm Drawings. T.O. 00-5-4, "Explanation of the Distribution and Numbering System for Microfilm Indexes," is a miscellaneous Technical Order. The indexes referred to therein, however, are special publications (Figure 2-8).

Parts Catalogs and Spare Parts Lists

Purpose. Parts catalogs are issued for the primary purpose of identifying parts and to act as aids in the requisitioning of parts for AF aircraft and equipment. A similar purpose is served by spare parts lists which are issued, in most instances, to cover communications equipment.

Contents. Parts catalogs usually contain a section providing a numerical parts list and another section outlining these data by group assemblies with illustrations of such assemblies. Complete nomenclature and part numbers are provided in these catalogs. In most instances the part numbers shown are those of the manufacturers. Spare parts lists are less comprehensive publications containing a detailed listing of items with assembly designations, descriptions, and manufacturer's part numbers.

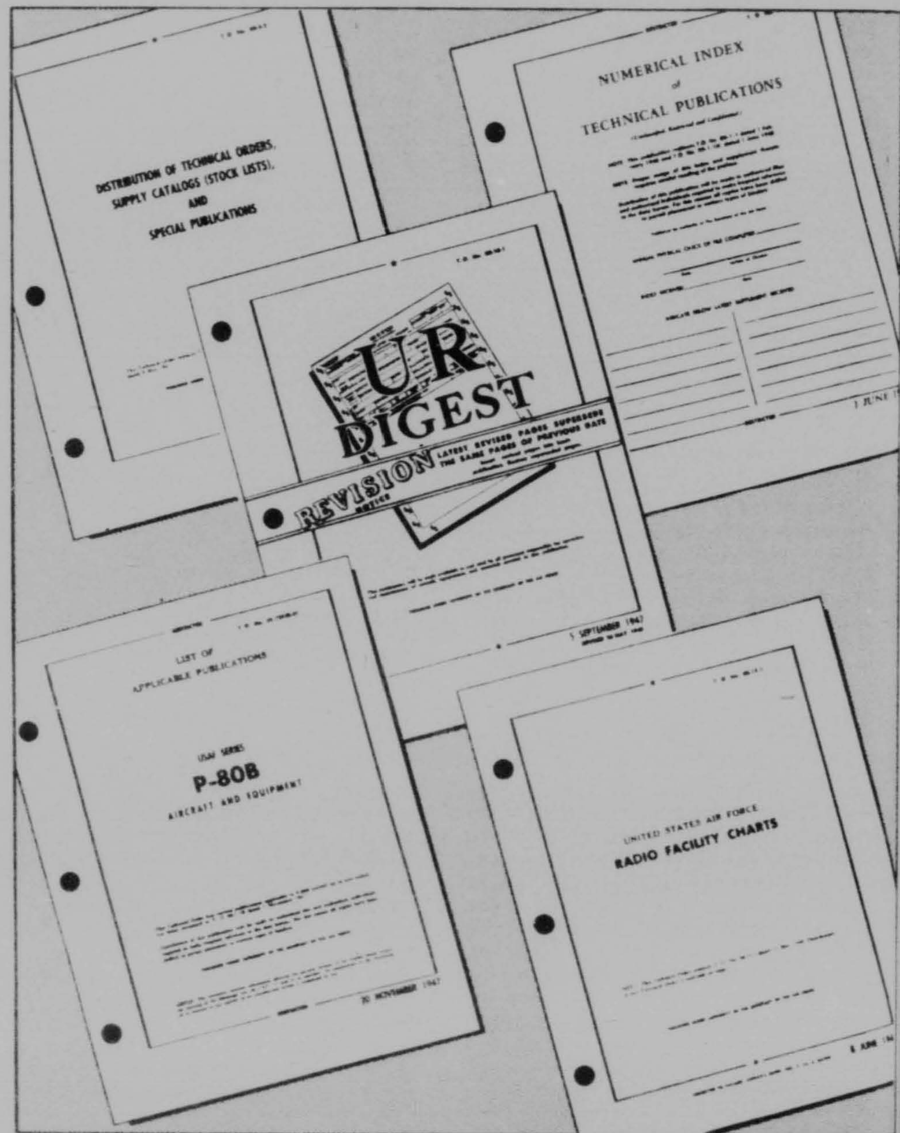

Figure 2–8. Miscellaneous Technical Orders.

Format. Parts catalogs and spare parts lists are published with title pages and "A" pages similar in design to those employed for standard handbooks, except that the words "Parts Catalog" or "Spare Part List" precede the names of the equipment covered by these publications. Data contained in these publications are arranged in tabular form.

Supply Catalogs (Stock Lists)

The purpose, contents, and use of Air Force supply catalog will be discussed in the section titled "Armament Supply."

7. SPECIAL PUBLICATIONS

General

Publications in this group are issued to implement or sometimes supplement information or procedures contained in technical orders. In most instances, a special publication is a more convenient medium for usage on the job, as it is designed in a size and form to serve best the intended purpose.

Principal Types

Air Crew Check Lists. Air crew check lists, printed on 5 inch x 8 inch cards for convenient usage, are issued primarily for transition training purposes. Separate check lists of this type are issued for pilots and other crew members. All such check lists are published under the authority of AF Regulation 62-2.

Indexes of Microfilm Drawings. Original engineering drawings of aircraft, engines and accessories are reproduced on microfilm for limited distribution to USAF activities. Indexes are published and are made available only with sets of microfilm drawings in accordance with AF Regulation 5-17. Instructions on the use of microfilms and microfilm equipment are contained in T.O. 10-1-135. An explanation of the methods used for indexing, requisitioning, and distributing microfilm drawings is contained in T.O. 0-5-4.

Printed Drawing Books. Printed drawing books are bound reproductions of engineering drawings in 22 x 34 inches and 17 x 32 inches size, covering certain types of aircraft or aircraft accessories manufactured by a specific contractor. Procurement and distribution of new printed drawing books and revisions thereto is no longer being made.

AF Maintenance Charts. Maintenance instruction charts and engine limits and lubrication charts are charts 22 x 34 inches and 20 x 30 inches respectively, for use by maintenance personnel in the maintenance of AF equipment and for instructional purposes. They are available upon requisition only. Procurement of new engine limits and lubrication charts is no longer being made.

Changes to Publications

Methods Employed. Changes to existing Technical Orders and special publications are made either by means of revisions, reissues, supplements, appendixes or addenda. Use of loose-leaf format permits efficient, economical, and speedy revision of many types of technical publications within the system. Removal of publications from active status is accomplished by rescission or replacement.

Indexing and Numbering

Indexing. General. Official listing of active Technical Orders, supply catalogs (stock lists) and special publications is accomplished in the numerical index, which is issued at extended intervals and augmented every two weeks by a cumulative supplement. The numerical index and supplements thereto provide a ready reference to existing publications and are used in maintaining publication files in current status.

Note: To determine what publications are active and available, it is necessary to use only the current cumulative supplement in conjunction with the basic numerical index.

Basic Numerical Index (T.O. 00-1-1). The basic numerical index lists all active publications within the system which have been distributed to AF activities prior to the publication date shown on the title page of the index. When reissued, the basic numerical index is revised to delete listings of rescinded or replaced publications and to incorporate data concerning publications distributed since the previous issue of the basic index.

Supplements. Supplements of the numerical index contain lists of newly issued, revised, reissued, superseded, replaced, and rescinded

THIS PAGE IS DECLASSIFIED IAW EO 13526

publications. All such supplements are cumulative and are numbered T.O. 00-1-1A, -1B, etc. Cumulative supplements also list all publications, including revisions and reissues, scheduled for future distribution.

Numbering

General. Numbers are assigned to Technical Orders, supply catalogs (stock lists), and some categories of special publications for purposes of ready identification, indexing, referencing, and filing. The assigned numbers follow the appropriate identifying prefix, such as "T.O. No." for technical orders, "S" for supply catalogs (stock lists), "C" for AF maintenance charts, and "MF" for microfilm drawing indexes.

Technical Orders. Technical Orders, including AN publications, are assigned numbers of two or more parts (usually three parts), separated by dashes. The first part of the number identifies a particular section of publications in the numerical index, i.e., "01" indicates Technical Orders in Section 01, "Aircraft Publications." The second part of the number is related to the series and subseries to which a Technical Order is assigned for proper grouping of equipment by type, system, model, or manufacturer. Alphabetical letters are added to the second part of the number to segregate further the equipment covered. The final part of the number is employed to list numerically, Technical Orders within a given series or subseries, i.e., -1, -2, -3, etc. A suffix letter is added to this part of the number when supplementary information is issued as a separate publication.

Aircraft Inspection and Maintenance Publications. Guides. Existing aircraft inspection and maintenance guides are basically numbered "00-20A" to indicate the relationship of these publications to T.O. 00-20A, "USAF Aircraft and Related Airborne Equipment Inspection and Maintenance System." This basic number is followed by the aircraft series number applicable to each guide. For example, the inspection guide for B-29 aircraft is numbered "00-20A-B-29." A prefix is not employed for these publications.

Inspection Handbooks. In the future, inspection and maintenance requirements will be published in the form of standard handbooks in the applicable aircraft Technical Order series. The number to be assigned will normally be the "-6"; for example, the inspection and maintenance requirements handbook for the B-36 aircraft is numbered "T.O. 01-5FUA-6."

AF Maintenance Charts. Maintenance charts are numbered in a manner similar to Technical Orders, except that the prefix "C" is used instead of "T.O. No."

Indexes of Microfilm Drawings. Microfilm drawing indexes are numbered in the same manner as Technical Orders, except that the prefix "MF" is used to distinguish this type of publication from standard Technical Orders.

Security Classification

Technical Orders, supply catalogs (stock lists), and special publications are published as unclassified, restricted, or confidential documents. The classified publications (restricted and confidential) are appropriately marked on their title pages and, when required, on all subsequent pages of such publications. Publications listed in the numerical index, and supplements thereto, are unclassified except when the word "RESTRICTED" or "CONFIDENTIAL" appears in bold face type immediately following the title of the publication.

Classified publications in file which have been downgraded are not reprinted and distributed merely to reflect a change in classification. Revisions or reissues to such publications, however, will reflect the current classifications. Confidential publications must be maintained in separate file and safeguarded in accordance with the provisions of AR 380-5.

Rescinded and replaced (or superseded) publications, which are no longer required, will be removed from the file and disposed of as follows:

If unclassified, dispose of in accordance with instructions of the local salvage officer.

If classified, destroy in accordance with the provisions of Army Regulation 380-5.

Note: Additional information on technical publications can be found in T.O. 00-5-1.

The Air Force technical publications are listed numerically in T.O. 00-1-1.

The alphabetical Index of Technical Publications is T.O. 00-1-2.

CHAPTER 3—ADMINISTRATIVE DUTIES OF ARMAMENT OFFICER

SECTION I—ARMAMENT OFFICER'S DUTIES

1. GENERAL

The Air Force armament officer's primary responsibility with respect to armament is that tactical airplanes shall at all times be fully ready to perform their missions under full military load. In order to fulfill his primary responsibility, the armament officer must:

Educate personnel in their command in the importance of safe operation, preventive maintenance, and training to perform their prescribed preventive maintenance duties regularly and properly.

Requisition all correct official Department of the Army and Department of the Air Force publications dealing with maintenance and operation of equipment under their control and make these publications available to personnel responsible for carrying out these instructions.

Requisition all authorized tools, equipment, supplies, and parts required to accomplish preventive maintenance services.

Schedule periodic preventive maintenance services for equipment under their control as specified in official publications concerning the equipment, allowing adequate time for the completion of these services by responsible personnel.

Periodically inspect materiel, including the tools, supplies, and parts needed for maintenance operations. (This is to insure that operation of equipment and performance of preventive maintenance services thereon, including handling, packing, transport, and storage, conform with current regulations and standard practices.)

Prevent the abuse of materiel under their control. (Evidence of abuse must be investigated and appropriate action taken thereon.)

Prevention of abuse of materiel is one of the most important responsibilities of the armament officer. Some of the more common abuses he must guard against are:

Improper, careless, or negligent use or operation of materiel.

Lack of lubrication, overlubrication, or use of unauthorized lubricants.

Lack of inspections.

Deferred maintenance, including lack of proper servicing and adjustments.

The attempting of repairs by unqualified personnel or by use of improper or inadequate tools, parts, and equipment.

Rather than explain each responsibility separately, this section and those following will explain in general the information that must be known before an Air Force armament officer may fulfill his responsibilities.

2. DUTIES OF AN ARMAMENT OFFICER

The armament officer has many duties, and among the more important he does the following:

a) Supervises loading of bombs into bomb-racks and ammunition into ammunition boxes of combat aircraft. (It is now the normal function of the armament section to transport bombs or other ammunition from the ammunition dump to planes. Transportation, fusing, and delivery of bombs and belted ammunition from the dump to airplane is also exclusively an armament function. At the airplane, the armament crew assumes charge, and arms the planes with the bombs and ammunition that have been brought to the loading point, that is, the plane.)

b) Acts as a special staff officer to the commander, keeping him and the operations officer advised as to:

Serviceability of armament.

Performance of armament under varying climatic conditions.

Status and availability of armament equipment and supplies.

Logistical data concerning armament equipment.

Probable errors in bombardment and gunnery.

c) Maintains proper and accurate records of expenditure of ammunition, flares, bombs, and other ordnance supplies; of status of equipment, and of bombing and gunnery scores. (In some units, these records may be kept for the armament officer by the ordnance section, but in either case they are closely coordinated with those of the operations officer. Such records are periodically forwarded through channels to higher headquarters; their importance lies in the fact that the maintenance of an adequate ammunition reserve will depend upon the accuracy with which they are kept and the promptness with which they are forwarded.)

d) Keeps a status board or chart showing at all times the dates upon which inspections of aircraft armament equipment have been completed.

e) Sees that all unit armament supplies are properly and promptly procured and distributed.

f) Procures and keeps up to date files of technical publications bearing upon maintenance, operations, and storage of armament and chemical equipment.

g) Maintains all necessary records, reports, files, and correspondence bearing upon work of armament and chemical sections.

h) Supervises training of air crews in use, and of air and ground crews in maintenance, of all armament equipment.

i) Procures, equips, and supervises ranges for gunnery and bombardment practice, and rigging of tow targets.

j) Schedules use of gunner, bombardment, and small arms ranges.

3. DUTIES OF A UNIT GAS OFFICER

The unit gas officer must:

a) Train the required number of chemical NCO's for the unit.

b) Train all unit personnel in all matters pertaining to defense against chemical attack, including:

Gas mask drill.

Detection and identification of chemical agents.

Detection and posting of gassed areas.

First aid for chemical casualties.

All methods of decontamination, including decontamination of planes and other equipment.

c) Give necessary specialized instruction to personnel detailed as gas sentries.

d) Prepare standard operating procedure for defense against chemical attack.

e) See that an adequate system of gas alarms and gas-proof shelters is maintained.

f) Maintain a constant check on status of supplies of chemical protective equipment.

g) See that chemical warfare equipment is properly used.

h) Supervise administration of the chemical section, including preparation and forwarding of all necessary reports and correspondence.

i) Maintain necessary records and files.

4. DUTIES OF AN ORDNANCE OFFICER

The duties of the ordnance officer include:

a) Storage and supply of completely assembled bombs, pyrotechnics, and belted ammunition to the squadron. (Within this responsibility rests the proper loading of bomb components for required complete rounds, and assembly and fusing of rounds at the bomb fusing point; within it rests also the delivery of complete assembled rounds to aircraft personnel [armament] at the bomb service point.)

b) Daily compilation of the status of ammunition report. (As has been pointed out, the armament officer, within whose duties lies the supervision of bombardment practice, has his own reports to coordinate with those of the operations office. All data on ammunition expenditure must be accurate and must be rendered promptly if an adequate supply for planned operations is to be available.)

c) Estimate of ammunition requirements for forthcoming operations. (This duty requires the closest coordination with the operations officer, since operations and intelligence alone have a preview of scheduled events.)

d) Inspection, repair, and maintenance of all ordnance materiel within his command. (Ordnance materiel is that materiel that is procured and issued by the Ordnance Department.)

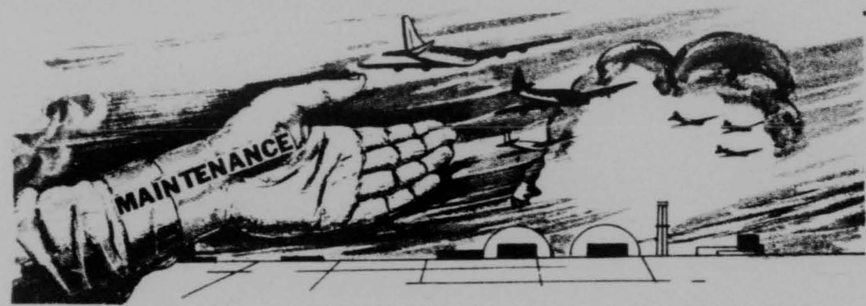
e) Maintenance of records, correspondence, forms, and files relating to ordnance matters and to training of ordnance personnel.

f) Cooperation and coordination with the armament and chemical warfare officers.

g) Serving as technical adviser to the commander on ordnance matters, including supply, storage, use, operation, and performance of ordnance materiel.

h) Supervising disposal of unexploded bombs in the areas.

SECTION II—MAINTENANCE



1. GENERAL

It is the purpose of the following to introduce to the student the fundamentals of maintenance and to acquaint him with the Air Force maintenance system in order that he may better understand his maintenance responsibilities.

Maintenance is the normal upkeep and preservation of equipment which may be necessary from time to time because of usage, wear and tear, or deterioration by the elements.

Every member of the military forces has a definite maintenance responsibility. Maintenance responsibilities vary, from preventive maintenance operations employing highly specialized repair and reconditioning techniques, to the supervision and inspection necessary to insure that equipment is ready for use. Personnel operating equipment, technical maintenance experts, and commanders of all echelons must conscientiously strive to prevent the deterioration of and to insure the efficiency of all military equipment.

Efficient maintenance dictates that the various maintenance operations which must be performed on each item be allocated to certain personnel in pre-established places.

Where and by whom any given operation is performed is determined by the facilities, nature of repairs, time available, skill of personnel, availability of tools, parts, and the need for mobility.

The system requires that all personnel receive sufficient technical training to perform their prescribed maintenance functions and that all organizations be provided with sufficient personnel, equipment, tools, test equipment, supplies, and parts to accomplish their maintenance mission.

To define responsibility and have a standardized system, the Air Force has classified maintenance into echelons that conform to the organization and mission of its units.

2. USAF SYSTEM OF ORGANIZATIONAL MAINTENANCE

Organizational maintenance will normally consist of preventive maintenance operations performed by the user, wearer, operator, or operating crews of the equipment, or by specially trained personnel of the using organization. This includes proper care, use, cleaning, operation, preservation, servicing, routine and periodic inspections, minor repair not requiring disassembly of subassemblies, and accomplishment of instructions as directed in Technical Orders and other applicable directives.

3. USAF SYSTEM OF FIELD MAINTENANCE

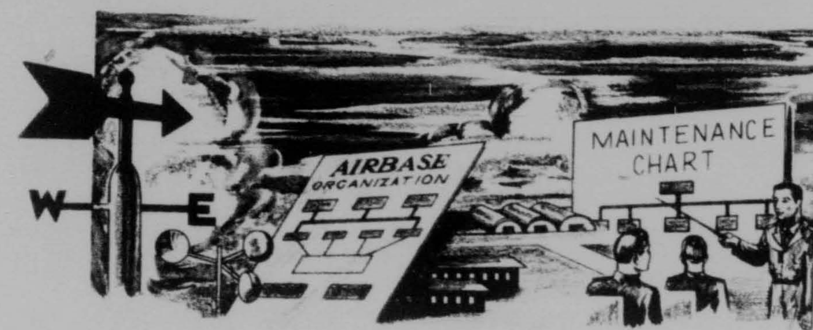
Field maintenance consists, primarily, of corrective maintenance that is beyond the scope of the using organization and is normally performed by personnel of the air base.

This includes repairs requiring fixed shops or ground mobile equipment, replacement of major unit assemblies, fabrication of parts, accomplishment of instructions as directed in publications, and such assistance to lower echelons as is necessary.

4. USAF SYSTEM OF DEPOT MAINTENANCE

Depot maintenance includes all operations necessary to restore worn or damaged equipment to a serviceable condition and the periodic overhaul of assemblies, accessories, and auxiliary items as prescribed in directives; replacement and repair of auxiliary equipment; fabrication of such parts as may be required in emergency; and technical advice and assistance on maintenance matters to USAF activities. Depot maintenance may be limited or specialized as directed by higher headquarters. It is normally performed by the air depot.

SECTION III—FACTORS AFFECTING MAINTENANCE



1. GENERAL

In some organizations for maintenance there have been no T O&E's published because of variable factors affecting this type of organization. The most important of these factors include: weather and climate, mission of the base, physical plant of the base, experience of personnel, and tools and equipment.

2. WEATHER AND CLIMATE

There are several weather and climatic conditions which affect the efficiency of the operation of equipment as well as the efficiency of maintenance operations. Among these are arctic, desert and tropical conditions.

In arctic operations, the efficiency of the equipment is reduced by low temperatures causing congealing of lubricants and by reduced capacity of storage batteries. In addition, the efficiency of maintenance personnel is reduced. It is necessary to provide elaborate shelter, clothing, and heating equipment, for sustained work is impossible under exposed arctic conditions.

In tropical climates, the main problems are accelerated corrosion and deterioration of equipment and reduction of efficiency of personnel due to the high heat and humidity.

In desert conditions, the main problems are the rapid failure of moving parts due to the abrasive action of sand and dust and the reduced efficiency of personnel in extreme heat.

3. MISSION OF THE BASE

Air Force bases are organized so that they may carry out most efficiently their particular functions; there will necessarily be organizational differences to meet the specific re-

THIS PAGE IS DECLASSIFIED IAW EO 13526

quirements of their mission. The general classification of wing bases are combat or air transport, training, and depot.

4. PHYSICAL PLANT OF THE BASE

Physical facilities of the base provide a plant in which assigned work is accomplished. The layout of these physical facilities has a direct and important bearing on the efficiency with which work is accomplished. A poorly laid out plant is a problem because correction is always difficult and sometimes almost impossible. New construction, extensive relocation, or modification of existing buildings is usually out of the question. In general, it is necessary to use existing facilities as they stand, assigning functions, consolidating activities, and localizing to improve maintenance efficiency.

5. EXPERIENCE OF PERSONNEL

The fourth factor affecting maintenance is the experiênce of personnel. Development of adequate personnel begins with the selection of personnel after they have successfully passed the evaluation and proficiency tests. They should be selected for specific duties and assignments, and every effort made to utilize previous experience. Additional training will be made available by means of technical service schools and by on-the-job training. Supervisory training involves other and more complex factors, and is normally best given by classroom methods, personal instructions, and by example. Good operation provides for continuous evaluation and training.

6. TOOLS AND EQUIPMENT

Another element consists of adequate tools and equipment, and is a mandatory requirement if quality work is to be accomplished. Tools, tool equipment, and test equipment are allocated to the various types of organizations in accordance with authorized items. Tools and tool equipment, including test equipment, are generally considered as being divided into two groups, common and special. In most cases, these items are grouped in standardized sets and authorized for issue in supply catalogs or other official supply publications. Special tools for using organizations are closely allied to the major item to which they apply and are listed in T O&E or supply catalogues in conjunction with spare parts and accessories applicable to the major item.

The relationship of supply and maintenance cannot be overemphasized. The most qualified maintenance personnel in the Air Force may be available but unless the spare parts or maintenance supplies are available the specialized mechanic is useless. The converse is likewise true. Tons of spare parts or equipment in need of repair may sit idle for the lack of maintenance personnel. More than one-half of the items supplied by the Air Force and Army are those required for the maintenance of our equipment.

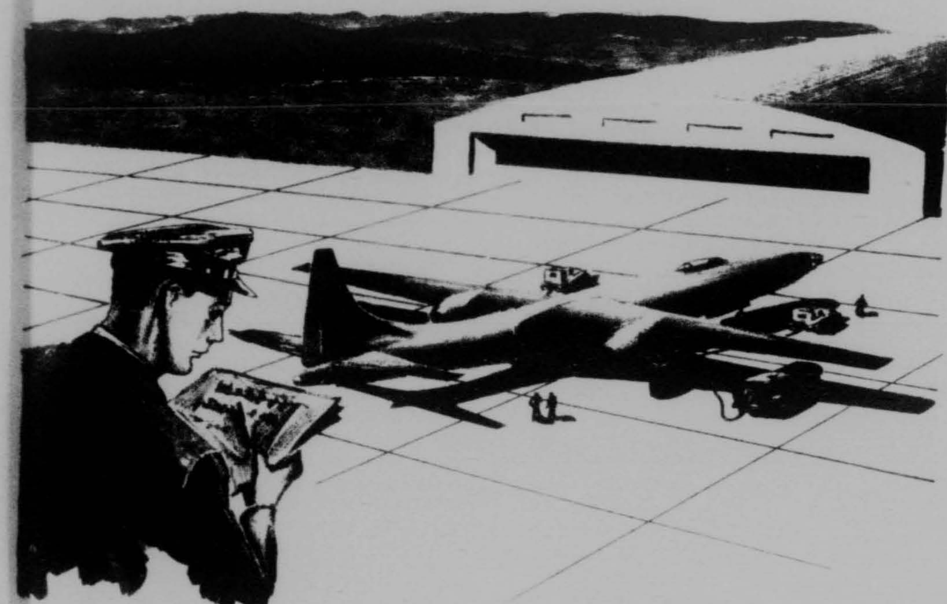
The major objective in building a maintenance organization is to provide a basis by which management (commanding officer) and supervision (armament officer) can effectively utilize the personnel, equipment, and facilities under their control to accomplish the:

Prompt return of unserviceable material to a serviceable condition.

Preventive maintenance inspections as required by publications.

Emphasis should be placed on good housekeeping, safety, security, fire prevention, records and reports, and training.

SECTION IV—AIRCRAFT MAINTENANCE



1. GENERAL

Since most of the air armament officers will be assigned to tactical organizations and be responsible for organization maintenance on aircraft, we will discuss the inspection and maintenance system as devised by the Air Force. This system is known as the "USAF Aircraft and Related Airborne Equipment Inspection and Maintenance System" and is explained in Technical Order 00-20A. This system provides the basic means of maintaining the highest possible percentage of aircraft in readiness for flight. This system operates by the use of maintenance record forms, Technical Orders (directives), inspection and maintenance guides (when applicable), and periodic inspections.

2. PREVENTIVE MAINTENANCE

Preventive maintenance is the regular periodic servicing and systematic detection and correction of failure in equipment by the operators and maintenance personnel. This includes a system of checks, inspections, and services performed on materiel to insure that it is kept in top operating condition, and to detect and correct minor troubles before they develop into major defects.

Preventive maintenance services, properly applied, keep equipment in the best possible operating condition; decrease the need for service maintenance, with a resulting saving of time, personnel, and expense; obtain the longest possible life of equipment and parts, thus reducing requirements for replacement parts; and assure the proper handling, packing, transport, and storage of equipment.

3. DUTIES AND RESPONSIBILITIES

Individuals. Individual users, wearers, or operators of equipment are responsible for the performance of all preventive maintenance

THIS PAGE IS DECLASSIFIED IAW EO 13526

services prescribed in the official Department of the Army and Department of the Air Force publications dealing with operation and maintenance of their equipment, and for the preparation of records and reports as specified in these publications.

Unit Mechanics of Using Organization. Specially trained maintenance personnel are responsible for the performance of all unit preventive maintenance services and for the preparation of records and reports on these services, as specified in the official publications concerning the operation and maintenance of their equipment.

Armament Officer. Establishes major purposes and objectives for the armament section, establishes departments for those groups which have related functions and provides supervision and inspection over all armament operations.

4. MAINTENANCE RECORD FORMS

These forms are used for the purpose of recording flying time, status of maintenance, operational fitness of the aircraft, and maintenance performed or required. They also include a record of all Technical Order compliances that are accomplished and required. Records transfers, depot inspection and repair or overhaul, damage to or replacement of major components, and total operating time.

5. TECHNICAL ORDERS

These are directives published by order of the Secretary of the Air Force for the purpose of issuing specific directives and technical information covering the operation, maintenance, storage, inspection, etc., of Air Force equipment and materials. Technical Orders are also published when the aircraft and related equipment requires modification. A modification is a specific authorized change in the design of assembly of an item of materiel to meet revised specifications or to correct defects. Modification of materiel is authorized only when it:

Is essential to the safety of personnel, or,

Prevents breakage or destruction of materiel, or,

Substantially improves effectiveness.

6. INSPECTION AND MAINTENANCE GUIDES

These guides contain pertinent inspection and maintenance data plus supplementary information for inspectors, crew chiefs, mechanics, and other interested personnel. The information in the Guide summarizes the more detailed instructions incorporated in the Technical Order. These guides are gradually being replaced by a Technical Order titled "Aircraft Inspection and Maintenance Requirements Technical Orders."

7. PERIODIC INSPECTIONS

The periodic inspections required for all USAF aircraft are: preflight, daily, 25-hour (minor), 50-hour (major), 100-hour (major), 200-hour and subsequent (major). A new system of inspection periods has been established and will gradually be adopted as the new Aircraft Inspection and Maintenance Requirements Technical Orders are issued. The above periodic inspections will be disregarded and the inspection periods in the new Technical Orders will be followed.

To insure that the quality of inspection and maintenance being performed is adequate, a continuous observation and evaluation of the periodic inspections must be conducted.

8. TYPES OF AIRCRAFT MAINTENANCE

To enable unit commanders to meet their objectives efficiently by adopting the method of accomplishing inspections most applicable to their local facilities and assigned personnel, one of the following listed methods will be utilized:

Crew chief method.
Production line method.
Consolidated inspection method.
Specialized inspection method.

9. CREW CHIEF METHOD

This method is by far the oldest and, in many respects, the most desirable system of maintenance since it allocates the responsibility for getting the job done to one individual. This method is the system whereby all periodic inspections of aircraft are made by

the crew chief and his assistants. This method is well adapted to situations when there are relatively few aircraft of various types and sizes. This system emphasizes individual merit and personal accomplishment; however, it has obvious disadvantages. Much training is required of a crew chief. Airplanes are becoming so complex that it is almost impossible for one man to master the complicated mechanism of all the equipment.

10. PRODUCTION LINE METHOD

This is an industrial system whereby periodic inspections of aircraft are accomplished by three or more inspection crews, each of which is assigned a specific set of tasks. The inspection crews are permanently assigned at a like number of fixed stations, especially equipped with tools, supplies, and equipment appropriate to the phase of the inspection assigned to the station. The aircraft are towed or pushed at established intervals to these fixed stations with their assigned inspection crews.

The advantages of a PLM is that inexperienced personnel may be utilized, since only one job has to be taught each individual on a line. It standardizes maintenance; by grouping tools together it provides maximum usage. It provides excellent on-the-job training.

The disadvantages are that it requires extensive planning and does not provide the spirit of responsibility and accomplishment attained by the crew chief method. PLM requires numerous maintenance hangars and is not very well adapted to maintenance in the field. It is adapted to maintenance of one type aircraft per production line only. It requires a maximum of good supervision. Due to the employment of work shifts there is much overlapping of responsibility.

11. CONSOLIDATED INSPECTION METHOD

This is the system whereby complete periodic inspections are made at appropriately-equipped docks or other fixed installations by a permanently-assigned inspection crew of aircraft mechanics, specialists, and trainees. Under the direction of a dock or station chief, these inspection crews accomplish all work involved by the inspections while the aircraft remains at the station. This system is especially adapted to very large airplanes where the installed equipment is complex and where there are no hangar facilities for performing maintenance under shelter.

12. SPECIALIZED INSPECTION METHOD

This is the system whereby major periodic inspections of aircraft are made at fixed station locations equipped with docks, work stands, testing apparatus, etc. Three or more roving inspection crews perform their phase of the completed inspection. With this system, the airplane, after being decowled and cleaned, is moved to the fixed station location where it remains until the inspection is completed. The specially-trained inspection crews move at intervals from one station to another and perform their respective tasks on a time schedule basis.

This system has the advantage of requiring a minimum of movements of aircraft since the work can be performed in dispersal areas. This system requires a large amount of transportation since each specialized crew is required to move from airplane to airplane. It appears that this method is the best suited for future combat units.

The preceding methods will be used for basic on-the-job training. Field maintenance can be performed by modification of the above method but is usually performed by specialized crews. However, in some cases, where the volume of work can sustain the production line, it is feasible to set up a production line for repairs.

Depot maintenance usually incorporates production line maintenance in the periodic overhauling of assemblies and accessories; but where the job order is small, it is often impractical to set up a production line.

SECTION V—UNSATISFACTORY REPORTS AND INSPECTIONS

1. REPORTS

All operations, maintenance, inspections, modifications, etc., are done according to the directives published by the Departments of the Army and Air Force. No changes or modifications may be done on equipment of the Air Force or Army without authority.

When an item appears to be unsatisfactory in design or material USAF Form 54 (Unsatisfactory Report) is submitted by the using or service organization. AFR 15-54 and T.O. 00-35D-54 will explain the purpose, scope, preparation, submission, etc., on the unsatisfactory report. Reports received from the field are analyzed and if a modification is justified, the head of the technical service concerned coordinates the publication and distribution of modification work order with the production of necessary parts, tools, or other materials required for the modification. Similarly, a technical order will be issued for Air Force materiel.

Note: Alterations or modifications of equipment may not be made except in compliance with an authorized modification work order or USAF Technical Order.

USAF Form 54 is the means whereby the operating units of the Air Force report to the Air Materiel Command failures of equipment, discrepancies in systems and procedures, or errors in forms and publications. These reports are initiated by any individual assigned or attached to the Air Force upon the first and all subsequent observations of an unsatisfactory condition falling within any of the following categories:

Unsatisfactory design.

Failure or malfunctioning of any item of government materiel or equipment used by the Air Force.

Defects due to faulty materiel, workmanship, or quality inspection.

Unsatisfactory maintenance or supply methods, systems, or forms.

Discrepancies in Technical Orders and malfunctions of the Technical Order distribution system.

Equipment authorized in tables of allowance which is unsuitable, inadequate, or excessive for the mission for which required.

Technical Orders of the 00-30 series prescribing equipment which is unsuitable, inadequate, or excessive for the functions for which required.

Deficiencies in Administrative methods.

Technical Orders of the 00-10 and 00-65 series contain a listing of all unsatisfactory reports that have been submitted along with corrective action to be taken.

To insure that the more urgent modifications are applied first, the Air Force has established a system of classification and markings on their Technical Orders to enable field and maintenance installations to schedule their modification work according to the urgency of each project.

The technical services have also established a system for the same purpose. The priority designation will appear on the printed modification work order and Technical Orders.

Special or emergency cases of malfunctioning or failure likely to result in grounding or holding aircraft out of commission, particularly where like equipment may be affected elsewhere, must be reported immediately by radio, wire, or telephone direct to the Commanding General, Air Materiel Command, Wright Field, Dayton, Ohio. This will include malfunctioning or failure disclosed by accidents or forced landings. In those cases where an accident occurred as the result of a failure, an appropriate comment to this effect must be included in the Unsatisfactory Report.

2. INSPECTIONS

Inspections of Army and Air Force materiel issued to organizations are conducted for the purpose of determining the condition of the materiel and detecting the cases of neglect and malpractice which reduce the life and operating efficiency of the item.

3. FORMAL INSPECTIONS

There are two kinds of formal inspections —"command and technical."

Command. Command inspections are conducted by all commanders to determine the condition and proper use of equipment and supplies, and to insure that the subordinate commanders are complying with established procedures and regulation.

Technical. Technical inspections are performed by technicaly qualified personnel under direct supervision of qualified officers, and consists of:

Complete examination and tests of materiel to determine its serviceability, completeness, and readiness for intended use.

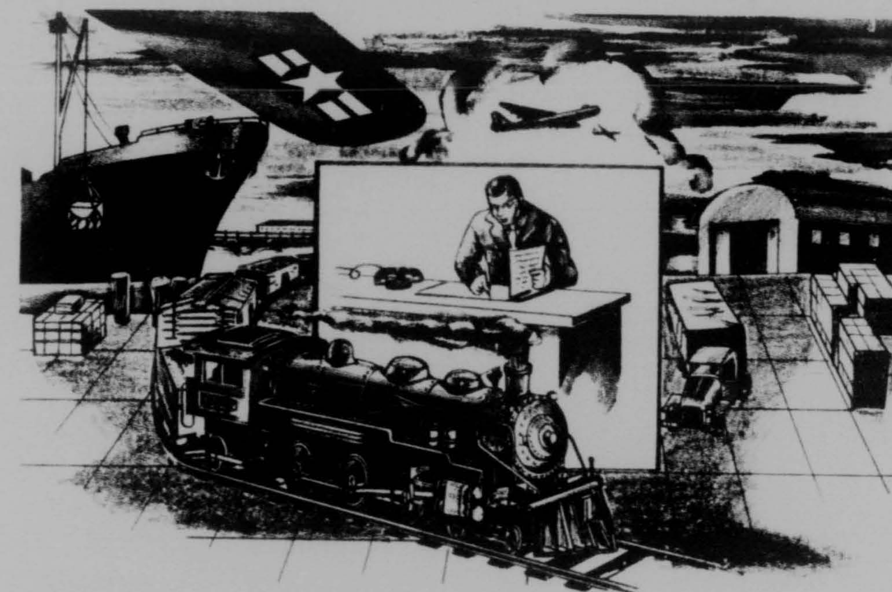
Limited examinations to determine general serviceability, and to classify materiel as to general condition.

4. INFORMAL INSPECTIONS

In addition to formal inspections, frequent informal inspections of materiel will be made by the operators, users, or wearers as part of scheduled preventive maintenance services.

THIS PAGE IS DECLASSIFIED IAW EO 13526

CHAPTER 4—ARMAMENT SUPPLY



SECTION I—INTRODUCTION

1. ARMAMENT SUPPLY—GENERAL

This section is devoted to basic supply subjects. It is not to be assumed, however, that it covers the entire supply field, or that it represents all the armament officer should know about supply. Basic supply is the minimum essential review necessary to prepare the student for additional supply instruction.–The armament officer will be faced with additional supply matters throughout his career in "Supply Planning, Logistic Estimate of the Situation, Administrative Instructions," and others.

Prior to the armed service unification in 1947, the Army Air Forces operated as an element of the War Department. Broad planning and coordination of supply was accomplished by the War Department; the Air Force was concerned primarily with Air Corps technical supplies. Today the situation is changed. Since the Air Force is an independent agency, it is responsible for planning and coordination of its own supply. In considering supplies used by the Air Force, one must take into consideration both Air Force technical supplies and supplies procured by the several other departments of our national defense organization, i.e., supplies used by the Air Force, such as clothing, tentage, general purpose vehicles, floating equipment, weapons, ammunition, etc.

The two basic classifications covering all such supplies used by the Air Force are: (1) common supplies, and (2) Air Force technical supplies.

Common supplies are defined as those supplies procured by the Department of the Army, Navy, or Air Force, but used by two or more of the armed services. They include food, individual clothing, tentage, etc. Air Force technical supplies are supplies whose procurement authority has been delegated to the Department of the Air Force, such as aircraft, aircraft assemblies, engines, aircraft maintenance parts, etc., and used exclusively by the Air Force.

SECTION II—AIR FORCE TECHNICAL SUPPLY

1. AIR FORCE TECHNICAL SUPPLY SYSTEM

The supply system used by the Air Force is one of the important factors in successful air operations.

The purpose of the following is to present the background of the Air Force technical supply system, and give the student a working knowledge of the Air Force supply classification and stock numbering system. By a study of the evolution of the technical supply system, it is believed that the system can more readily be understood.

During the first World War, Army aeronautics operated as the Aviation Section of the Signal Corps. Seven depots were established to furnish supplies for the airfield, airplanes, and air and ground crews in the areas assigned to them. Four were in the zone of the interior and three were outside the continental limits of the United States.

After the Armistice of 1918, the primary mission of these depots was the storage of vast quantities of material, much of which was worn out or obsolete. This material included equipment from Europe that was of little use to Army aeronautics. This all had to be identified, inventoried, and stored. At the same time, a change of personnel took place at the depots as many officers and enlisted men left the service and were largely replaced by inexperienced civilian employees.

In May, 1918, Army aeronautics was removed from the Signal Corps and came under the control of two new offices—the Bureau of Military Aeronautics and the Bureau of Aircraft Production. The depots operated under the Bureau of Military Aeronautics until June 1920, when they came under the newly created Air Service. In July, 1921, the Supply Division of the Air Service established a new section. This section was known as the Property Maintenance and Cost Compilation Section. This section was renamed the Field Service Section.

This remained until Congress created the Army Air Corps in July, 1926, to replace the Air Service.

After the Materiel Division of the Army Air Corps was established in October, 1926, the Field Service Section became one of its units.

During World War I, the prescribed methods and procedures for the accounting of Air Corps supplies were inadequate, so the various depot supply officers added their own methods. No two depots operated alike.

Thus, after the first World War the depots became overcrowded with surplus and obsolete items of equipment. The men who staffed the warehouses did not always know what property or how much was on hand. For several reasons, records of receipt and issue were inadequate; inventory was not up-to-date; too few persons knew how to properly identify and classify items of equipment. Items were identified, stored, and issued by nomenclature alone; and since nomenclature was not standardized, trouble was common.

2. USAF PROPERTY CLASSES

The first important step in the development of the Air Force technical supply system was the establishment of a system of property classification. The system adopted by the Air Service, later used by the Air Corps, and still used without extensive modification by the U. S. Air Force, had the virtue of combining a reasonable amount of simplicity with great flexibility. This was adopted and placed in operation in the depots in 1921. This system divided Air Corps supplies and equipment into twenty-nine major classes for convenience in

DEPARTMENT OF THE AIR FORCE
HEADQUARTERS, UNITED STATES AIR FORCE
WASHINGTON

TECHNICAL ORDER
NO. 00-35A-1

23 August 1948

CLASSIFICATION OF UNITED STATES AIR FORCES EQUIPMENT AND SUPPLIES

This technical order replaces T. O. Nos. 00-35A-1, dated 18 June 1947 and 00-35A-1A, dated 18 November 1947.

SECTION I

PURPOSE

1. This technical order is published for the purpose of establishing basic principles and rules for USAF property classification. USAF property listed in current USAF Supply Catalogs at variance with the provisions of this technical order will be reclassified and transferred only as directed by Hq, AMC, on an orderly program basis, and in accordance with the provisions of Sections IV and V hereof.

SECTION II

PRINCIPLES OF CLASSIFICATION

1. BASIC PRINCIPLES.

Property classification is a systematic grouping of related items by classes.

a. A property class is established to facilitate supply of functionally related items when such items are of sufficient group importance to warrant segregation from other property.

b. A property class is often divided into subclasses to facilitate the supply of closely related items.

c. An item is assigned to a property subclass after complete identification and determination as to whether it is a special or general purpose item.

d. An item will be assigned to one property subclass.

e. A special purpose item will be reclassified in the appropriate general purpose subclass when general purpose applications are determined.

Figure 4—1. Property Classification of USAF Materiel.

procurement, storage, and issue. These classes were designated by numbers running from 01 to 29. To date there have been no changes in these numbers, designating the classes, although class 30, 31, and 32 have been added. Supplies in storage or in an issue warehouse are physically segregated in each of these classes. In other words, requisition, storage, and issue of Air Force technical supply is in accordance with these thirty-two main classes.

These classes were broken down into subclasses by adding a letter of the alphabet, i.e., 01-A, 01-B, etc. The subclasses were segregated in some cases according to manufacturer and according to item grouping in others. Examples of these classes of USAF equipment and supplies are:

01—Aircraft and Maintenance Parts.

02—Aircraft Engines and Maintenance Parts.

03—Aircraft and Engine Accessories and Maintenance Parts.

05—Aircraft Instruments.

06—Fuels, Lubricants and Gases.

11—Aircraft Armament.

16—Communications Equipment.

21—Cordage, Leather and Fabrics.

The complete property classification of Air Force equipment and supplies can be found in T.O. 00-35A-1, titled "Classification of United States Air Forces Equipment and Supplies." (See Figure 4-1.)

THIS PAGE IS DECLASSIFIED IAW EO 13526

Likewise, each of the thousands of Technical Orders that tell how to operate and maintain equipment and how to repair and modify weaknesses and defects in equipment are numbered according to the class of the item. For example: Technical Orders on aircraft will start with the number 01; for engines the number will be 02; the number 11 will be on Technical Orders that give information on armament.

3. THE AIR FORCE STOCK NUMBERING SYSTEM

While the thirty-two main property classes and their subdivisions served very well for segregating items in storage, they did not provide identification for listing or cataloging the thousands of items of Air Corps supply. In 1929, tabulating machines for recording stock balances and consumption data were installed in all the depots. These machines had no letters and could punch only numbers on the tabulating cards. Therefore, a new system of class code numbers running from 01 to 99 was adopted, grouping items according to use or nomenclature. There is no connection between the class numbers 01 and 99 and the class symbols 01A, 01B, etc. However, it was originally intended that the code numbers would be a numerical equivalent to the class symbols of numbers and letters, and that fact makes the classification system especially confusing to the individual who is not familiar with it.

The class code provides a positive numerical identification of Air Force equipment, facilitates accurate requisitioning, procurement, storage, issue, inventory and disposition of property.

These basic class codes running from 01 to 99 may indicate:

An entire class of supply (class code 01 designating the entire class of aircraft and maintenance parts).

A subclass (class code 40 designating subclass 03-A, propellers and related parts).

A special grouping of material (class code 91 designating shop and warehouse machinery, power tools, and equipment).

Although the code number was first adopted due to the limitations of the tabulating machines, it has been especially important since 1935, when it came to be used as the first element of the stock number of every item of Air Corps property.

For each separate piece of Air Force equipment there will be a stock number assigned. A separate stock number will be assigned for each item in order that the USAF activities can accomplish positive numerical identification of USAF equipment and supplies.

In all cases a stock number consists of two elements. The first is a four-digit classification code number that is referred to as either the class code number or the classification code number. The second element is called the serial number. It will consist of a number of not more than fifteen positions.

Example of a complete stock number:

5412-266794

The first element, 5412, is the classification code number. The second element, 266794, is the serial number. The first two digits of the classification code number actually form the basic class code numbers 01 to 99.

Four-digit Classification Code Number

The first two digits of a classification code number assigned to 01 and 02 classes indicate whether the item is an aircraft part or an engine part. The third and fourth digits of a classification code number assigned to subclasses 01 and 02 indicate the manufacturer of the item. For example, the classification code 0121 indicates an item with that number assigned is an aircraft part manufactured from Martin Engineering Data (Class 01-K). Classification code 0235 indicates an item with that number assigned is an engine part manufactured from Pratt & Whitney Engineering Data (Class 02-H).

The first two digits of the classification code numbers of Classes 03-A, 03-B, 03-C, 03-D, 03-F, 03-G, 03-H, 03-I, 03-J, 03-K, 03-M, 05-A, 05-C, 05-D, 05-E, 05-F, 05-G, 11-D, 11-E, 16-D, 18, 19-C, 19-D and 32 indicate the classification of the item. The third and fourth digits of the code identify the item either to manufacturer or to a certain category of items within the class. The third and fourth digits of the code for class 32 items identify the manufacturing company. For example, the classification code 4206 indicates that an item with that number assigned is a class 03-C2 item manufactured from Breeze Engineering Data. Classification code 4305 indicates that an item with that code number is a Class 03-D item manufactured from Bendix Engineering Data. Classification code 1953 indicates that an item with that code number is a Class 19-D item falling into the "Galley Equipment and Utensils" category of items.

The classification code number for all classes except those listed above indicates the classification of the item. No information will be contained in the classification code numbers of these classes to identify the manufacturer.

Serial Number Portion of the Stock Number

The serial number for the 01 and 02 Classes and for Class 03-A, 03-B, 03-C, 03-D, 03-E, 03-F, 03-G, 03-H, 03-I, 03-J, 03-K, 03-M, 05-A, 05-C, 05-D, 05-E, 05-F, 05-G, 11-D, 11-E, 16-D, 18, 19-C, 19-D, and 32 will be the manufacturer's part number.

In cases where the manufacturer's part number exceeds fifteen positions or where no part number has been assigned, or when two or more items are carried under the same part number (except items in Class 03-E), a special assigned serial number must be used. The special assigned serial number consists of the arbitrary letters "AAF"* followed by a number of not less than six nor more than twelve digits. (*In this instance, the letters "AAF" do not represent the initials of any word or of any branch of the Armed Forces.)

For class 32 items where the manufacturer's part number exceeds fifteen positions or where no part number has been assigned, or when two or more items are carried under the same part number, a special assigned serial number must be used. The special assigned serial number will consist of the arbitrary letters "XM" followed by a number of not less than five nor more than thirteen digits.

The serial number portion of the stock number for those items carried in class 15 and subclass 17-D will be as follows:

Class 15 Items. The serial number portion will be the Technical Order number, the manufacturer's service bulletin number, or the manufacturer's part number assigned to the kit.

Subclass 17-D Items. The serial number portion will be the Technical Order number that has been assigned to the kit in accordance with T.O. 00-30-1.

The serial number portion of the stock number for the balance of the classes will be the same as those shown in current supply catalogs and supply catalog addenda.

For additional information on the Air Force stock number system refer to: T.O. 00-35A-8, titled "Air Force Stock Number System."

As was mentioned previously, the serial part of the stock number in most cases will be the manufacturer's part number. This is a number assigned by the manufacturer and corresponds to the number used in his basic drawing. It also corresponds to the nomenclature of the item being manufactured. Example: A382-054 is the serial element of a stock number for a carburetor-restriction diaphragm manufactured by Holley Carburetor Company. The number A382 is the Holley Company part number. The 054 is a suffix to the part number. This suffix is to show the distinguishing feature of an item by a symbol or number representing quantity of measurement—the size of a hole, for example, or capacity of a jet in a carburetor fuel injector, or the water column reading in an automatic mixture control.

In order to establish basic principles and rules for obtaining and using part numbers and nomenclature, the Air Force has published T.O. 00-35A-6, titled "Administrative—Part Numbers and Nomenclature." From this Technical Order one can learn the part number filing system that is used on all property records and paper work incident to procurement, requisitioning, shipment, storage, and issue of Air Forces property.

Part numbers may contain letters, numbers, diagonals, period, dashes, and spaces. Since this is so it has been necessary that a filing system be devised in order to file them in a logical manner.

Part Number Filing System

Classes of property indicated in T.O. 00-35A-8, are filed and controlled by a part number. Air Force activities will arrange stock record cards, bin locator cards, and report stock balance changes in these classes in accordance with the part number filing system described below.

Principle. Part number arrangement shall begin on the extreme left-hand position and continue from left to right, one position at a time, until the part number arrangement is determined.

First Position Arrangement. The order of precedence in beginning the part number arrangement on the extreme left-hand (first) position of the part number shall be as follows:

Letters A through Z
Numerals 0 through 9
Note: Letter "O" not used.

Second and Succeeding Position Arrangement. The order of precedence in continuing the part number arrangement on the second and succeeding positions of the part number from left to right shall be as follows:

Space (Blank Column)

Diagonal (Slant) (/) (Signal Corps Numbers Only, Except Class 16-F)

Point (Period) (.) (Signal Corps Numbers Only, Except Class 16-F)

Dash (—)

Letters A through Z (omitting "O")

Numerals 0 through 9

Spaces, Diagonals, Points and Dashes. Spaces, diagonals, points, and dashes shall not appear in the extreme left-hand position of the part number; however, they are found in the second and succeeding positions of the part number and shall take precedence over letters and numerals as indicated in the preceding instructions.

4. USAF SUPPLY CATALOG

The Air Force stores and issues 650,000 items of Air Force technical supply. Up to this point, you have learned how all these items were classified, the stock number system, and the part number filing system. The next part of this section will deal with the publications that list all the separate items. These publications are called **USAF Supply Catalogs.** They were formerly called Stock Lists.

All supply catalog publications are readily identified by the symbol "S" employed as a prefix to the assigned publication number. The assigned publication number is the property class symbol. There is published an individual publication for each AF property class and subclass. For example: The class symbol for bombing equipment, accessories and related parts is 11-A. The supply catalog publication that lists all the items in this property class would be identified as "S-11-A."

AF supply catalogs contain part numbers, standardized nomenclature, regulated item information status and expendability codes, units of issue, unit costs, and stock numbers of AF property in stock, or in process of procurement, and information on items for which disposal action has been directed.

Application, general supply action or action reference phrases and authorities for local manufacture or local purchase and such other supply information as may from time to time be necessary are included where applicable. Illustrations and identifying information are included in supply catalogs (stock lists) for certain classes.

AF supply catalogs are the official item identification lists of AF equipment, supplies, and spare parts. These catalogs are published separately by property class.

Addenda are issued in the supply catalog publication system for the same purpose as supplements, except that addenda are issued as integral parts of the basic publication which they supplement and bear the same number as the basic publication. Addenda are widely used as a means of revising supply catalogs to include numerous items and changes which cannot be economically incorporated in their proper order in the basic lists until the time of reissue.

Identification. As addenda are components of publications, they are issued with revised title pages for the affected publications, each bearing a revised publication date and a "revision strip." Inclusion of an addendum in a publication is reflected on the "A" page in a manner similar to that employed for revision pages.

Supply Catalog (Stock List) Change Notices

AF supply catalog (stock list) change notices are official supplementary publications issued to disseminate important changes and additions in advance of revisions or reissues of AF supply catalog (stock list) publications. These change notices are cumulative; they reflect in each issue the information contained in the previous notices, except that certain one-time announcements and items incorporated in subsequently distributed revisions, addenda, or reissues of supply catalog (stock list) publications are omitted. Each newly issued change notice, therefore, replaces the preceding publication of like category. For reference purposes, supply catalog (stock list) change notices are to be used in conjunction with basic supply catalog (stock list) publications.

Supply catalog (stock list) change notices are indicated by a dash number added to the active related supply catalog, as, for example, "S-04A-1," "S-04B-2," etc. Part number indexes are numbered "S-00-1."

To understand the information that is included in this publication, it will be necessary to learn the codes that are used in the columns as well as the purpose of the columns.

Arrangement

Part Number (if any) is shown under that heading.

Name. The complete nomenclature consists of the description in boldface capital letters, or all the wording under the heading "name" up to the first three dashes. The information following the first three dashes does not constitute part of the nomenclature and should not be used on reports and forms.

Issue Control. Regulated items are indicated by the symbols "HQ" and "SD" and are defined as follows:

HQ—Controlled by Hq., AMC.
SD—Controlled by Specialized Depot.

(For definitions of "Regulated" see AF Materiel & Services Directive 67-40.)

Status. The following codes designate the status of articles as to procurement, storage and issue:

X—Experimental
ST—Service Test
LP—Limited Procurement
S—Standard
SS—Substitute Standard
LS—Limited Standard
(For definitions of above see AR 850-25.)

The following codes designate the status of articles as to expendability:

NX—Nonexpendable
R—Recoverable
NR—Nonrecoverable (Expendable)
XC—Nonrecoverable, Subject to Pilferage
(For definitions of above see AFR 65-38.)

Unit of Issue. Under this heading, it is indicated whether items are issued in quantities of each, by the pair, by the barrel, etc.

Unit Cost. The cost indicated under this heading is expressed in dollars and decimals of a dollar. For example, an item having a unit cost of .105 is ten cents and five mills.

Stock Number. This column is divided into two elements; both make up the stock number. Under "class" is the classification code number. Under "serial" is the assigned number. If no numbers appear under the serial portion then the part number will be used along with the class code number, thus completing the stock number.

Change. New items and changes are indicated by a numeral in the "change" column, and each numeral indicates the addendum wherein the addition or change appeared first. Thus, all items showing the numeral "1" will be those listed in the first addendum.

Margin. Symbols ACT or REF will appear in the extreme right-hand margin of each page. These mean:

ACT—Item of active status, or change on active item, or reactivated item.

REF—Action directives such as "Change to," "Consolidate with," etc.

The arrangement as explained above is not consistent in all supply catalog publications. The same information can be found but the listing of items and information will be in different arrangement. Further discussion of the listing arrangements will be made in this section.

Before the supply catalog publications may be used, it will be necessary to identify the item as to name, part number, and/or the manufacturer of the item to be ordered. This is necessary because the supply catalog publications will have the items listed either and alphabetically, numerically, and in some cases, numerically according to the manufacturer.

5. PROCEDURE FOR USING USAF SUPPLY CATALOG

Identification

To obtain complete identification for individual items of property the following listed sources will be used, in the order named, if applicable:

Name plates, container labels, or tags.

AN and AF Drawings.

Aircraft, Engine, and Accessories Manufacturers' Drawings.

Parts Catalogs in the Technical Order File.

Federal, JAN, AN, AF, and U. S. Army Specifications.

AF Contracts and Maintenance Parts Breakdowns.

Manufacturers' (Commercial) Catalogs.

Handbooks of Assembly and Maintenance Instructions (Technical Orders).

Shipping Tickets or Packing Lists.

Note: The approved sources for obtaining part numbers and nomenclature used on all AF property records and paper work are AF supply catalog publications.

In no case will the classification, other than that established in the appropriate USAF supply catalog or addendum, be considered authentic.

The above listed sources aid in finding information necessary to use the supply catalog publications.

After identifying the item, it is then necessary to determine the USAF property class that the item is stored under.

Classification

Technical Order 00-35A-1 titled "Classification of United States Air Forces Equipment and Supplies" is the publication to use. Another publication that can be used is the "USAF Numerical Part Number Index for Property Classification" which will be used to facilitate determination as to the proper USAF supply catalog in which part numbered items are published.

Procuring

The next step is to obtain the supply catalog that the item is listed in. The publication will be numbered with an "S" before the class symbol. For example: A bombsight is stored in the USAF property class "Bombing Equipment, Accessories and Related Parts." The class symbol for this property class is 11-A. The supply catalog publication for this property class will be numbered S-11-A.

Whenever it is necessary to find out if the publication is the latest issue, T.O. 00-1-1 should be referred to. All supply catalog publications are indexed in this Technical Order.

The next step is to locate the item in the supply catalog publications.

Location

In these publications, the items will be listed either and or alphabetically, numerically, and in some cases, numerically according to the manufacturer.

6. USAF SUPPLY CATALOG SECTIONS

The following are figures and explanations of the different types of supply catalog arrangements.

Note: Each publication will have a table of contents on the front page. From this can be determined the arrangement therein. There is a preface in every publication explaining the supply catalog for that particular class.

It will be definitely advantageous and profitable in terms of a job better done to read very

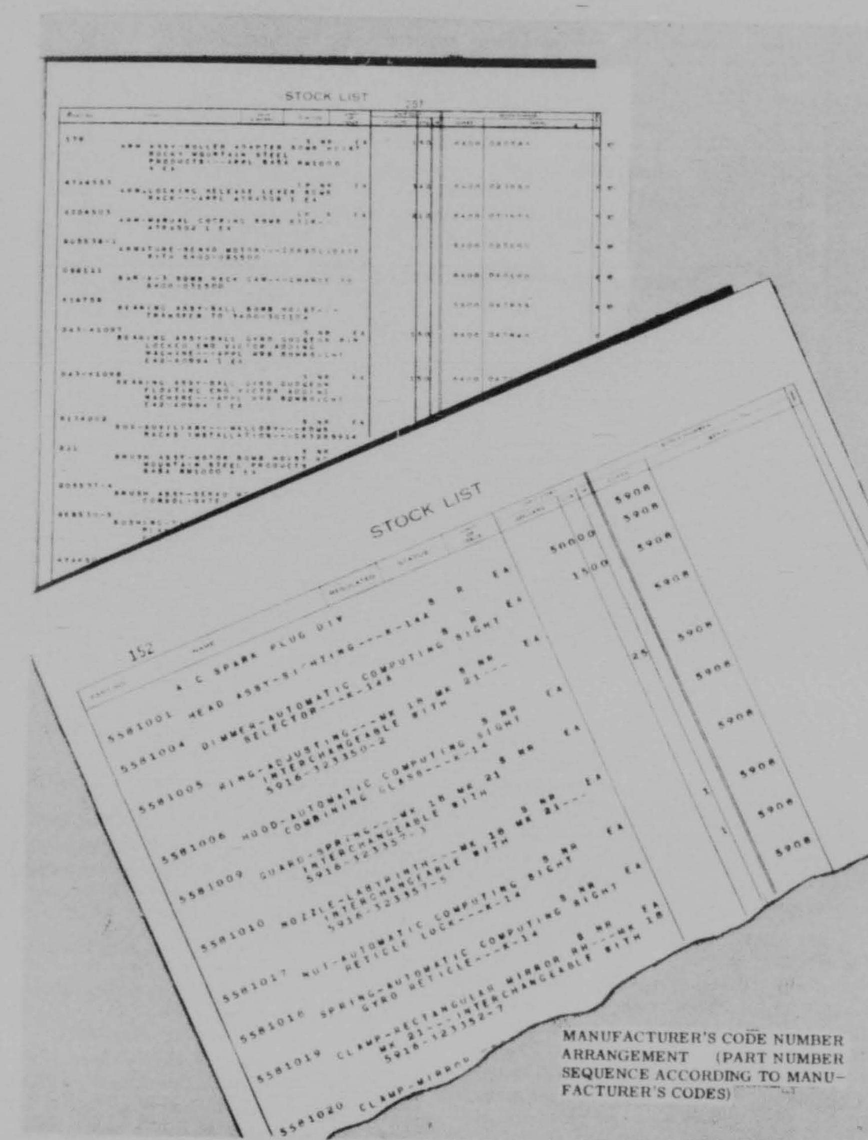


Figure 4-2. Alphabetical Sequence in Stock Number Sequence.

3-20801		6400	856215	32A044-2		6400	856965	
3-20801-1		6400	849020	32A044-50		6400	376885	
3-21119		6400	100125	32A044-51		6400	376887	
3-21119-1		6400	100130	32A044-51R		6400	376490	
3-6738		6400	075000	32A044-52		6400	376889	
3-6864-119		6400	235330	32A044-53		6400	376891	
3-7819-4		6400	058200	32A044-6		6400	045205	

Figure 4–3. Part Number Index.

carefully the important explanations and directions on the pages preceding the supply catalog publications. A thorough understanding and knowledge of these facts will result in an easier, faster, and more accurate performance of various tasks in connection with the publication.

In most supply catalogs there will be three sections:

The basic stock list
Part number Index
Addendum.

Basic Stock List

The basic stock list will be generally one of two types. The first type of arrangement will have the items arranged alphabetically, regardless of the manufacturers of the item. In this type of arrangement, the stock numbers are arranged in numerical sequence; although they do not fall in strict sequence they are in an increasing numerical arrangement.

In the second type of item, arrangement of the articles is first segregated as to the manufacturer of the item. Then the articles are arranged in part number sequence under the class code of the individual manufacturer. (For class codes see T.O. 00-35A-8.) The part numbers will be according to the part number filing system that was explained previously. In this type of arrangement, the serial element of the stock number will be the part number. Figure 4-2 shows the two types of the basic stock list.

Part Number Index

In this section, the part numbers will be arranged according to the part number filing system only. They are cross-referenced to the stock number or the manufacturer's code number. No other information is contained in this section. For other information, it will be necessary to refer back to the basic stock list section. To clarify the above, the following two examples are cited:

Example 1: Figure 4-3 is from the supply catalog whose first section has the items arranged alphabetically, and with the stock numbers in numerical sequence.

This part number index will be used if the nomenclature is unknown and cannot be found in the basic stock list.

After locating the part number, it is cross-referenced to the stock number. Now, knowing the stock number, it is possible to find the stock number in the basic stock list section because the basic stock list section is arranged alphabetically and in stock number sequence. Upon locating the stock number, all other information can be obtained.

Example 2: Figure 4-4 is from the supply catalog whose first section has the items arranged according to the manufacturer's code number and in part number sequence.

In this index, the part number is cross-referenced to the manufacturer's code number only. It then will be necessary to turn to the basic stock list and locate the code number.

After the code number has been found, the part number may be found.

229

PART NO.	STOCK NUMBER CLASS	STOCK NUMBER SERIAL	PART NO.	NAME	STOCK NUMBER CLASS	STOCK NUMBER SERIAL	
9000800G2	5901		9030451G1		5901		
9000801P1	5901		9030452G1		5901		
9000879P1	5901		9030517P1		5901		
9000881P1	5901		9030518P1		5901		
9000883G1	5901		9030604P1		5901

9000996G1	5901		9030690P1		5901		
9000996G2	5901		9030642P1		5901		
9005009G1	5901		9030692P2		5901		

Figure 4–4. Part Numbers–Class, etc.

Note: The part number will be listed according to the part number filing system. The serial element of the stock number will be the part number.

Addendum. Contains item information that has been published after the basic stock list.

The current status of an item is the one indicated in the latest catalog publication, be it a USAF supply catalog, addendum or revisions thereto, or change notice. Upon using these publications, one should always consult the change notice first, then the addendum and basic catalog if necessary. For additional information regarding each type of publication, one should refer to the corresponding preface.

All the above publications referred to are used whenever information is desired on equipment and supplies procured and issued by the United States Air Force.

Whenever it is necessary to find information on the equipment issued and procured by the following technical services, it will be necessary to use the Department of the Army supply catalog and other publications.

Ordnance Department
Signal Corps
Quartermaster Corps
Corps of Engineers
Transportation Corps
Chemical Corps
Medical Department

SECTION III—DEPARTMENT OF THE ARMY SUPPLY

1. DEPARTMENT OF THE ARMY SUPPLY CATALOG

The Department of the Army supply catalog is made up of a separate series for each technical service. The series for each service is identified by a letter symbol. This letter symbol will identify the pamphlets of the technical services.

Letter Symbol	Catalog Series
ORD	**Ordnance**
CML	**Chemical**
ENG	**Engineer**
MED	**Medical**
QM	**Quartermaster**
SIG	**Signal**
TC	**Transportation**

Each series is issued to cover the material normally handled by each technical service.

Each series is issued in sections which often consist of many individual pamphlets. These sections will vary in their content and numbering according to the technical service that prepares them. In general the contents of these sections are as follows:

Section 1: Introduction and Index. This is a guide to all sections of the catalog system of the originating service, with explanation of its content and use, requisitioning procedures, and other necessary general information; it contains the identifying number, and alphabetic listing of titles of each publication. (There is no Section 2, since 1 and 2 have been combined in Section 1.)

Section 3: Major Item Lists. Contains a list of major items, major combinations, and such other items whose basis of issue is generally established by T O&E's, etc.

Section 4: Allowance of Expendable Supplies.

Section 5: List of All Items. This section may be published in several series. The information in each series may be pamphlets that list the standard hardware, bulk materiel, and miscellaneous items; or part number indices, and pricing guides.

Section 6: Sets, Kits, and Outfits. This section consists of pamphlets listing tool and gage sets and their component parts.

Section 7: Organizational Maintenance Allowances. Section 7 pamphlets are published only for those items of materiel that require issuance of equipment and or spare parts to using troops for the operation of the major item, and the performance of organizational maintenance. These pamphlets list the authorized allowances of spare parts and equipment that are issued with the major item.

Section 8: Field and Base Maintenance Spare Parts and Equipment. These pamphlets are published only for those items of materiel that require spare parts for field and or base maintenance. These pamphlets contain stock guides of extra major items, spare parts and equipment estimated to be required by field and base maintenance and supply operations.

Section 9: List of all Parts or List of all Service Parts. This section consists of pamphlets listing alphabetically each part and assembly comprising a major item. The assemblies and subassemblies are generally illustrated. It is used for identification purposes and not for requisitioning purposes.

Section 10: Section 10 and all other sections will be used as the technical service desires.

The above numbered sections will be identified by the letter symbol of the technical service. For example: Section 1 is the introduction and index. If the pamphlet is published by the Ordnance Department it will be printed as ORD 1. If the pamphlet is to be the introduction and index of Chemical Warfare Service, it will be recognized by the "CML 1."

Since it will be impossible to discuss fully all the series that comprise the Department of the Army supply catalog, we will explain the Ordnance pamphlets. All the series will be similar in nature, so understanding one will aid in understanding all others.

Note: Before attempting to use any of the technical service pamphlets one should read carefully Section 1 of each technical service catalog.

The Air Force armament officer will have to know how to use the pamphlets of the Ordnance supply catalog since much of the equipment he will use is procured and issued by the Ordnance Department.

2. ORDNANCE PROPERTY CLASSIFICATION

The large number and variety of items designed, procured, stored, issued, and maintained by the Ordnance Department necessitates the segregation of these items into nineteen major classifications. Each classification is identified by a letter (Group A, Group B, etc.). This letter is called the classification letter symbol.

Indicated below are the types of materiel assigned to each of these lettered groups.

Group A: Automatic weapons

Group B: Small arms, hand arms

Group C: Light and medium field artillery

Group D: Heavy field artillery

Group E: Railway artillery

Group F: Instruments used for range finding and for control and observation of fire.

Group G: Armored, half-track, and scout cars, motor carriages.

Group H: Standard hardware

Group J: Common tools, machines, and tool appurtenances.

Group K: Materials required in the cleaning and preservation of ordnance general supplies and ammunition.

Group L: Targets and target material.

Group M: Electrical apparatus units and parts.

Group N: Units of equipment, and material not otherwise classified such as, maneuvering material, power plants, reconditioning outfits, ammunition surveillance equipment.

Group P: Ammunition for medium and major caliber seacoast artillery.

Group R: Ammunition for minor and medium caliber field artillery.

Group S: Bombs, mines and torpedoes for aircraft.

Group T: Small arms ammunition.

Group Z: Captured foreign materiel.

Group OGS: Obsolete general supplies.

Within each lettered group, each major item or category of tools or supplies, is assigned to a numbered subgroup which, when combined with the major classification letter symbol, serves as a classification code. Subgroup numbers are assigned consecutively beginning with "1" upon accession of a new type item into the system. Thus, the pistol, automatic, cal. .45, M1911, being a hand arm, falls into letter group "B." When this materiel was originally classified as standard, the next subgroup number in sequence was "6." This number combined with the letter of the major classification forms the SNL classification code "B-6."

Any supply pamphlet issued by the Ordnance Department on the pistol, automatic, cal. .45, M1911 will be identified by the classification code "SNL B-6."

From the explanation above, it then follows that every major item procured by the Ordnance Department will have its own SNL classification code. Therefore the SNL classification code will designate the piece of equipment.

The numbered sections (Section 1 and 2 introduction and index, etc.) will designate the kind of information that will be contained within the pamphlet. For example, Section 7 "Organizational Maintenance Allowances" lists the authorized allowances of spare parts and equipment that are issued with the major item. When this numbered section is combined with the SNL classification code, it will be a listing of spare parts and equipment for a specific item.

A pamphlet titled "ORD 7 SNL B-6" will be the organization maintenance allowances (Section 7) authorized an organization for the pistol, automatic cal. .45, M1911 (SNL B-6).

A pamphlet that lists the authorized spare parts and equipment for the above mentioned weapon for field and base maintenance would be identified by "ORD 8 SNL B-6" titled "Field and Base Maintenance Spare Parts and Equipment" for the pistol, automatic, cal. .45, M1911."

A "List of all Parts" for the pistol, automatic, cal. .45, M1911 will be identified by "ORD 9 SNL B-6."

A separate pamphlet is published for each group in order that an individual may find what items are included therein. The pamphlet for Group A will be published as "ORD 3 SNL A-1" titled "Major Item Lists for Group A."

For Group B the pamphlet will be published as "ORD SNL B-1."

The pamphlets in Section 3 (ORD 3) will list all the items that have been segregated into the various lettered groups.

ORD 6 "Sets, Kits, and Outfits" itemizes the individual items that comprise sets, kits, and outfits that are authorized by T O&E's, T A's, etc. For example: T O&E's state that an organization is authorized a "Tool Set, Unit Equipment, Second Echelon Set No. 1";

THIS PAGE IS DECLASSIFIED IAW EO 13526

the pertinent catalog pamphlet. ORD 6 SNL G-27, section 2, enumerates the components of the set in detail.

The other sections that are used by the Ordnance Department are:

ORD 10—Tool, Load and Supply Guides. This section is composed of separate pamphlets, each of which lists the tools and supplies required by a particular ordnance unit for its assigned maintenance and or supply mission. Example: ORD 10 SNL N-257, Tools and Supplies for Ordnance Maintenance Company, Air Force. ORD 10 SNL N-20, Tools and Supplies for Field Maintenance Post, Camp, and Station Ordnance Shops.

ORD 11—Ammunition. This section consists of pamphlets listing ammunition, demolition materiels, bombs, mines, etc. Example: ORD 11 SNL S-1, Bombs, Aircraft, All Types.

ORD 12—Obsolete General Supplies. This section is composed of pamphlets listing major items that have been classified obsolete by official action. Example: ORD 12 OGS-1, Obsolete Major Items.

ORD 13—Items Common to two or more Major Items. The pamphlets of this section list parts and equipment that are common to two or more items of ordnance materiel. One pamphlet is published for each lettered group, listing parts and equipment common to more than one major item within the group. Example: ORD 13 SNL A-19, Items Common to Two or More Group A Materiel.

ORD 13 SNL M-5—Items Common to Two or More Groups. This pamphlet lists parts and equipment that are common to major items that are not classified in the same lettered group.

ORD 14—Interchangeability List. This section lists major assemblies used in automotive materiel. By the use of charts, shows application and interchangeability of these major assemblies.

ORD 15—Cross Reference Lists. These pamphlets provide a cross reference of ordnance and manufacturers' part and drawing numbers to the assigned stock numbers.

ORD 16—Captured Foreign Materiel. This section lists the items of captured enemy materiel which may be used for training or for donation.

In ORD 1 Introduction and Index all pamphlets that have been distributed are listed both alphabetic and numerical. Any published pamphlet can be found if the procedure below is followed. For instance, to determine which publication lists the spare parts and equipment for the pistol, automatic, cal. .45, M1911 for a squadron,

Obtain: ORD 1—Introduction and Index.

Locate: Locate the nomenclature of the materiel on which a pamphlet is desired in the alphabetical list and obtain the pamphlet (SNL) number.

Locate: Locate the pamphlet number in the numerical list. The numerical list will have the SNL number listed numerically according to the Group. (Group A, Group B, etc.) The SNL number is followed by the catalog designation (ORD 7, ORD 8, ORD 9). ORD 7 is titled "Organizational Maintenance Allowances." Since this section lists the authorized allowances that are issued with the major item, this will be the one used for a squadron. The pamphlet title is then ORD 7 SNL B-6.

Each ORD 7 pamphlet contains:

An alphabetical list of the spare parts by item name giving the quantities (stock levels) which are maintained by using organizations for performing organizational maintenance.

An alphabetical list of the tools, equipment, sighting equipment, cleaning and preserving materiels, and instructional aids which are authorized units equipped with the major item.

SECTION IV—SUPPLY PUBLICATION CHANNELS AND AUTHORIZATION

1. SUPPLY PUBLICATIONS

The publications discussed up to this point are the official Department of the Army and the Department of the Air Force publications that will be used only for item identification. These supply catalogs do not explain or establish the system used for stock control; nor do they explain the standardized procedures for the requisition, purchase, receipt, storage, issue, shipment, and accounting for supplies.

The Air Force has published AF Manual 67-1, "USAF Supply Manual" which establishes a uniform system of stock control throughout the Air Force. This volume prescribes standardized procedures for the requisition, purchase, receipt, storage, stock control, issue, shipment, and identification of and accounting for supplies by Air Force organizations.

Other publications that disseminate instructions and information on supply matters such as requisitions and issue, warehouse and depot administration and procedure, safety information, storage, packing, marking, and shipping are the "Air Force Materiel and Service Directives." These publications are issued by the Air Materiel Command.

The Department of the Army has published many field and technical manuals that established a system of stock control for the technical services. To supplement these publications "Supply" bulletins have also been published by the Army. All the Department of the Army publications are listed and indexed in FM 21-6.

2. DISTRIBUTION

We have not discussed the physical setup of the depots that provide a system of distribution. The purpose of distribution is to provide a complete stock of tools and equipment and to maintain in stock predetermined quantities of specified items of frequent issue conveniently located and reserved for issue to a maintenance shop, repair activity, or squadron for use in performing its mission.

Distribution includes the procedures and operations by which supplies are moved—from the time an article is first accepted from a manufacturer or supplier until it is issued to the using unit. Distribution agencies direct and supervise this flow of supplies in accordance with approved policies or directives. Storage or transportation agencies accomplish the physical distribution operation.

In following the basic principles of distribution, one must:

Limit issues to authorized allowances. The flow of supplies in a distribution system is based upon specific estimates of requirements as reflected in authorization tables and upon anticipated special needs. (If excess quantities are issued without authority they will not be reflected in supply planning and disruption of the supply plan will result.)

Limit stocks to minimum requirements. Large stocks which do not move increase the initial cost and also increase storage, maintenance, and handling costs. Aircraft, weapons, and ammunition which cannot be procured readily in time of an emergency may be held in reserve. (As a rule, lower echelons should have balanced stocks sufficient for their needs but not so great as to impose a storage burden or to lessen mobility.)

Decentralize operations. Military installations must be able to call directly on depots without having their requisitions previously edited and delay imposed by intermediate agencies. (Decentralization is essential not only to speed up supply operations but to place responsibility in the hands of the agency charged with the distribution of supplies.)

Standardize procedures. Standard procedures are necessary to the orderly handling of our vast complex of supplies in the distribution system; troops must be able to follow standard supply procedures wherever they are stationed.

Serve the combat forces. Supplies become effective when they are issued to combat forces; the objective must be to have adequate quantities located in close proximity to

THIS PAGE IS DECLASSIFIED IAW EO 13526

the combat troops so that the supplies may be issued promptly as needed.

The distribution of Air Force supplies is accomplished through Air Force supply channels. The Air Materiel Command is the Air Force agency charged with the procurement, storage, and distribution of Air Force supplies. Distribution is made through Air Materiel area depots, Air Force specialized depots, and Air intransit depots. Headquarters, Air Materiel Command, prescribes the levels of supplies established within the Air Force supply system. That headquarters is also charged with the responsibility of establishing supply procedures of the Air Force.

Common items of supply are distributed to the Air Force through Army supply channels which include general distribution depots, technical service or branch depots, reserve depots, and the various types of theater of operation depots. Levels of supply within the zone of the interior and those authorized for the several theaters are prescribed by the Department of the Army. Regulations governing supply procedures and techniques are prepared by the technical services and are approved and issued by the Department of the Army.

3. AUTHORIZATION TABLES

Authorization tables form the basis of issue of all supplies, both common and Air Force technical supplies, required by the Air Force in equipping an organization, an Air Force base, or an individual airman. Those authorization tables which will be considered in this section will be limited to the three most common in Air Force operations and which form the basis of initial supply to an organization, an Air Force base, or an individual. They are: (1) Tables of Organization and Equipment (T O&E) (2) Table of Allowance 20-1 and (3) Table of Allowance 21.

Tables of Organization and Equipment

Tables of Organization and Equipment which will be referred to hereafter as T O&E, prescribe the organic structure and equipment of military units, the organization, strength, and functions of which are not subject to frequent change.

At the time a squadron is activated, the activation orders specify the T O&E under which the squadron is to be organized and equipped. This T O&E then becomes the authority for issue to the squadron of all the items of equipment it lists. The equipment listed in the table is all essential equipment and it does not include any items that might be called "luxury" items. Desks listed are field desks; chairs are folding chairs. While the squadron is in garrison, the commander will probably draw from base supply, on memorandum receipt, articles such as desks, chairs, mess equipment, etc. This equipment which the squadron has borrowed from the base is known as post, camp, and station property since it is authorized for the base by a Table of Allowances. Before the squadron moves, it must turn in all this post, camp, and station property.

The Chief of Staff, United States Air Force, has responsibility for the preparation of T O&E's for units assigned to the Air Force. Likewise, the Chief of Staff, United States Army is responsible for the preparation of T O&E's for the Army.

Commanders of any Air Force unit may recommend changes on any of these tables to the Air Materiel Command.

T O&E's fall into one of four categories: normal or standard, special, tentative, and restricted. Each of these tables may be identified by the serial designation in the upper right-hand corner. Normal tables are designated by numbers only, while special, tentative, and restricted tables have letters S, T, and R respectively as suffixes after the number. For example: 1-67 is a normal table, and 1-167R is a restricted table.

Standard Tables. Standard tables are tables of normal and general application and are the ones under which most units will be organized. They have been formulated through tests and experience, have proven satisfactory, and have been approved by the Department of the Air Force or Army.

Special Tables. Special tables are used by a unit which has a special mission to perform.

If the special mission is such as to require a drastic change in both organization and equipment, the unit would operate under a special table. In many cases, however, the special mission would only require extra equipment and not changes in personnel. If these conditions exist, the unit may perform the mission while organized under a standard table by using a special list of equipment (SLOE) to augment its T O&E equipment. An example would be a group operating in the Arctic.

Tentative Tables. When a new-type plane comes out, no one knows exactly what is needed in men and materials to service, fly, and maintain it. Tests are then run on both organization and equipment to determine just what is needed to allow a unit to operate satisfactorily with the new plane. Changes are made as needed, and upon completion of the tests, standard tables are prepared.

Restricted Tables. Restricted tables are known as reduced tables, new tables, or revised tables. They are used by units undergoing processing or reorganization. An examination of an "R" table shows that a unit loses many of its maintenance men and a great deal of its equipment.

Sections. Section I of the tables prescribes the authorized number, grades and qualifications of personnel. Section II of the tables prescribes the authorized allowances of equipment for units organized with the strength as provided in Section I of the table except:

Equipment required for temporary use and for special purpose.

Items of clothing and equipment included in TA 21.

Component parts, spare parts, accessories, and expendable items which are listed in the Department of the Army and Air Force supply catalogs, AF Technical Orders of the 00-30 series, and circulars ~~and~~ bulletins of the various technical services.

Tables of Allowance 20-1. Tables of Allowance 20-1 authorize those items of equipment which are normally required for housing, administration, supply, and servicing facilities at Air Force installations. This includes equipment for that training which is common to, and conducted by, all Air Force organizations and activities.

The form and arrangement of this table conforms as closely as possible as that listed in Section II of the T O&E. Equipment is grouped by technical services and alphabetically within each group and is that normally required to perform the mission of the Air Force installation. Since the allotment of personnel varies for each base, the Tables of Allowances are published with much of the equipment distributed according to the number of men or planes.

Table of Allowance 21 prescribes the allowances for clothing and personal equipment of individuals regardless of where they are serving.

Part I of TA 21 contains general information pertaining to the table; it defines the boundaries of the climatic areas including the arctic, tropics and areas within the United States to which the table refers. Part II lists in detail the clothing and individual equipment authorized to be issued to officers and enlisted men and women within the United States and various theaters of operations. Part III lists the specialized clothing and equipment by organization, and for certain combat operations depending upon the type of terrain or areas in which the operation is being conducted. Part IV contains individual equipment and organizational equipment not otherwise authorized.

SECTION V—DEPOTS

1. USAF DEPOTS

To serve all air bases, Air Force troops, aircraft, and related equipment throughout the United States, there has been created an agency in USAF Hqs. that is responsible for planning and programming the logistics activities of the Air Force. This agency is the Office of the Deputy Chief of Air Staff, Materiel.

This office is guided by three directives. One is the general directive from the Joint Chiefs of Staff to the U. S. Air Force. The second is the specific directive from the Chief of Staff, U. S. Air Force. The third is the directive from the Secretary of Air, especially relative to matters of procurement and industrial planning.

The Deputy Chief of Staff, Materiel, must translate these directives into logistics requirements and outline to the operating agencies what their work must be. The principal operating agency for the Air Force in the field of logistics is the **Air Materiel Command.** The Deputy Chief of Staff, Materiel, is delegated the staff function while the Air Materiel Command has command responsibilities.

One of the primary missions of the Air Materiel Command is to supply and maintain the materiel of the Air Force. In order to serve all the various Air Force organizations, the Air Materiel Command has divided the United States into seven areas. These are called air materiel areas. Each area has an area headquarters. The commander of this headquarters is also the area commander and has command jurisdiction over all AMC activities physically located within the area. He also is charged with the responsibility of logistically supporting all Air Force troops, bases, aircraft, and any other Air Force installation physically located within the area. Each area has an Air Force depot, aircraft storage depots, and in some areas are located specialized depots.

The Air Force depot is also called air materiel area depot. These air materiel area depots receive supplies from the factories. The movement of these supplies is controlled by Hqs., Air Materiel Command. The issue of supplies from the air materiel area depots to Air Force bases depends upon authorized allowances.

The specialized depots generally store and issue supplies that are of one property class or subclass. Regulated items may also be stored and issued from these depots.

Intransit depots do not store or issue supplies but facilitate the loading and unloading of cargo carriers and the segregation, regulation, and storage of supplies.

The types of AF depots found in a theater of operations are:

Base air depots.
Air depots.
Intransit depots.

In this depot system, technical service functions are handled in the appropriate sections of the above listed AF depots.

The Base Air Depot. Within the theater, the base air depot is a large fixed installation normally located in the vicinity of a port. It is designed primarily to handle bulk quantities of supplies and specialized activities not required for the immediate, close support of combat elements. Within the vicinity of the base air depot may be located facilities for aircraft assembly, engine overhaul, aircraft modification, etc. These additional activities will very often be part of the base air depot. The base air depot receives, stores, and issues all AF technical supplies. It includes facilities necessary for maintaining in serviceable condition all of the equipment it uses as well as the equipment and supplies which it handles.

The Air Depot. Within the theater, the air depot includes the administration and facilities necessary for the storage, distribution, maintenance, salvage, and reclamation of supplies and equipment. They are normally in direct support of the combat wings.

Intransit Depots. These installations are normally attached to either a theater air materiel command, air materiel area, base air depot, or air depot and facilitate the loading and unloading of cargo carriers and the segregation, regulation, and storage of supplies. They further serve in assuring that materiel being shipped to AF organizations reaches its ultimate destination. Intransit depots have no maintenance functions. They issue no supplies. They are expediting facilities.

All activities which are peculiar to the operation of the AF in the theater are the responsibility of the theater air commander. There will be established in each theater, one theater air materiel command to which the theater air commander delegates his responsibility for the logistical support of all theater air activities. If necessary, due to scope of the operations, and or geographical conditions,

there may also be established within the theater air materiel command one or more air materiel areas. These will be charged with the responsibility within their assigned geographical areas for depot level of supply maintenance, reclamation, salvage, and the technical supervision over the organizational and field level.

Base air depots are normally under direct control of the theater air materiel command. They serve, but do not command, the air depots of the theater.

There may be several air depots in a theater. If air materiel areas are established, control of the air depots is normally delegated to them. Intransit depots may function directly under the theater air materiel command, or may be attached to an air materiel area, base air depot, or air depot.

The organization of the base air depot, and the air depot, as to types of squadrons and personnel, will vary according to the mission assigned to it and the amount of work to be accomplished.

There are many T O&E organizations that are available for assignment to these depots. A few examples:

Hq. and Base Service Squadron
T O&E 1-562R
Air Repair Squadron
T O&E 1-567R
Air Supply Squadron
T O&E 1-568R
Air Vehicle Repair Squadron
T O&E 1-569R
Air Ammunition Squadron
T O&E 1-564R
Motor Transport Squadron
T O&E 1-998R

The latest trend is to have the air depot handle all supplies, both common and AF technical supplies. The personnel and equipment are provided through the T O&E's for this assignment.

This system is an advantage to the combat wings as they will be dealing with only one depot for all supplies.

The air depot goes to the proper technical service depot to get common supplies; it does not normally get them from the base air depot.

The base air depot will handle only Air Force technical supplies.

2. ARMY DEPOTS

Depots form the backbone of the Department of the Army supply system; they are the means by which flexibility in supply operations can be assured.

At present the Department of the Army operates three types of depots, namely:

The General Distribution Depot.
The Technical Service Depot.
The Reserve Depot.

It is these departments that the Air Force is dependent upon for the distribution of all common supply items used within the Air Force.

The general distribution depot is composed of supply sections corresponding to the various technical supply services of the Department of the Army. For example, each depot has a chemical section, an engineer section, a medical section, ordnance section, etc., whose responsibility it is to procure, store, and issue all classes of supply for which each is responsible.

There are five general distribution depots within the continental limits of the U. S. They are located at Schenectady, N. Y.; Atlanta, Ga.; Columbus, Ohio; San Antonio, Texas; and Ogden, Utah. Each depot is charged with the distribution of Department of the Army supplies to all military organizations, both Army and Air Force, and civilian components of the armed forces within designated assigned geographical areas. In addition, the general distribution depot supplies the various ports of embarkation.

The technical service depots, more commonly referred to as branch depots, are specialized depots which handle supplies of one technical service of the Department of the Army. They include engineer depots, ordnance depots, quartermaster depots, etc., which are administered and operated under the Chief of the Technical Service of which they are a part.

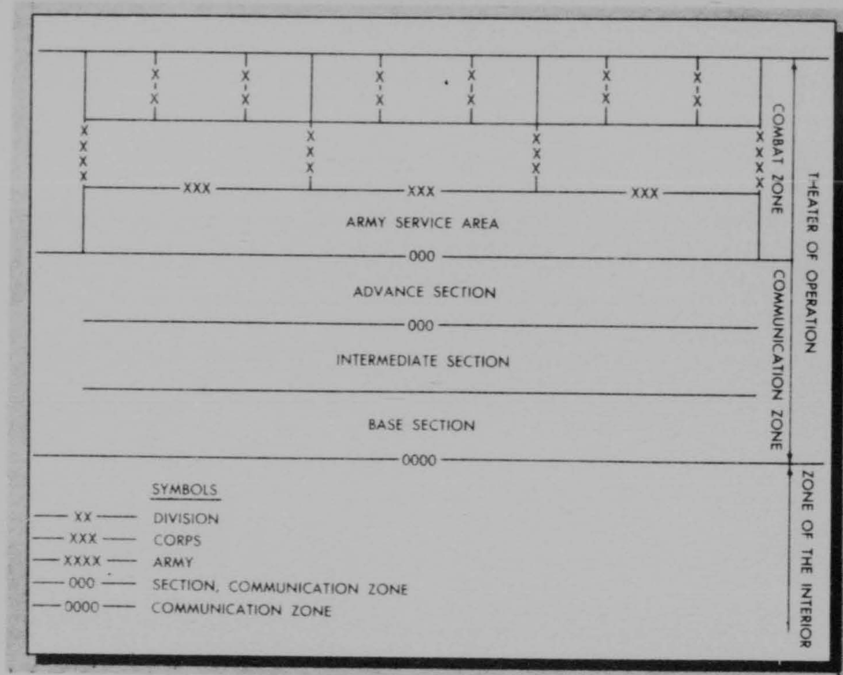

Figure 4—5. Typical Organization of Theatre Operations.

They are used exclusively for the procurement, storage, and issue of items of supply and equipment for which the particular technical service has been charged with procurement and supply responsibility.

The reserve depot, as the name implies, is a standby depot to be used in the event of future mobilization. At present the reserve depot is used to protect surplus property pending disposition; house war reserves, less active items, and various other stocks which may gradually be moved into the general distribution depot. The stocks of active items presently in the reserve depot will gradually be issued to the general distribution depot.

Army depots within a theater of operations are classified within one of the following categories:

Stock carried. Location.
Mission performed.

Considering theater of operations depots classified in accordance with the stock carried, there are two types: the general depot and the branch depot.

The **general depot** procures, stores, and distributes items of supply of two or more of the technical services.

The **branch depot** specializes in the procurement, storage and distribution of supplies of one technical service of the Department of the Army.

Depots classified in accordance with their location in a theater of operations are known as base, intermediate or advance depots, each of which is located within the communications zone of the theater. **Advance depots** are those Army depots within the communications zone, but nearest the combat zone. **Base depots** are located near the rear boundary of the com-

munications zone and generally in the proximity of ports of debarkation. **Intermediate depots**, as the name implies, are those Army depots which lie in the area between the base and advance depots.

Depots classified in accordance with their mission are known as issue, filler, key, and base depots.

An **issue depot** is normally located in the advanced section of the communications zone. It is assigned the responsibility for storing supplies within prescribed levels. It also issues such supplies to meet the needs of armies and other troops in a designated area of the combat zone and to troops and organizations in a designated area of the communications zone.

A **filler depot**, normally located in the intermediate section of the communications zone, is assigned the responsibility for storing the principal portions of theater supplies within levels as prescribed by the theater commander. Filler depots are responsible for replenishing supplies upon request from issue depots.

Key depots are depots assigned the responsibility for centrally storing the entire communications zone stock of selected items of supply and issuing supplies upon approved request.

Base depots are normally located in the base section of the communications zone and are assigned the responsibility for receiving, classifying and storing supplies shipped from ports of debarkation or from local manufacturers. They serve as a warehouse to clear ports of debarkation and for storage of excess theater stocks; they also replenish supplies of specified filler depots. (See Figure 4-5).

Supplies, both common and Air Force technical supplies, are divided into nine classes principally for logistic planning purposes and for supply instructions contained in field administrative orders.

SECTION VI—CLASSES—SALVAGE AND DISCIPLINE OF SUPPLY

1. CLASSES OF SUPPLY

The nine classes are designated by Roman numerals, letters I thru V followed by a capital A in the case of the four special Air Force classes. The following is a brief description of each of the nine classes of supply:

Class I. Supplies such as rations and forage, which are consumed by personnel and animals at an approximate uniform daily rate irrespective of combat operations.

Class II. Supplies and equipment, except Air Force technical supplies and equipment, for which allowances are established by authorized tables and which are not included in Classes IIA, IV, or IVA supplies.

Class IIA. Air Force technical supplies and equipment for which allowances are established by authorized publications and tables.

Class III. Fuels and lubricants for all purposes except aviation fuel and lubricants. This class includes petroleum products such as gasoline, kerosene, diesel oil, fuel oil, and greases.

Class IIIA. Aviation fuels and lubricants.

Class IV. Supplies and equipment, except Air Force technical supplies and which are not otherwise classified. Examples include such material as construction and fortification materials.

Class IVA. Air Force technical supplies and equipment for which allowances are not prescribed and which are not otherwise classified. As an example, additional aircraft with tactical units.

Class V. Ammunition such as small arms ammunition, grenades, mines, explosives such as dynamite, TNT blocks, fuses, and chemical warfare agents.

Class VA. Ammunition used exclusively by the Air Force such as bombs, aircraft rockets, pyrotechnics, aerial mines, special aircraft

THIS PAGE IS DECLASSIFIED IAW EO 13526

machine-gun and cannon ammunition.

The above nine classes in theater of operations may have depots that handle only that special class. Field orders will make reference to the above classes, informing units where that type of materiel may be requisitioned.

2. SALVAGE AND RECLAMATION

Salvage is property that is in such worn, damaged, deteriorated, or incomplete condition, or is of such a specialized nature that it has no reasonable prospect for sale as a unit, or is not usable as a unit without major repairs or alterations. Salvage has some value in excess of its basic material content because it may contain serviceable components or may have value to a purchaser who may make major repairs of alteration. Salvage property is composed of condemned, discarded, abandoned, or captured property including scrap and waste material, nonrepairable property, and abandoned private property.

To salvage means the saving or rescuing of condemned, discarded, or abandoned property and of materials contained therein for re-use, refabrication, or scrapping.

Salvage should be classified as promptly as possible as:

Serviceable.
Unserviceable and repairable.
Unserviceable and beyond repair.

Salvage therefore consists of materiel which can be used for its original purpose, either with or without repair, and materiel which can be converted to a substitute use, or which has value only as scrap for use as raw material. As soon as property is recovered, evacuated, and classified, and is determined to be serviceable or repairable, it should be so designated and removed from the category of salvage.

The movement of captured enemy materiel into supply channels is important, not only for use in the command or for scrap, but also to meet research and training requirements.

Regularly organized field maintenance units of all services will accomplish evacuation in connection with their own maintenance operations. They will also receive and inspect all items within their responsibility and which are recovered or evacuated by other units. After salvage has been collected and inspected, immediate steps, based upon the supply status and condition of each item, must be taken to:

Restore economically-repairable items to serviceable condition within the scope and capacity of the unit.

Evacuate serviceable items to the proper supply establishment.

Evacuate unserviceable economically-repairable items to the proper maintenance organization for repair and return to stock.

Evacuate irrepairable but reclaimable items to the proper maintenance organization for reclamation.

Evacuate uneconomically-repairable items and scrap to designated depots or other collection points.

Reclamation is the process of restoring to usefulness condemned, discarded, abandoned, or damaged materiel, or parts or components thereof, by repair, refabrication, or renovation, and returning such items to supply channels.

Reclaimed property, unless placed in service immediately, will be returned to supply channels. One of the important responsibilities that an armament officer must fulfill is to enforce "supply discipline".

3. SUPPLY DISCIPLINE

In the Service, the practice of saving and conserving is known as supply discipline. Like other disciplines, it should become a habit. It is an evidence of good leadership. Supply discipline is based upon a great military principle as old as history—economy of force. It means making a practice of using equipment and supplies carefully.

In general, the five basic principles of supply discipline which, when carried out effectively, will make all military personnel "cost conscious" are:

Use of supplies and equipment for their intended purposes only.

Proper care, preservation, and timely repair.

Conservation by using only the amount necessary to accomplish the desired result.

Safeguarding against loss.

Prevention of oversupply and hoarding.

Use of Supplies and Equipment for Their Intended Purposes Only

When the government plans to buy a new piece of equipment, experts consider what its purpose will be, and design it to those specifications. Into every item they build certain performance, within definitely stated limits. The manuals on the use of radar, engineer tools, flight control, and bombsight instruments, state the performance capabilities and limitations of each piece of equipment. To exceed, or even to approach, that limit except in emergency, is uneconomic and inefficient.

Proper Care, Preservation, and Timely Repair

Every piece of equipment, every item of supply, has a purpose and a place. If any equipment isn't where it should be, or isn't being used as intended, or isn't in good condition, the personnel responsible for it are not doing their job efficiently. Military personnel are issued the equipment needed to perform their jobs, whether training in gunnery, repairing a tank, driving a truck, piloting a jet fighter, or submerging a submarine. The smart gunner or mechanic learns what his weapons or tools are capable of doing and what their limitations are; he keeps them in good order and handles them only as they were built to be handled.

Following the manuals for protection of property and equipment is another way of practicing economy. When winter or summer oil is called for, when a patch is indicated—that is the time to do the job. Proper care also includes such daily requirements as keeping supplies covered, protecting machines from rust, driving cars, trucks, and other vehicles at reasonable speeds, and piloting planes and ships at their normal cruising speeds except in emergency.

Conservation

Proper utilization of equipment and supplies includes economy of effort. This principle of economy calls for using only the force necessary to do the job efficiently.

Being thrifty doesn't include "sending a boy to do a man's job." One does not use a handjack to raise a building, or a handsaw to hew a forest. No one is expected to tackle a rock formation with a pickax, when dynamite and a mechanical shovel are necessary. Every leader and every man should use just the right amount of equipment and supplies to do the the job adequately and efficiently. That is conservation. Any greater use of materials, time, or manpower is improper utilization.

Safeguarding Against Loss

When supplies and equipment are stored, every precaution for its safekeeping should be taken. Often government supplies are taken, innocently and unthinkingly. The intention on many occasions is to return a borrowed item after it has served the pleasure or requirement of the moment. But often the item is forgotten and never returned. Real economy may be made possible every day by the simple device of asking whether the use of this equipment is necessary to the mission of the individual or unit.

In addition to such unintended leakage is the theft of items for black market sale, or other illegal uses by individuals.

There is no sure cure for this loss, short of a high standard of moral conduct. That cannot be legislated, induced by threat of punishment, or brought about by soft or harsh words. It is a matter for the individual conscience. However, supply personnel can do much to safeguard against loss. This can be done by keeping their records properly, and by storing supplies and equipment so that they cannot be easily drained off, and by using a system of distinctive marking. All members of the armed forces can economize and prevent loss by refusing to connive or assist in removing supplies and equipment illegally.

Prevention of Oversupply and Hoarding

Another thing that everyone can do is to refuse to hoard supplies. A unit should request no more than is needed, and should turn

THIS PAGE IS DECLASSIFIED IAW EO 13526

back to a depot items no longer necessary to the functioning of the individual or the unit.

Hoarding of supplies dates back before the days of Caesar. Once men are in uniform, a considerable number become "pack rats." There is something about the idea of getting in line to obtain a pair of shorts, a couple of pencils, that makes even the most casual individual suddenly become obsessed with the idea that he had better get an "extra" supply. His peculiar reasoning is that there may not be any more when he returns the following day or week.

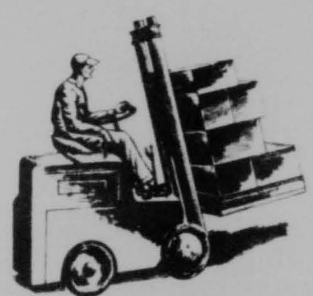
If the "pack rat" tendency applied only to the individual's equipment and supplies, it would be somewhat understandable. However, the idea is extended so that individuals are subject to this mental quirk when they draw supplies for their units.

Tight accounting methods and rigid inspection will correct a large part of the hoarding and thereby reduce the cost of national defense.

Some may say that it should be easy to figure out how many items are available in the military services, and how many are needed for the coming year. But the complexity of the military establishment demands that the supply agencies operate largely on anticipated requirements based on percentages and always projected a year or more ahead. Supply agencies attempt to make these estimates as realistic as possible and as close to the margin of economy as is humanly possible. Sometimes, because of unnecessary damage, unnecessary losses, or "runs" on the supply source, the supply agencies must purchase additional items at the last minute. If allowable, the money comes out of some other allocation for similar material, and somewhere in the process there is a shortage. Or, very possibly, if funds have been contracted for up to 100 per cent, the armed services must do without.

When supplies are lacking, someone must go short. Most often it is the man or the unit at the end of one of the supply line tentacles—and very often it is the man or unit needing supplies most. It is well to remember the wartime cry of the front lines for the food, cigarettes, or ammunition which on occasion did not reach them. Very often someone along the supply line was guilty of overrequisitioning, of hoarding, of misuse, or of carelessness. It all added up to a lack of teamwork and fair play. The men responsible were without a sense of justice to their buddies up front, who had discomfort and death as daily companions.

Proper use, proper care and repair, conservation, safeguarding against loss, and prevention of hoarding are not the only methods of economizing open to everyone in the armed forces. The field is almost unlimited. Proper care of one's health—preventive medicine—and keeping out of the guardhouse or the brig, can save the loss of many days. Safety around barracks, at homes, in vehicles, and planes can pay big dividends. Economy of life and man-hours is as important as economy of equipment and supplies.



CHAPTER 5—BASIC ELECTRICITY

SECTION I—DIRECT CURRENT AND THE NATURE OF ELECTRICITY

1. INTRODUCTION

Man discovered electricity many centuries ago. The ancient Greeks knew that when a piece of amber was rubbed on some fur or cloth, it acquired the property of attracting to it small pieces of paper, dust particles, and other light substances. It is from the Greek word "Elektron," meaning amber, that we obtain the word electricity.

In 1600 A.D., William Gilbert, an English scientist, discovered that many other substances, when rubbed together, possessed the same mysterious property of attracting light pieces of substances, paper, and dust particles. These substances, after being rubbed together are said to be electrified, or to have been given a charge of electricity.

This phenomenon can be proved by rubbing a small glass rod with a piece of silk cloth. Next, the rod is suspended from a silk thread so that it may swing freely. Another glass rod is rubbed with another piece of silk and suspended. When the two rods are near each other they will repel each other.

If a hard rubber rod is rubbed on a piece of flannel and is suspended near one of the glass rods the rubber rod and glass rod will attract each other. From this theory one may readily see that there are two types of charges. A negative charge was obtained with the rubber rod and flannel; a positive charge was obtained from rubbing the glass rod with the silk cloth.

From the foregoing experiment is established a very important rule pertaining to charges of electricity. Like charges repel, unlike charges attract. This basic rule should well be remembered, because the student of electricity will hear it many times.

The experiment with the rods dealt only with static electricity, which is of no value until it can be put to some useful work. Then it is no longer static electricity, but dynamic electricity. One may accomplish with dynamic

THIS PAGE IS DECLASSIFIED IAW EO 13526

electricity such things as fly aircraft, aim guns and turrets, give accurate range data, compute ballistics, and fire guns. It is essential, therefore, that the armament technician understand the important concepts contained in this course of electricity and electronics.

2. CONSTITUTION OF MATTER

Matter is any substance having weight and occupying space. The air a person breathes, the water he drinks, the bus in which he rides, his own body, all constitute matter. All matter is made up of one or more of ninety-two fundamental constituents, such as oxygen, hydrogen, iron, carbon and copper. These are known as elements because they cannot be broken into simple substances by chemical process. Matter appears in true forms. It may be a pure elemental substance; it may be a compound formed by the chemical union of two or more elements; or it may be a mixture of several elements or compounds which are bound together by chemical action. Irrespective of the form in which it is found, all matter can be broken down into molecules. The molecules of a compound always contain two or more atoms, while the molecules of some elements consist of a single atom.

Composition of the Atom

An atom is the smallest particle of an element which retains all the characteristics of the element. Although it is an extremely small particle of matter, the atom can be subdivided into a positive charged nucleus or core, and a cloud of negatively charged particles called electrons that revolve at a very high speed around the nucleus. Figures 5-1, shows that atomic structure of the simplest atom, the hydrogen atom, which contains one electron revolving around the proton which acts as the nucleus. The positive charge on the proton exactly equals the negative charge on the electron so that the atom is electrically neutral. In Figure 5-1$_2$ the nucleus contains two protons, and two neutrons. The charge on the two protons is neutralized by the two orbital electrons spinning around the nucleus. Thus, the neutralization of the positively charged protons is accomplished by the negatively charged electrons and the net charge

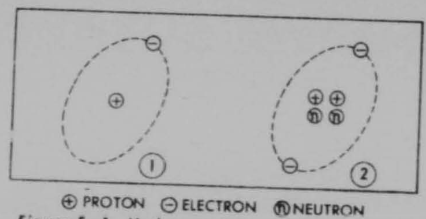


Figure 5—1. Hydrogen Atom, Helium Atom.

of the atom is consequently zero. The presence of the neutrons in the nucleus merely adds to the mass of the nucleus itself. Atoms of other elements are more complex than the two simple examples shown here. However, the only difference among the atoms of the several elements lies in the number and arrangement of the protons, electrons and neutrons of which each atom (with the exception of the simple Hydrogen atom) is composed. All atoms are electrical neutral since the number of positive charges always equals the number of negative charges. Since all matter is composed of atoms and all atoms are composed of positive and negative electrical charges, all matter is electrical in nature.

3. CONDUCTORS AND INSULATORS

In any material some of the electrons are not tightly held in their orbits. Such electrons, called free electrons, are able to move from one atom to another with relative ease. If a voltage is impressed across a substance, the free electrons are very quickly set in motion, causing a flow of electric current. In many materials such as glass, hard rubber, and porcelain, there are very few free electrons. These materials are known as insulators because it is difficult to force an appreciable electric current through them. In other materials, such as silver, copper, and aluminum there are many free electrons. These materials are known as conductors because an electric current can easily be passed through them.

4. THE ELECTRIC CURRENT

The free electrons in a conductor are moving constantly and changing their position in a haphazard manner. When a battery is con-

nected to the two ends of a copper wire, the random motion of the free electron is directed toward the positive terminal by the attraction of the positive voltage. Although the electrons themselves do not move through the wire at a high speed, the disturbance that causes them to drift along the wire progresses with the speed of light. This action may be compared to knocking down a column of tin soldiers; the soldiers do not move very far, but the initial disturbance travels down the line instantaneously. The battery forces the free electrons to drift from atom to atom along the wire only as long as it is connected. When it is removed, each atom is left with its proper number of electrons since those that were taken from the wire at the positive terminal of the battery exactly equal those that were added to the negative end of the battery. This drift or flow of electrons along a wire is called an electric current. **Since the electrons flow from negative to positive, the current is said to flow from negative to positive.** This statement is in contrast with the older conventional theory which assumed current flow to be from positive to negative. To avoid confusion in this manual, any reference to direction of current refers to **electron flow**, or **electron current flow**.

5. RESISTANCE

Since an electric current is a flow of free electrons in a material, those substances which have a large number of free electrons are able to pass a larger current with a given voltage impressed than can a substance with few free electrons. The measure of the numb[illegible] of free electrons in a material is prop[illegible]r[illegible] called resistivity. For a certain cross section and length, the resistance of a material can be calculated from its resistivity. The resistance of a material of a given resistivity is proportional to the length and inversely proportional to the cross sectional area. A unit in which resistance is deliberately lumped is known as a resistor. A resistor dissipates energy because some of the free electrons which are set in motion by the applied voltage collide with others and generate heat. Since the energy to set the electron in motion was obtained from the power source, the result of the collisions is to cause the resistor to absorb energy from the source. As the temperature of the resistor is increased, the random motion of the free electrons is increased but more collisions take place so that there are effectively fewer electrons able to flow as a current, therefore, the resistance of a material increases as the temperature is raised.

6. ELECTRICAL PRESSURE

The external force which tends to make the electrons move through a conductor is known as the electromotive force EMF. Electromotive force is electrical pressure. A practical example of electrical pressure or EMF is the dry cell, which when connected through a conductor to a door bell, causes current to flow through the bell. How electromotive force is produced is not a matter of concern at this time. However, it should be remembered that dry batteries, such as in flashlights or door bells have electromotive force. The unit of measurement of electromotive force is the volt. The number of volts are measured with a voltmeter, which means nothing more than a volt measure.

7. SUMMARY

From the preceding paragraphs, one should remember the following important points:

Unlike charges of electricity attract.

Like charges of electricity repel each other.

Electricity in motion is the movement of electrons.

Conductors have many free electrons and allow a free flow of current.

Insulators have few f ee electrons and tend to retard the flow of current.

Current in amperes (unit of flow) is the rate of flow of electricity.

Resistance in ohms (unit of resistance) is the opposition which regulates the flow of electrons.

Electromotive force (EMF) in volts is the moving force which causes the flow of electricity.

THIS PAGE IS DECLASSIFIED IAW EO 13526

SECTION II—ELECTROMOTIVE FORCE, CURRENT AND RESISTANCE

1. GENERAL

The relationship between the electromotive force, current, and resistance was discovered by a German scientist, George Simon Ohm, at the beginning of the nineteenth century. The unit of resistance was named in his honor.

The most important principle in electricity is Ohm's law. It is impossible to progress in electrical work of any kind without a clear understanding of this basic law and its application to the more common kind of electrical circuits. Ohm's law can be stated very simply, but considerable study is necessary to understand its application to the various electrical circuits.

2. CIRCUITS

In order to have a flow of current there must be a path, or conductor, in which electrons can move. This conductor must be in a form of a closed loop, thereby providing a continuous path for the flow of electrons from the negative source of EMF back to the positive side. This is known as a circuit. In every electrical circuit where there is a movement of electrons, pressure, and resistance are present and must be considered together in order to understand the circuit clearly. It must be remembered that Ohm's law applies just as much to any particular part of a circuit as it does to the entire circuit.

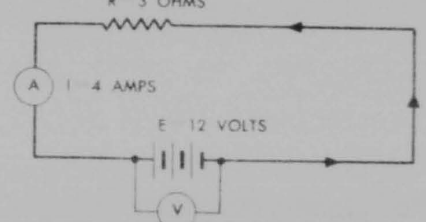

Figure 5–2. Simple Electrical Circuit.

3. OHM'S LAW

Ohm's law gives the relationship between voltage, current, and resistance in an electrical circuit. Ohm's law, simply expressed is as follows: **For any circuit or part of a circuit under consideration, the current in amperes is equal to the (EMF) in volts, divided by the resistance in ohms.** The following equation expresses this relationship:

$$\text{Current} = \frac{\text{Voltage}}{\text{Resistance}}$$

The relationship expressed in the proper units is:

$$\text{Amperes} = \frac{\text{Volts}}{\text{Ohms}}$$

By common consent the following symbols are used:

E = Voltage
I = Current
R = Resistance

Using these symbols, Ohm's law may be written

$$I = \frac{E}{R} \quad R = \frac{E}{I} \quad E = I \times R$$

Application of Ohm's Law

Figure 5-2 is a diagram showing a simple electrical circuit. A wire is connected from the positive terminal of a 12-volt battery to the positive terminal of an ammeter, another wire from the negative terminal of the ammeter to the resistance, and a third wire from the resistance back to the negative terminal of the battery. There is a continuous path for the movement of electrons from the negative end of the battery. A voltmeter is connected across the battery so that its positive terminal connects to the positive terminal of the battery, and its negative terminal to the negative terminal of the battery. The wires connecting the various pieces of equipment are considered of negligible resistance in electrical problems unless a specific value is given.

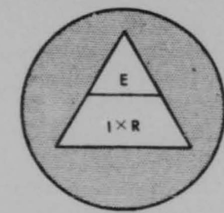

Figure 5–3. (E I x R).

The relationship expressed by Ohm's law is illustrated in the following problems, using Figure 5-3 as an example.

Problem 1—Find the current when the applied voltage is 12 volts and the resistance is 3 ohms.

E = 12 volts (given by voltmeter)
R = 3 ohms

Applying Ohm's law:

$$I = \frac{E}{R}$$

$$I = \frac{12}{3} \text{ or 4 amperes}$$

Problem 2—Find the resistance when the voltage is 12 volts and the current is 4 amperes:

E = 12 volts
I = 4 amperes (given by ammeter)

Applying Ohm's law:

$$R = \frac{E}{I}$$

$$R = \frac{12}{4} \text{ or 3 ohms}$$

Applying Ohm's law:

E = IR
E = 4 × 3 or 12 volts

4. SUMMARY

In applying Ohm's law to a circuit, if two of the values are known, the third can be determined by using the formula in one of the three forms.

Current

The current equals applied EMF divided by the resistance, or: amperes equals volts divided by ohms, or:

$$I = \frac{E}{R}$$

Resistance

The resistance equals the voltage divided by the current, or: ohms equals volts divided by amperes, or:

$$R = \frac{E}{I}$$

Voltage

The voltage equals the current times the resistance or: volts equals amperes times ohms, or:

$$E = I \times R$$

A simple way to remember the relationship between I, E and R is to set them up as shown in Figure 5-3. When it is desired to find an unknown factor, place a finger over the unknown on this form and read the relationship between the other two. Try it.

SECTION III—CIRCUITS

1. GENERAL

In armament and radar work it is often necessary to use two or more pieces of equipment in one circuit. These pieces of equipment may be connected in a number of different ways. All circuits, however intricate, may be divided into three general classes: **series circuits, parallel circuits,** and **series parallel circuits.** In a direct current (DC) circuit the only opposition offered to the flow of current is that due to resistance. The effects of combining several resistances in one circuit will now be considered.

2. RESISTANCE IN SERIES

A series circuit is one in which the resistances or other electrical devices are connected end to end so that the same current flows in

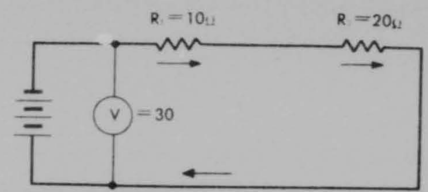

Figure 5—4. Series Circuit.

each part of the circuit. One of the most common circuits is the circuit shown in Figure 5-4.

In this circuit all the current which leaves the battery must flow through R1 and R2 and back to the source. In the current shown in Figure 5-4, the opposition to the current is the sum of all the individual resistors which are in series. Thus a 10-ohm and 20-ohm resistor connected in series make a total opposition of 30 ohms. This gives a law for the series circuit: In a series circuit the total resistance is the sum of the individual resistances. Thus for Figure 5-4

$Rt = R1 + R2$

Returning to Ohm's law, the same amount of current leaving the source must return, so in order to determine the current flow one must first find the total resistance which is 30 ohms. The voltage applied to the circuit is 30 volts as observed from the voltmeter. Then Ohm's law is applied: $I = \frac{E}{R}$

$E = 30$
$R = 30$

Then $I = \frac{30}{30}$ or 1 ampere of current.

It is frequently important to know the voltage across any one of the resistors in a series unit. This voltage may be measured with a voltmeter connected across the individual resistors as shown in Figure 5-5, calculated by Ohm's law.

In Figure 5-5, ammeter A will measure the current through the entire circuit and the values of Ea, Eb, and Ec will be the voltage across each piece of equipment. Ea, Eb, and Ec are called the voltage drops, or IR (current resistance) drops. The total resistance of the circuit in Figure 5-5 is 12 ohms.

Three laws of a series circuit, summarized below should be committed to memory:

In a series circuit the total resistance is the sum of the individual resistances.

In a series circuit the same current flows in each part of the circuit.

In a series circuit the sum of the voltages across the individual resistors is equal to the applied voltage.

3. PARALLEL CIRCUITS

In the series circuit explained in the preceding paragraph, only one path was provided through which the current might flow. There is, also a type of circuit which will provide more than one path through which current may flow. These circuits are known as parallel circuits. A parallel circuit is one in which one terminal of each element is connected to a common point to form one terminal of the system, and the other terminal of each element is connected to a second common point to form the other terminal of the system.

In Figure 5-5 the same voltage which is applied to R1 is also applied to R2 and to R3. This is true because the corresponding points of each resistor are connected to the same points, A and b, and the same difference in potential must exist between points "a" and "b" for all three resistances. This illustrates the first law of parallel circuit. In a parallel circuit the same voltage is across each element. (See Figure 5-6.) For Figure 5-6, $Et = E1 = E2 = E3$.

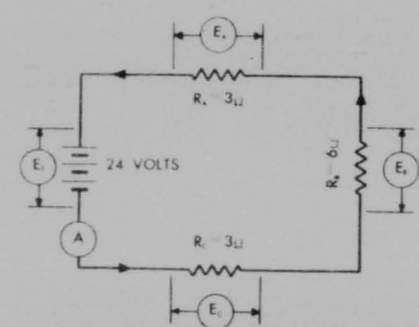

Figure 5—5. Voltage Relationship in Series Circuit.

If an additional path through which the current may flow is provided in a circuit, the total current in the circuit must be the original plus that of the added path. In Figure 5-6, if only R1 is connected to the source it is known by Ohm's law ($I = E \div R$). That current is $6 \div 3 = 2$ amperes. When R2 is added, the same voltage is applied to it as was applied to R1. The current through R2 must equal $6 \div 2 = 3$ amperes. The total current flowing in a circuit is now $2 + 3 = 5$ amperes. When R3 is added, the total current from the battery will be increased, another 3 amperes of current will flow now making the total current flow $2 + 3 + 3 = 8$ amperes. From these results, the following rule for a parallel circuit may be stated: **The total current in a parallel circuit is equal to the sum of the currents flowing in the individual branches.** For Figure 5-6

$It = I1 + I2 + I3.$

Since the total current in the circuit and the applied voltage are both known, the joint or combined resistance of R1, R2, and R3 may be calculated:

$$Rt = \frac{Et}{It} = \frac{6}{8} = .75 \text{ ohm}$$

From this result, another rule for parallel circuits may be stated: The joint or total resistance of a parallel circuit is equal to the applied voltage divided by the total current. In composing the total resistance Rt with the individual resistance R1, R2, and R3, Rt in this case equals .75 ohm and is less than either R1, R2, or R3. In a parallel circuit the total resistance of the elements is less than the resistance of the smallest element.

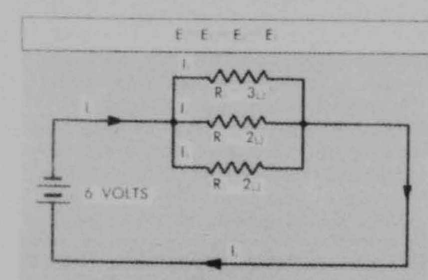

Figure 5—6. Parallel Circuit.

The Three Laws of a Parallel Circuit Should Be Memorized

In a parallel circuit the same voltage is across each element.

The total current in a parallel circuit is equal to the sum of the currents flowing in the individual branches.

The joint resistance of a parallel circuit is equal to the applied voltage divided by the total current.

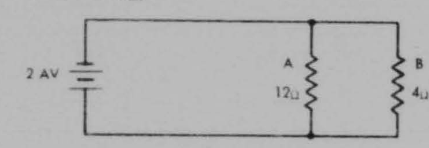

Figure 5—7. Parallel Resistors (unequal).

4. COMBINING PARALLEL RESISTANCES

A method of determining the total resistance of a parallel circuit was shown in the preceding paragraphs. This is satisfactory, providing the total current is known. Usually it is not, and other means must be used for finding the total resistance. The simplest case is that of several equal resistors connected in parallel. To solve this problem, divide the resistance of one piece of equipment by the number of pieces connected in parallel. If two 10 ohm resistances are connected in parallel the joint resistance offered by the combination is $10 \div 2 = 5$ ohms. If three 12 ohm resistors are in parallel $Rt = 12 \div 3 = 4$ ohms, and if five 10 ohm resistors are in parallel $Rt = 10 \div 5 = 2$ ohms. State as a rule: **The joint resistance of equal resistance connected in parallel is equal to one resistance divided by the number connected.**

Unfortunately, all equipment used in electrical circuits do not have the same resistance. Therefore, when different pieces of equipment are connected across a battery they do not all draw the same current. Two unequal resistors connected in parallel are shown in Figure 5-7.

The current through resistor A would be

$$Ia = \frac{E}{Ra} = \frac{24}{12} = 2 \text{ amperes}$$

THIS PAGE IS DECLASSIFIED IAW EO 13526

The current through resistor B would be

$$IB = \frac{E}{Rb} = \frac{24}{4} = 6 \text{ amperes}$$

The total current from the battery is equal to the sum of the current in the branches, or:

$$It = 6 + 2 = 8 \text{ amperes}$$

Ohm's law will give the total resistance offered by the circuit

$$Rt = \frac{E}{It} = \frac{24}{8} = 3 \text{ ohms}$$

Obviously, the rule for equal resistors in parallel could not be used for this circuit as the individual resistors A and B are not equal in value.

For such cases, another method has been found for the calculation of the joint resistance: The resistance of two resistors in parallel is equal to their product divided by their sum. Apply the new rule to the circuit in Figure 5-7

$$RT = \frac{\text{Product}}{\text{Sum}} = \frac{12 \times 4}{12 + 4} = 3 \text{ ohms}$$

which is the same answer found when the applied voltage was divided by the total current.

The product over the sum method may be applied to any two resistors in parallel whether they are equal or not. It is the most common used method of determining the resistances of a parallel circuit. This method may be extended to include three or more unequal resistors in parallel. First, determine the resistance of two of the resistors in parallel; then combine the results of these calculations with one of the remaining resistors by another application of the same rule. In each case the result of the previous calculation is combined with one of the remaining resistances until all the resistances are included. For example, consider the circuit shown in Figure 5-8. In this circuit, three unequal resistors are connected in parallel.

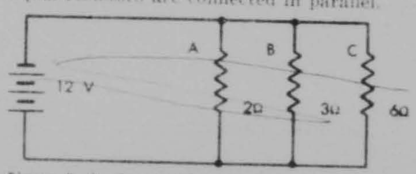

Figure 5-8. Parallel Resistors (unequal).

Applying the rule first to B and C:

$$Rt = \frac{\text{Product}}{\text{Sum}} = \frac{3 \times 6}{3 + 6} = \frac{18}{9} = 2 \text{ ohms}$$

Combine this result (2 ohms) with the remaining resistance (A) of 2 ohms.

$$Rt = \frac{\text{Product}}{\text{Sum}} = \frac{2 \times 2}{2 + 2} = \frac{4}{4} = 1 \text{ ohm}$$

This result (1 ohm) is the total resistance of the three resistors A, B, and C in parallel. This may be proved by calculating the total currents, and from this, the total resistance is calculated by Ohm's law.

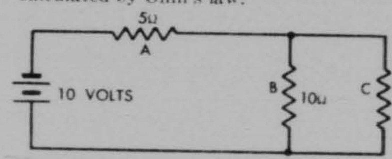

Figure 5-9. Series Parallel Circuit.

5. SERIES PARALLEL CIRCUITS

A series parallel circuit consists of groups of parallel resistors in series with other resistors. Any leg of a parallel group may consist of two or more resistors in series. Series parallel circuits may be solved by application of the rules already given for simple series and simple parallel circuits. To do this, the series parallel circuit is reduced to an equivalent, simplified circuit. Each group of parallel resistors is first replaced by its entire circuit and is then treated as a series circuit. (See Figure 5-9.)

The first step is to reduce the two parallel resistors B and C to an equivalent single resistance. As B and C are equal, divide 10 by 2, which gives 5 ohms as the joint resistance. The circuit is now a simple series circuit of two 5-ohm resistors. The total resistance is obtained by adding resistance A to the equivalent of B and C. This gives 5 plus 5 or 10 ohms as the resistance of the entire circuit. Knowing this, the total current is calculated by means of Ohm's law:

$$It = \frac{E}{Rt} = \frac{10}{10} = 1 \text{ ampere}$$

This 1 ampere flows through resistor A giving a voltage drop of 5 volts ($I \times R$). As the two parallel resistances have the same value, the

1 ampere of current divides equally between the two.

The IR drop across B equals $\frac{1}{2} \times 10$ or 5 volts and across C equals $\frac{1}{2} \times 10$, or 5 volts also. This demonstrates the rule that each element of a parallel circuit is across the same voltage. By following one complete path around the circuit, it can be shown that the sum of the voltage drops is equal to the applied voltage. Starting from the negative side of the battery there is a 5 volt drop in resistor A, another 5 volt drop in resistor B, before reaching the positive side of the battery. Following a path through resistor C will obtain the same result. Care must be taken to follow only one path at a time in tracing a circuit.

It is beyond the scope of this manual to try and solve a complicated series parallel circuits. This can only be done by a series of lectures and demonstrations.

SECTION IV—MAGNETISM

1. NATURAL MAGNETS

The ancient Greeks discovered that a certain kind of rock would attract or pick up bits of iron. They attributed this quality to supernatural causes and made no use of it except to create legends about it. This rock, often called magnetite, is one of the iron ores.

The Orientals learned that if a piece of magnetite were mounted in a horizontal plane and allowed to rotate, it would turn so that one end always pointed toward the north. The Europeans later learned of this discovery and used it as an aid to navigation. Because of this property, magnetite became known as a leading stone or a loadstone. Pieces of ore which have this magnetic property are called natural magnets.

2. ARTIFICIAL MAGNETS

The Europeans soon learned that they could use this natural magnetic ore to make magnets out of iron and steel. Such magnets are called artificial magnets. Artificial magnets are made by stroking a steel bar with a piece of loadstone. Making magnets by electrical means is discussed a little later on.

It has been found that the best magnets are made of steel. Even though iron is more easily magnetized than steel, it does not retain its magnetism so well. Since steel retains its magnetism better than iron, it is said to have greater retentivity than iron. Recent developments in the manufacture of new steel alloys have produced steels of exceedingly high retentivity. Cobalt steel and Alnico are examples of this development.

3. MAGNETIC POLES

If a magnet is dipped into iron filings, the filings will cling to it in tufts. These tufts are longest and greatest at the ends of the magnets and especially at the corners. Near the center, scarcely any filings cling to the magnet. The filings around each end of the magnet seem to line themselves up with lines of some kind of force being radiated from the end. This region about the end of the magnet is called the pole of a magnet.

If a magnet is suspended in air by a string tied about its center, the magnet will turn so that one of its poles points toward the north and the other pole toward the south. This is true of any magnet except a ring magnet. The two poles must be in some way different from each other, since the same pole always points towards the north and the other always points south. Therefore, they are given different names to distinguish them. The pole which points to the north is called the north pole and the conventional marking of this pole is N. The south pole is marked S. Any magnet will act to some extent as a magnetic compass.

If a long magnet is broken at the center and the two pieces dipped into iron filings, it will be found that each of the pieces has two poles, one at either end. It will also be found that one of these poles is a north pole, and one a south pole. The piece which contains the north pole of the original magnet will have a south pole in the end at the break; the piece containing the south pole of the original magnet has a north pole in the end at the break. Every magnet, except a ring magnet, has both a north

THIS PAGE IS DECLASSIFIED IAW EO 13526

and south pole. It may have more than one of either kind of pole, but it must have at least one of each.

4. MAGNETIC FORCE

Since bits of iron may be lifted by a magnet, the magnet must exert a force upon the iron. This force acts at a distance. This fact may be observed by noting the action of a magnet on iron filings. The magnet causes filings to move even though the magnet and filings are not in contact. The force acts through almost any substance, as can be demonstrated by moving a magnet beneath a glass plate on which are sprinkled iron filings. As the magnet is moved, movement of the filings is perceptible. Also, it can be shown that the force is mutual, for a magnet can be attracted to a firmly held piece of iron just as strongly as the iron is attracted to the magnet.

It might be thought that the strength of a magnet could be measured by its lifting power, but this is not true. Various conditions, other than the magnet itself, will vary its lifting power. Some of these conditions are: the kind of iron to be lifted, the shape of the iron body to be lifted, the manner in which the load is applied to the magnet, and the shape of the magnet. The accepted method of measuring the strength of magnets is by their action upon one another.

If a magnet (compass needle) is mounted so that it is free to swing in a horizontal plane, and the north pole of this compass needle is approached with the north pole of a bar magnet, the compass needle will swing until its south pole is as close as possible to the north pole of the bar magnet. See Figure 5-10. Now, if the magnet is reversed so that its south pole approaches the south pole of the compass needle (Figure 5-10), the latter will again swing until its north pole is in the nearest possible position to the south pole of the bar magnet. From these facts, the first law of magnetic forces may be stated: Like magnetic poles repel each other; unlike magnetic poles attract each other.

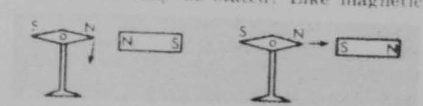

Figure 5-10. Magnetic Polarity.

5. MAGNETIC FIELDS

Since a magnetic pole acts as a distance upon other poles, there must be a space around every magnetic pole in which the magnetic force becomes evident as soon as another magnetic material is placed anywhere within that space. This space about a magnet, in which the magnetic force is evident, is called the field of the magnet or magnetic field.

In one sense, a magnetic field is like a stream of water. The water exerts no pressure until an object is placed into the stream, giving something against which it can push; yet the force is there awaiting an object upon which to act.

A magnetic field may be considered as a force. A force has direction, and so does a magnetic field. A magnetic pole placed in the field would move in the direction of the force. If it were a north pole it would move in one direction, and if it were a south pole it would move in the opposite direction. To find the direction of a field, the polarity of the pole placed in the field must be known. By convention, the positive direction of a magnetic field at any point is defined as the direction in which a free north pole, placed at that point, would tend to move.

The magnetic field at any point exerts a force on a free north pole at that point. Therefore, since a compass needle is acted upon anywhere on the earth, there must be a magnetic field surrounding the earth. The direction and intensity changes from point to point. This field is invisible, but for many purposes it must be indicated. Such representation is made by means of lines of force. If a free north pole is moved, it will trace a line of magnetic force from the north pole of the magnet to the south pole of the magnet, since it is repelled by the north pole and attracted by the south pole. A line of force may be defined as a line whose direction at every point through which it passes is the direction of the magnetic field at that point. Lines of force leave the magnet at the north pole and enter a magnet at the south pole,

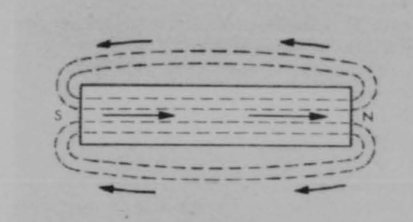

Figure 5—11. Lines of Force of a Magnet.

this being the conventional direction of the magnetic field (Figure 5-11).

For purposes of illustration, four lines of force are shown in Figure 5-11, two on each side of the magnet. Many thousands of lines actually exist for any magnet. Notice that the lines of force do not cross each other. Since the lines of force travel inside the magnet from south to north to complete their path, there are four lines of force at each of the poles of the magnet, and only two lines of force on either side. As the lines of force represent the strength of the magnetic field, it may be stated that the strength of the magnetic field is greatest at its poles. This can be proven experimentally.

6. RELUCTANCE

All magnets do not have the same strength; therefore the fields of various magnets do not contain the same number of lines of force. The number of lines of force must travel outside the magnet.

When a line of force leaves the magnet at the north pole, it must travel outside the magnet, through the air, to reach the south pole because lines of force do not cross one another. Air offers resistance to the lines of force. This resistance to magnetic lines of force is called reluctance. In addition to air, other objects give a certain amount of reluctance to lines of force. For example, copper offers considerable reluctance. In order to reduce the distance that the lines of force of a magnet must travel outside the magnet, and to concentrate the field of the magnet, most magnets used in radio or telephone work are bent in the shape of a horseshoe (Figure 5-12).

7. SHIELDING

Soft iron may also be used to protect an object from magnetic lines of force. This may be accomplished by placing the object in the center of a circle formed by soft iron. Any magnetic lines of force near this combination will take the path of least reluctance through the iron circle, and do not disturb the object. From this example, a statement can be made to the effect that soft iron may be used to distort a magnetic field. Any substance that offers less reluctance than does air to the magnetic lines of force can be used for the same purpose, but not so efficiently as soft iron.

8. MAGNETIC INDUCTION

If a magnet is dipped into iron filings, these filings will cling not only to the magnet but also to one another. This fact is explained by saying that the magnet has made the filings magnets by induction. Such induced magnetism is in most cases only temporary; it vanishes when the inducing magnet is removed. When magnetism has been induced into a substance by the use of another magnet, and this substance retains some of the induced magnetism after the inducing magnet has been removed, this retained magnetism is called residual magnetism. The amount of residual magnetism remaining in a substance depends primarily upon three things: the composition of the substance (the retentivity of the substance), the strength of the inducing field, and the length of time the substance is in contact with the inducing magnet.

Another method of making a magnet by induction is to stroke a retentive substance

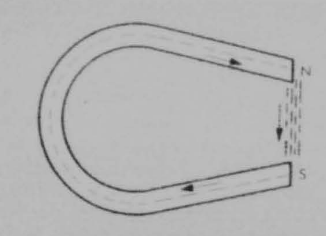

Figure 5—12. Horseshoe Magnet.

THIS PAGE IS DECLASSIFIED IAW EO 13526

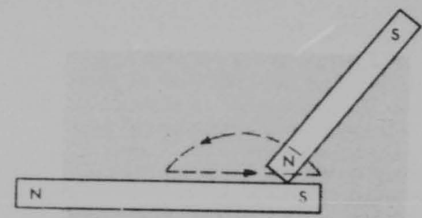

Figure 5—13. Magnetizing by Induction.

with a magnet, following the same direction of stroking each time (Figure 5-13). This method of induction can be understood more easily if the substance is imagined as composed of millions of molecules, each molecule in itself being a tiny magnet. As the north pole of the inducing magnet is drawn over the substance, it attracts the south poles of these molecules and turns them so that they align themselves in one given direction, thus creating a magnet by adding the combined magnetic strength of the individual molecules. Figure 5-14A represents the substance before magnetizing and Figure 5-14B represents the substance after magnetizing. As one portion of the substance is stroked with the north pole of the magnet, a south pole will be induced due to the law of repulsion and attraction of magnetic poles. A north pole will also be induced at the opposite side or end of the substance.

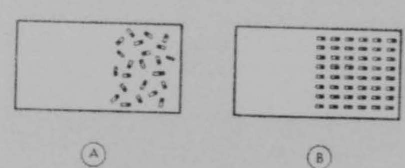

Figure 5—14. Molecular Magnets.

9. PERMEABILITY

It has been shown that soft iron, when placed between two magnetic poles, would allow an additional number of lines of force to pass through a space formerly occupied by air. The ratio of the number of lines of force which pass through a given space when it is occupied by a substance, to the number of lines of force passing through that space when it is occupied by air, is called the permeability of the substance. For all substances except magnetic substances, this ratio is approximately one. The permeability of magnetic substances is numerically always greater than one, and under certain conditions may be in the thousands. Example: Suppose a magnet would produce 100 lines of force through air, and would produce 1,000 lines of force when a soft-iron bar was placed in the field. The permeability of the soft iron would be 1,000 to 100 or 10. Permeability is represented by the symbol (Greek letter) mu.

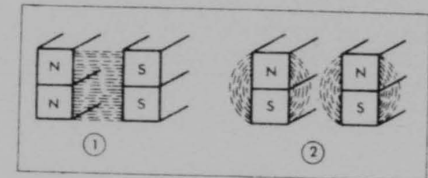

Figure 5—15. Compound Magnets.

10. GENERAL

In practice it is often necessary to place two or more magnets together to obtain a field strong enough to produce the desired results. Such a combination is known as a compound magnet. An example of such a magnet is the generator in the local-battery telephone. This generator uses either two or three magnets. In constructing a compound magnet, all the north poles are placed together, and all the south poles are placed together, thus forcing the field across the air gap. Figure 5-15¹ represents the proper method of placing two magnets together to form a useful field. Figure 5-15² represents the improper method of placing two magnets together to obtain a compound magnet.

Another type of magnet used is known as the ring magnet. This magnet is in the shape of a ring or square, and has no outside field, since the magnetic lines of force make their complete circle within this magnet. The ring magnet has a definite field direction, but no poles. However, if a piece is cut out of the magnet, definite north and south poles are established. The principal use of such magnets is in repeating coils and transformer

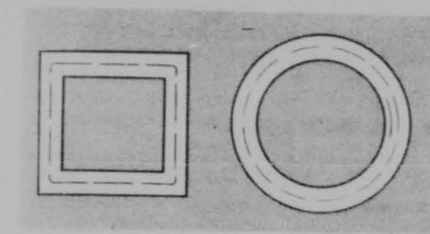

Figure 5—16. Ring Magnets.

cores. Two types of ring magnets are illustrated in Figure 5-16.

A substance that has been magnetized may be demagnetized by excessive vibration or heating. This fact may be explained by the molecular theory. Striking a magnet with a hammer jars the molecules and causes them to move into a jumbled position. Thus, heating or excessive jarring of a magnet will weaken or even completely destroy it. Equipment containing permanent magnets should be handled with reasonable care to prevent demagnetizing. Demagnetizing, either partial or complete, causes errors in measuring instruments and unserviceability in many other types of equipment.

SECTION V—ELECTROMAGNETISM

1. DEFINITION AND EFFECTS

Electromagnetism, in contrast to neutral magnetism, is the magnetic field of force set up around a conductor by the passage of an electric current through it. Every electric current produces a magnetic field which, in the case of a straight conductor, may be represented graphically, as in Figure 5-17. The lines of force about the wire are concentric circles. The intensity decreases with the distance from the conductor, and since the magnetic field is the result of the current flowing in the conductor, the strength of this field is proportional to the strength of the current flowing in the conductor. If the direction of the current through the wire is reversed, the direction of the lines of force will also be reversed.

The presence of a magnetic field around a current-carrying conductor may be demonstrated by placing a freely suspended magnetic needle (a compass) near it. The needle will tend to place itself at right angles to the conductor and parallel with the lines of force. Since a magnetic field, by definition, is the region in which a magnetic needle is acted upon by a force, it follows that the space surrounding the current-carrying conductor is a magnetic field.

In drawings and illustrations, the direction of current flow and the direction of the magnetic field generally are shown. In Figure 5-17, for example, the direction of the current flow in the left-hand drawing, as shown by a cross (arrow feathers), is into the paper. In the right-hand drawing the current is flowing from the paper as indicated by the dot (arrow point) in the conductor. On both drawings, the direction of the magnetic field is indicated by the arrows on the lines of force.

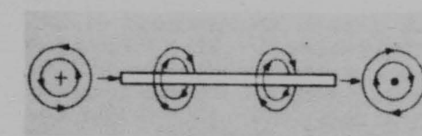

Figure 5—17. Magnetic Field Around a Conductor.

2. LEFT-HAND RULE

After the discovery of the relationship between the current direction and the direction of the magnetic field caused by the current, a simple rule was set up to find the direction of the magnetic field when the direction of the current is known. This rule is known as the left hand rule for determining the direction of the magnetic field about a current-carrying conductor, and stated simply, is as follows: Grasp the conductor in the left hand with the thumb pointing in the direction of the current flow; the fingers will point in the direction of the magnetic field.

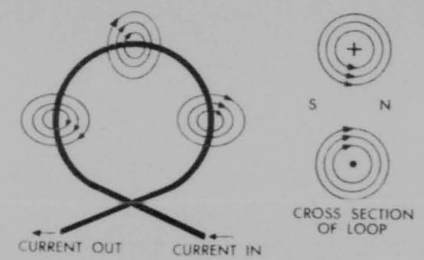

Figure 5–18. Magnetic Field Around a Loop.

3. EFFECT OF BENDING WIRE INTO LOOP

If the straight conductor in Figure 5-17 is bent into shape of a 1-turn loop as shown in Figure 5-18, all of the lines of force which encircle the wire must enter the plane of the loop on the one side and leave on the other. All the magnetic force, which in Figure 5-19 entered the paper beneath the conductor for its entire length, now is confined to the area within the loop. There is still the same number of lines of force produced by the length of conductor, but when bent into the shape of a loop the force becomes concentrated within the loop.

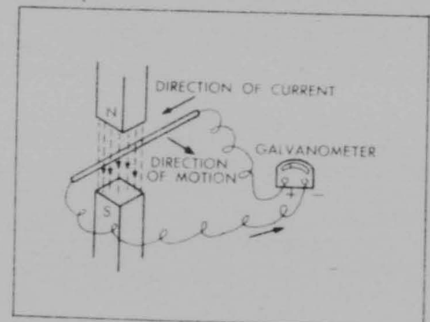

Figure 5–19. Electromagnetic Induction.

4. POLARITY OF SOLENOID

A coil or solenoid carrying a current has a north pole and a south pole just the same as a 2-pole bar magnet, and its polarity may be found by applying the left hand rule for determining the polarity of a solenoid. The rule may be stated as follows: If, direction of the flow of current, and the thumb is extended at a right angle to the fingers, then the thumb will point toward the north pole. If the current is reversed the poles will reverse.

5. ELECTROMAGNETS

An electromagnet may be defined as an iron core surrounded by a coil of wire. The iron in the core is used to reduce the reluctance of the magnetic circuit, and to develop a greater flux that could be developed if no core were used. This is true because the permeability of iron is approximately two thousand times greater than air. The word **flux** is often used in the remainder of the text, and it simply means magnetic lines of force.

A piece of iron can be visualized as containing millions of tiny magnets which, unless otherwise influenced, lie in a haphazard fashion so that they neutralize each other; there is no resultant magnetic field surrounding it. If the iron is exposed to the influence of a magnetic field, the little magnets turn, similar to a compass needle, their "N" poles pointing in one direction and their "S" poles pointing in the opposite direction so that the fields are additive. The degree of magnetization depends upon how completely these magnets can be "lined up." If the magnetizing force is weak, only a part of them will be swung into line, and a weak magnet results.

When the magnetizing force is removed, all of the molecular magnets do not return to their haphazard positions; thus, the piece of iron or steel still has polarity. This remaining magnetism is called residual magnetism. Pure soft iron possesses this quality to only a slight degree, while very hard steel possesses it to a very high degree. In other words, a permanent magnet is one so hard that its particles do not readily swing back to their original positions once they have been influenced by a magnetic field. The tendency of a relay to hold up its armature after the circuit has been opened is caused by the residual magnetism in the core of its electromagnet. Therefore, relay cores are usually made of iron having very little retentivity (soft pure iron or alloys having high permeability and low retentivity).

The rule for determining the polarity of an electromagnet is the same as for a solenoid.

It makes no difference whether the wire is wound in one layer or any number of layers; whether it is wound toward one end and then back over this layer toward the other end, or whether all layers are wound in the same direction. As long as the current circulates continuously in the same direction around the core, the polarity of the magnet will be unchanged.

6. LOSSES IN ELECTROMAGNETS

When the magnetism of an electromagnet is rapidly reversed, that is, when the direction of the lines of force is changed several times in rapid succession by reversing the direction of the magnetizing current, the iron core becomes heated and a certain amount of energy will be expended. This heating effect is due to two causes:

Hysteresis, which is a kind of molecular friction caused by a reversal in position of the minute molecular magnets which iron is thought to possess.

Eddy currents, which are currents produced by an EMF induced in metal when the metal is moved in a magnetic field, or when a magnetic field in the metal changes in intensity.

In order to reduce to a minimum the heating effects (and losses) due to eddy currents, the cores of electromagnets sometimes are composed of bundles of soft iron wires or sheets insulated from each other to hinder the eddy currents. These are known as laminated cores.

7. INDUCED ELECTROMOTIVE FORCE

In the preceding sections the source of EMF was assumed to be a battery. This was done for the sake of convenience and simplicity. However, as a source of commercial electrical energy on a large scale basis, the battery is relatively expensive and unwieldy, and it is necessary to use some other means of obtaining electrical energy in bulk. Probably the most common means of accomplishing this is through the use of the generator, which depends for its operation upon the phenomenon of induction. For the purpose of study, the subject of induction may be divided into two types, electromagnetic and electrostatic. In the present section, however, the student need concern himself only with electromagnetic induction, which may be defined as that phenomenon whereby an electromotive force is induced in any conductor that cuts across or is cut by a magnetic flux; or that is linked by a magnetic field which is changing in intensity. The EMFs generated by electromagnetic induction may be subdivided further as follows: The EMF resulting from relative motion between a conductor and a magnetic field of force; the EMF appearing in one circuit due to the variation of the magnetic field of force in a nearby circuit, known as mutual induction; and the EMF induced in a conductor by a change in the current in the conductor itself, known as self-induction.

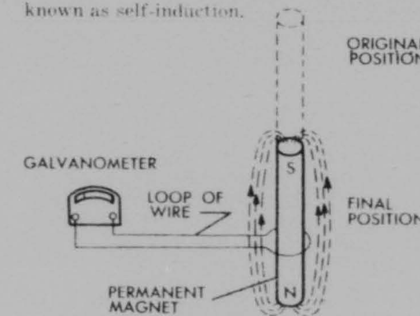

Figure 5–20. Electromagnetic Induction.

8. ELECTROMAGNETIC INDUCTION DUE TO RELATIVE MOTION BETWEEN CONDUCTOR AND MAGNETIC FIELD OF FORCE

When an EMF is impressed on a conductor and a current made to flow through the conductor, this current of electricity produces a magnetic field of force about the conductor. The reverse of this process is true also; a magnetic field can be made to create an EMF and thereby cause a current to flow in a closed loop. This creation of an EMF is accomplished by moving a conductor so that it cuts across lines of force, or by moving the lines of force so that they cut across the conductor. The relative motion is illustrated in Figures 5-19 and 5-20.

In Figure 5-19, if the conductor is moved back and forth between the pole faces so that its motion is parallel to the direction of the

THIS PAGE IS DECLASSIFIED IAW EO 13526

magnetic lines of force and therefore not cutting them, there will be no deflection on a meter connected to the conductor. This demonstrates that there is no induced voltage. As the angle between the lines of force and the path of the conductor is increased, the deflector on a meter increases until the maximum deflection is reached when the conductor is moving at right angles to the field. It may be stated, therefore, that a conductor moving parallel to magnetic lines of force will have no EMF induced in it, while one moving at right angles to the field will have a maximum EMF induced in it. In Figure 5-20 an EMF is induced by keeping the loop stationary and moving the field.

The value of EMF produced by a single wire, moving in a magnetic field, is very small unless the magnetic field is very strong. The same wire can be used to cut the same lines of force 1,000 times, by simply bending the wire in 1,000 loops so that other lengths of it will be exposed to the magnetic field. The wire would then be termed a 1,000-turn coil and would produce the same effect as though a single length of wire had been used in a field 1,000 times as strong as the original field.

Another factor which affects the value of the induced EMF is the speed of the movement. If the conductor is passed through a magnetic field, first slowly and then rapidly, it will be found that a much greater EMF is induced when the conductor is moved rapidly.

Sometimes it is said that electricity is generated by electromagnetic induction. In reality, the mechanical energy which is necessary to move the conductor through the lines of force or flux is transformed into electrical energy. It requires work or energy to move the conductor through the field if the coil is delivering current. A fundamental law of physics is that for every action or force in nature there is an opposite and equal reaction or force. From this law, it might be expected that if the process of induction is reversed, and a current is passed through a wire that is in a magnetic field, a force will be exerted on the wire tending to move it out of the field. That is exactly what happens and if the wire is free to move, it will be displaced from the field in a direction opposite to that required to induce

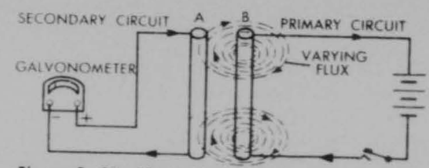

Figure 5—21. Mutual Induction.

an EMF. This action is termed motor action and is made use of in the moving coils of meters and electric motors.

9. MUTUAL INDUCTION

Mutual induction is the production of an EMF in a circuit as a result of the circuit being cut or threaded by a variable flux from a neighboring circuit. In Figure 5-21, circuit A has an EMF produced in it by mutual induction, because the circuit is being cut by the varying magnetic field or flux surrounding circuit B. If circuit B is suddenly connected to a battery, the current flowing through B will cause a magnetic field to build outward and encompass the other wire, A. An EMF, with polarity opposing that of B, will be induced in A during the time the field is building up, because the lines of force are moving outward from B to A. If the battery is then disconnected, another momentary EMF will be induced in A by the collapsing magnetic field. The polarity of the EMF induced by the collapsing field in A will be opposite to the polarity of the EMF induced by the initial expansion of the field. The first effect was caused by the wire being cut by lines of force expanding in an outward direction; the second effect was caused by the wire being cut by the lines of force while collapsing in the reverse direction. This second wire (A) has been termed the secondary circuit and the wire (B), which is used to create the magnetic field, is called the primary circuit. Any change of current in the primary either produces an expansion or contraction of the magnetic field about it. Hence, a current of varying strength will cause the field to alternately expand and contract and induce an EMF, both in the conductor (self-induction) and in neighboring conductors (mutual induction).

The value of the induced EMF depends upon the number of lines of force cut, the

number of turns of wire exposed to the field (if the wire is bent into loops), and the speed or time rate at which the lines are cut. It is thus apparent that the more suddenly the magnetic field is changed, the greater will be the induced EMF.

The induction coil, used in telephone apparatus, operates on the principle of mutual induction. The induction coil consists of two windings of insulated wire wrapped on a core of soft iron strips. The iron core is used to reduce the reluctance of the magnetic circuit.

In the study of induction it should be noted that there is absolutely no transfer of current from one circuit to the other. It is incorrect to say that the current of the secondary is induced from the primary circuit. Current cannot be induced by current; only EMF can be induced. The current that flows in the secondary is the result of the induced EMF.

Caution: A student should be very certain not to confuse magnetism and electricity as they are vastly different forces.

10. SELF-INDUCTION

Self-induction is the induction of an EMF in a conductor or circuit caused by changes in the current flowing through that same conductor or circuit. As current starts to flow through a straight conductor, a magnetic field is built up within and around the conductor. This field may be considered as surrounding the conductor in concentric circles and increasing in intensity, or as cutting the conductor as it builds up or expands. During the period that the flux is increasing in intensity or expanding, a voltage is induced in the conductor. This induced EMF is always in such a direction that it tends to oppose any change in the current in the conductor. When the current in one turn of a coil suddenly increases, the lines of force set up around this turn will expand. In so doing they will cut some or all of the neighboring turns of the coil, thereby inducing in them EMF, which is in the opposite direction to that of the original current. The reverse of this condition is also true; that is, when the current in this particular turn decreases, the field will shrink or contract, and in so doing will again cut all the neighboring turns, but in the reverse direction. The cutting of these turns by the decreasing field induces an EMF. Each turn of the coil acts on other turns, thereby greatly amplifying the effect of self-induction. Therefore, a coil will have much more self-induction than a straight conductor. The effect can be increased many times by the use of an iron core in the coil to decrease the magnetic resistance (reluctance).

Self-induction may be said to be that property of a circuit which tends to impede the introduction, or change, or current flow in a circuit. Self-induction is electrically very similar to mechanical inertia which tends to oppose setting up motion in a body and also tends to keep the body in motion after the force causing the motion is removed. An inductive circuit acts as though it possessed inertia; that is, it resists any change and especially a sudden change in the strength of the current flowing through it.

The EMF that is induced in a coil, when the current is increasing, is in opposition to the applied EMF. Being in opposition to the applied EMF, this self-induced EMF is sometimes called back EMF or counter EMF (CEMF). As soon as the current reaches its maximum value and the field is steady and unchanging, the CEMF will cease. However, the energy required to establish the magnetic field will be returned to the circuit when the current collapses. As the magnetic field collapses on the coil, an EMF is again induced in the coil, but in the opposite direction to that due to the expanding field. This induced EMF will be in the same direction as the original impressed voltage, that is, in such a direction as to prolong the current flow.

11. LENZ'S LAW

During the previous discussion, the conductor in which voltage is induced has been considered as cutting or being cut by the changing magnetic lines of force. It is equally correct to consider that the magnetic field links the conductor, and that any change in this linkage will induce a voltage in the conductor. A transformer is an example of induction by change in flux linkage. The principle of induction, both self and mutual, is expressed by

THIS PAGE IS DECLASSIFIED IAW EO 13526

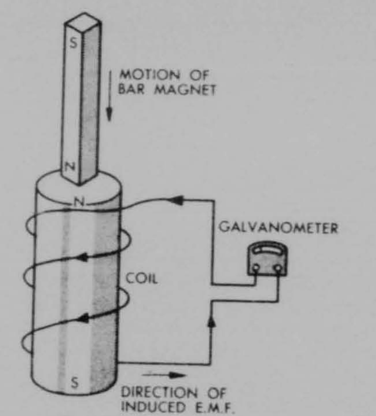

Figure 5–22. Direction of Induced EMF.

Lenz's law. This law is very important in electrical work and should be memorized. It can be stated as follows: **Whenever a conductor cuts across a magnetic field, or whenever the magnetic field linking a conductor changes, a voltage is induced in the conductor in such a direction that, if the circuit is closed, a current will flow and produce a flux to oppose the change in magnetic field.**

In the case of a linked circuit (mutual induction), this current will be distinct and measurable. In the case of self-induction this current will be combined with the current resulting from the applied EMF to produce a net or resultant current. To determine the direction of the induced EMF in a coil, it is necessary to label the coil with a pole that would repel the inducing pole. With this labeled pole as a factor, the left hand rule is applied to determine the polarity of the solenoid, as given in paragraph 9. (Also see Figure 5-22.)

12. MEASUREMENT OF ELECTRICITY

An electrical current may be defined as the movement of free electrons along a conductor. Since electrons are so small as to be invisible, the only means of detecting or measuring electricity is by the effects which it produces.

Effects

These effects are briefly reviewed as follows:

Heating effect. Whenever a current flows through a path offering considerable opposition (resistance) heat is produced. This heat may represent a useless loss of energy, or it may be used to advantage for lighting, cooking, soldering, etc.

Electromagnetic effect. A current produces a magnetic field in its vicinity, as can be shown by the attraction or repulsion of another magnetic field. The area affected in this manner is called the electromagnetic field of the conductor.

Chemical effect. Current, in passing through a chemical solution, will cause certain chemical action to take place. This effect is used in electroplating and electrotyping.

Physiological effect. The physiological effect is shown in the reaction of the human body to an electrical current passing through it.

Use in Measurement

Of the four effects mentioned, the first three can be used for the measurement as well as the detection of electricity. The fourth effect is a physical reaction of the human body and is impractical for precise measurements of electricity.

13. STANDARD MEASUREMENT

The chemical effect, since it is entirely independent of temperature, pressure, mechanical considerations, or physical considerations, is used as the standard with which to define the unit of current. Although used as a standard, the chemical method is not at all suitable for ordinary measurements as it takes time and requires very exact measurements of weight and time.

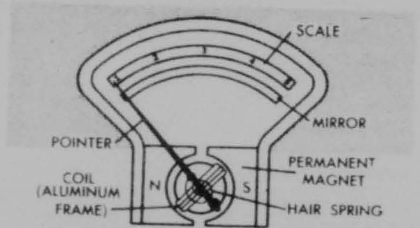

Figure 5–23. D'Arsonval Galvanometer.

Eliminating two of the effects because of their impracticability leaves only the thermal and electromagnetic effects. Since either of these two methods gives almost instantaneous measurements, with the minimum amount of skill necessary on the part of the measurer, virtually all of the common measuring instruments employ one of these two methods in their operation.

14. D'ARSONVAL GALVANOMETER

The D'Arsonval galvanometer, in its simplest form, consists of a coil of wire suspended between the two poles of a permanent magnet. As a current is passed through the coil, a magnetic field is set up around the coil and the coil now has a definite north and south pole in accordance with the right-hand rule. The coil will then turn, attempting to align itself so that its lines of force are parallel to the lines of force between the north and south poles of the permament magnet. Practically all meters employing the electromagnetic effect are based on the principle of the D'Arsonval galvanometer.

In the Weston-type DC meter, shown in Figure 5-23, the D'Arsonval principle of movement is employed. Certain structural improvements are embodied which provide a maximum of ruggedness with a minimum loss of sensitivity. In order to reduce friction, the coil is pivoted on watch jewels. The coiled hair spring tends to keep the coil from turning, thereby providing a force which resists that set up by the reaction between the magnetic fields of the coil and the permanent magnet. The coil and pointer are mechanically balanced so that the instrument may be used in any position. A mirror is placed next to the scale and beneath the pointer so that errors in reading the scale may be avoided.

For a time after the current is applied, the inertia of the coil and the resilience of the hair spring tend to cause the pointer to oscillate about the reading point on the scale. To reduce this tendency, a process called damping is required. The damping process does not interfere with the free movement of the indicator, but reduces the number of oscillations. Air vanes are effective damping devices, but in most meters a closed conducting loop, usually the frame on which the coil is wound, acts as a damper. As the coil moves in the strong field of the permanent magnet, an EMF is induced in the aluminum frame; resulting current produces a magnetic field that opposes the movement of the entire coil structure, thereby acting as a brake to keep the pointer from oscillating. When the pointer is at rest, there is no current induced in the aluminum frame.

In studying the action and construction of DC meters, the question might arise as to the difference between ammeters and voltmeters, since they both employ the D'Arsonval galvanometer principle of movement. In a galvanometer there is no provision for measuring the amount of current flowing through the coil. In this respect, the galvanometer acts more as a detector of current than a measurer. The ammeter is a galvanometer which has been calibrated in amperes so that the amount of current can be read directly from a scale. The voltmeter is a galvanometer calibrated in volts, and is so constructed that the small amount of current necessary to deflect the pointer is in proportion to the voltage being measured.

It must be remembered that when the electromagnetic type of ammeter or voltmeter is used, it consumes energy and becomes, in reality, a part of the circuit being measured. The amount of power consumed in many cases is negligible, and does not materially affect the accuracy of the measurement. However, when it is necessary that there be absolutely no current drain, other devices must be used.

15. AMMETERS

The galvanometer is very sensitive. It is so sensitive that a relatively small current flowing through its coil will drive the needle (Figure 5-23) all the way across the scale. This is because the only opposition to the movement of the coil and pointer is the tension of the coiled spring and the friction of the jeweled pivot. In DC instruments, the current required to give full-scale deflection of the galvanometer may be from 0.0001 to

THIS PAGE IS DECLASSIFIED IAW EO 13526

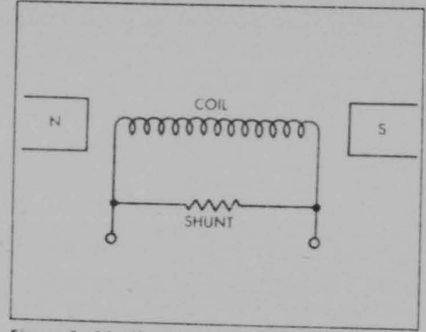

Figure 5—24. Shunt Connection for Ammeters.

0.035 amperes. Since the ammeter is used to measure larger currents than this, and because the ammeter must always be connected in series, it is necessary to shunt most of the current around the coil, allowing only a definite percentage of the total current to pass through the coil of the meter. This shunting or diversion is accomplished by putting a low resistance path in parallel with the coil of the meter. This additional path is called a shunt. The shunt circuit illustrated in Figure 5-24 shows that a parallel circuit is made with the resistance of the coil as one branch, and the resistance of the shunt as the other branch. The amount of current in each branch will depend on the individual resistance and the voltage applied.

By changing the resistance of the shunt, the range of the instrument can be extended so that the ammeter can measure many times the amount of the current necessary for full-scale deflection of the pointer. This is done by providing a shunt having lower resistance than the coil, thereby causing most of the current to flow through the shunt, but allowing enough through the coil to provide a readable deflection of the pointer.

In determining the size of shunt necessary, Ohm's law as applied to parallel circuits is used. For example, in the circuit shown in Figure 5-25, Ra represents an ammeter coil which has a resistance of 0.02 ohms. When 0.01 amperes flows through the coil, the ammeter gives full scale deflection. It is desired to measure 0.5 amperes of current with the meter and the problem is to find the value of shunt, Rs, necessary to increase the range of the instrument from 0.01 to 0.5 amperes. Since the coil itself can carry 0.01 amperes, the amount of current which must flow through the shunt is 0.5 − 0.01 or 0.49 amperes. The voltage drop across the ammeter coil, Ra, is calculated by applying Ohm's law to the circuit. This equals 0.01 × 0.02 or 0.0002 volts. Since the shunt, Rs, is in parallel with Ra, the voltage drop must be the same across the two resistances. Therefore, dividing the voltage drop by the current through the shunt will give the resistance necessary in the shunt 0.0002 ÷ 0.49 = 0.0004 ohms.

If the maximum reading of a meter is changed, the scale of the meter must also be changed, or a multiplying value calculated for converting-scale readings. For example, suppose an ammeter which reads a maximum of 3 amperes is changed by the addition of a shunt, so that the maximum amount of current which can be measured is 30 amperes. The shunt added to the meter has a multiplying value of 10. Hence the readings on the 3-ampere scale would be multiplied by 10 in order to obtain the correct value of current.

16. VOLTMETERS

When the galvanometer is used as part of the voltmeter, the objective is to reduce the amount of current which will flow through the voltmeter to not more than the amount of current required to drive the galvanometer needle all the way across the scale. Since the resistance of the galvanometer coil is not very great, a relatively small voltage applied to the coil would produce enough current for a full scale deflection. Therefore, resistance is connected in series with the coil. This resistance is usually known as a multiplier.

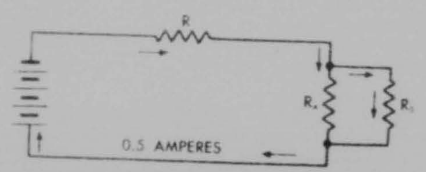

Figure 5—25. Action of Ammeter Shunt.

RESTRICTED

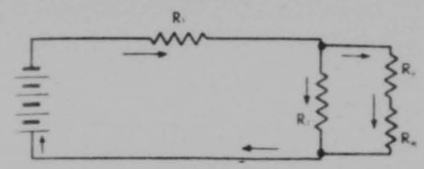

Figure 5—26. Action of Series Multiplier.

The circuit diagram of a multiplier and voltmeter coil, connected to measure the voltage drop across a resistor R_2, is illustrated in Figure 5-26. R_v represents the resistance of the voltmeter coil and R_m represents the resistance of the multiplier. R_v and R_m are in series and form a parallel circuit with the resistor to be measured. Therefore, a large value of R_m in this parallel circuit will force most of the current to flow through the resistor R_2, and will allow only a small value of current to flow through R_v and R_m.

The range of a voltmeter may be changed by varying the value of the multiplier. For example: A voltage drop of approximately 75 volts is to be measured and the only available voltmeter is one with a 10-volt scale reading. This meter can be converted to a 100-volt scale reading by the proper addition of a multiplier. To determine the value of multiplier, the ohms-per-volt value of the meter must be known. This value is usually stamped on the case; the ohms-per-volt value of voltmeter 1-50 being 100. When the ohms-per-volt value is now shown, it may be determined as follows: An ammeter is placed in series with the voltmeter and the amount of current necessary to produce full-scale deflection is determined. With this value, the resistance of the voltmeter is computed. This resistance is divided by the number of volts measured at full scale deflection. Assume that 0.01 amperes of current produces full-scale deflection on a 10-volt scale meter. The resistance of this meter is:

$$R_v = \frac{\text{Full scale reading in volts}}{\text{Current necessary to produce full scale deflection}}$$

$$R_v = \frac{E_v}{I_v} = \frac{10}{0.01} = 1{,}000 \text{ ohms}$$

The ohms-per-volt value of this meter is:

$$R \text{ per } V = \frac{\text{Resistance of meter}}{\text{Full scale reading in volts}}$$

$$R \text{ per } V = \frac{R_v}{E_v} = \frac{1000}{10} = 100 \text{ ohms per volt}$$

With the resistance and the ohms-per-volt value of the meter determined, the value of the multiplier to be used is given by the following equation:

$$R_m = (E \times R \text{ per } V) - R_v$$

(where E is the voltage to be measured)

The value of the multiplier to convert the 10-volt meter to a 100-volt meter is

$$R_m = (11 \times 100) - 1000 = 9000 \text{ ohms}$$

Therefore, it is necessary to add a multiplier of 9,000 ohms in series with the voltmeter to increase the range of this instrument from 10-volt scale to 100-volt scale. All readings then will be multiplied by 10.

It is not to be assumed that the ohms-per-volt method of computing multipliers is the only method to be used. The impracticability of measuring the current flow might prohibit its use in some cases. The application of Ohm's law to series circuits may always be used to determine the value of multipliers.

17. SENSITIVITY OF METERS

The sensitivity of a meter depends on the amount of current necessary to operate the moving element of the meter. The meter requiring the least amount of current for deflection is considered to be the most sensitive.

Since an ammeter is connected in series in a circuit, the voltage drop across the ammeter is a voltage loss. This voltage drop is dependent upon the resistance of the ammeter; therefore, in order to keep this loss at a minimum, the resistance of ammeters is kept at the lowest possible value.

Shunts and multipliers used in the laboratory meters are generally contained in the case of the instruments. Some meters, however, are equipped with outside terminals which provide connections for the use of external shunt and multipliers.

THIS PAGE IS DECLASSIFIED IAW EO 13526

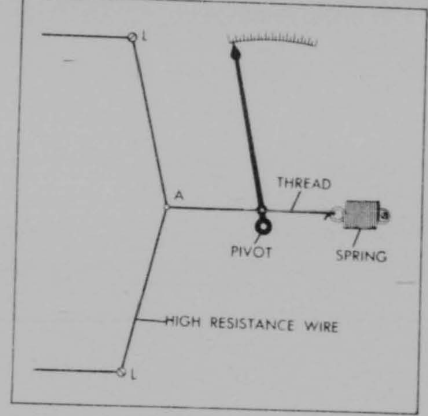

Figure 5–27. Hot-Wire Meter.

18. HOT-WIRE METERS

In the hot-wire meter the thermal or heating effect of electricity is used. The principle of the hot-wire meter is that when a metal is heated it expands, and when cooled it contracts.

The simple schematic diagram of a hot-wire meter is shown in Figure 5-27. The connections to the meter are made at L and L'. As the current flows through the meter, the resistance wire is heated. This heat expands the wire, and the spring pulls the needle over the scale by means of the thread. This is an inexpensive type of meter and is accurate to approximately 10 per cent of the full-scale reading.

19. THERMOCOUPLE METER

The thermocouple is probably the simplest source of an EMF but is of little practical use as a source of electrical energy. A simple illustration of the thermocouple principle is shown in Figure 5-28.

Almost every combination of dissimilar metals will give the thermocouple effect, but some combinations are better than others. Bismuth and antimony, constantan and copper, copper and nickel are combinations that are frequently used as thermocouples.

In a thermocouple meter, the heat is pro-

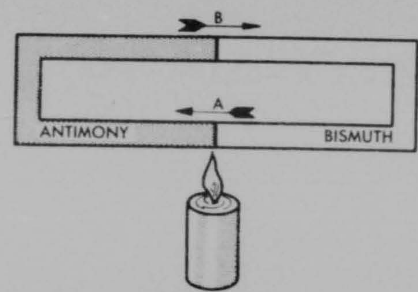

Figure 5–28. Thermocouple.

duced by a current passing through a resistance wire which, being in contact with the thermocouple at the junction of the two metals, heats it and thereby generates an EMF. The EMF generated actuates a meter of the moving-coil type, Figure 5-29.

The thermocouple meter is accurate to approximately 1 per cent. They are more expensive than the hot-wire type, and give much better results. Both the hot-wire meter and the thermocouple meter may be used to measure alternating current or direct current.

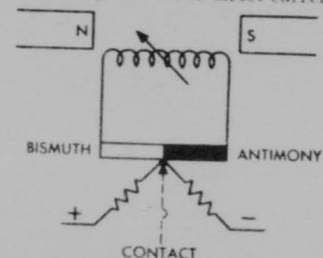

Figure 5–29. Thermocouple Meter.

20. VACUUM-TUBE VOLTMETERS

All of the meters described in the preceding paragraphs require current for their operation. In circuits where the amount of current drain must be at an absolute minimum, the vacuum-tube voltmeter is used. In radio circuits, where the amount of power is very small, the use of the ordinary meter would unbalance the circuit so that the measurement taken would not indicate the true operating conditions.

In the vacuum-tube voltmeter a vacuum

tube is used in connection with a moving-coil-type meter. The vacuum tube acts as an amplifier, drawing a very small amount of current from the circuit and increasing this current a sufficient amount to actuate the meter. For this reason, the meter used in the vacuum-tube voltmeter need not be as sensitive as the ordinary meter and consequently can be more ruggedly constructed.

The vacuum-tube voltmeter may be used for either AC or DC measurements. It can also be adapted for use in measuring current and resistance as well as voltage.

21. POWER AND WORK

Power is an important factor in everyday life, and particularly in the communication field. An understanding of the fundamental physical laws of energy is highly important to the student in solving problems in electrical power.

Energy

Energy is not made or destroyed, but exists in one form or another as a constant amount for the whole universe. This is a fundamental law known as the law of conservation of energy. This purely physical fact should not be confused with the practical fact that great quantities of energy are converted daily into forms no longer available to man, and thus are lost for practical purposes. The expression, "energy is expended or dissipated," is commonly used, and for all practical purposes is often true. Heat energy, electrical energy, mechanical energy, and light energy are some common forms of energy.

Energy can be converted readily from one form to another. This is the law of correlation of energy. An example illustrating this law is the electrical power plant. First, the chemical energy of the fuel becomes heat energy, which the boiler and turbine convert into mechanical energy. The generator then transforms this mechanical energy into electrical energy. In the form of electricity, the energy can be distributed over large areas for the convenience of man. Electrical energy is converted to heat energy by the electric iron, to mechanical energy by the motor, and to light and heat energy by the incandescent lamp. These are only a few examples of the transformation of energy in every-day life.

Force

Force is that which tends to produce motion, a change of motion, or change in shape of matter. Force is "push" or "pull." If a person pushes against a box, it may or may not move, depending upon the amount of muscular force exerted. If this push were exerted against a heavy stone wall, the wall would not move, yet force would be exerted. An example of electrical force is the dry cell. With no circuit connected to the terminals, there is an electromotive force of 1.5 volts between the terminals. This force is insufficient to overcome the resistance of the air between the terminals; therefore, no motion of electricity results. If a flashlight bulb is connected between the terminals, a current will flow through the electrical resistance of the filament. This motion of electricity is due to electrical force.

Work

When a force overcomes a resistance and causes motion, work is done. Regardless of force exerted, if no motion results there is no work done. The operation of a pile driver illustrates mechanical work. When the weight of the driving hammer is lifted against the force of gravity, work is done. This work stores energy in the weight, and while the weight is suspended, ready to drop, it possesses energy. The weight, while suspended, is exerting a force, but is doing no work. When it is released it drops, and upon striking the pile, does work. The amount of work done is measured by the product of the force exerted times the distance the body moves. The unit of work is called the foot-pound. The work done in raising a weight of 1 pound a distance of 1 foot, against the force of gravity, is 1 foot-pound. Raising 10 pounds 10 feet would be 10 pounds × 10 feet or 100 foot-pounds. Force performs work only when exerted through a distance or overcoming a resistance. It makes no difference how much time is required to do work, as long as the work is done. All work, whether chemical, mechanical, thermal, or electrical, can be expressed in foot-pounds. Work is in-

THIS PAGE IS DECLASSIFIED IAW EO 13526

dependent of time, and whether the work is accomplished in one hour or one year, the amount of work is not changed.

Power

Power is the rate at which work is done. To distinguish between work and power, the pile driver is again used as an example. It is necessary to expend considerable energy on the pile to drive it even a short distance. The machine requires considerable work over a period of time to raise the weight. Suppose the machine was designed to raise the weight in 10 seconds, and then it became necessary to change the machine so that the weight could be raised in 5 seconds. It would require twice as much power to raise the weight in 5 seconds. Power is work divided by time. The unit of electrical work is the **joule**, and the unit of electrical power is the **watt**. As a comparison, 746 watts are equivalent to 1 mechanical horsepower.

The discussion of power and work may be summarized as follows:

Energy is the capacity to do work. Work is force acting through a distance. Power is the rate of doing work.

Energy cannot be destroyed, but can be transformed from one form to another.

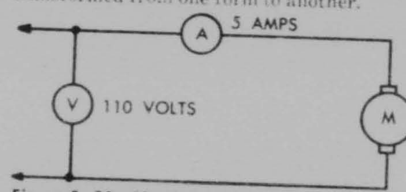

Figure 5–30. Circuit for Measuring Power.

The Watt

The watt is the unit of electrical power, and is equivalent to 1 ampere of current at a pressure (EMF) of 1 volt. Watts = volts × amperes, or DC power = IE. By the use of this formula, the power consumed by an electrtical device can be determined if the current and voltage are known. For example, consider the motor in Figure 5-30. To find the power, one substitutes the readings of the voltmeter and ammeter in the equation. I = 5 and E = 110, therefore P = IE = 5 × 110 = 550 watts. A wattmeter would be used if available, because it reads directly in watts.

Power Losses

The most common loss of power in electrical work is that which is due to the heat developed when current is flowing through a resistance. This heat is usually dissipated into the air and lost for useful purposes, except when the resistance is used for heating. Electric ovens, soldering irons, and filaments of vacuum tubes are examples of this use of heating. Since all conductors have some resistance, transmission lines and circuits should be designed to minimize these losses. An example of equipment where great losses are tolerated to accomplish a given purpose is a home radio receiver. The receiver may consume more than 100 watts of electrical power, yet more than 3 watts of sound power from the speaker would be intolerable. Most of the loss is in heat energy, and it is for this reason the radio sets are well ventilated. Electric motors have losses due to friction and resistance of winding; therefore, the mechanical output can never equal the electrical input. The output of any power consuming device, divided by the input, and multiplied by 100, will give its power efficiency. No machine can be 100 per cent efficient.

Resistance Losses

Resistance losses are an important consideration in communication work. The resistance used must be capable of radiating the heat generated without becoming hot enough to burn insulation or start fires. It is for this reason that resistors are usually rated in watts as well as ohms. This wattage rating indicates the safe wattage in heat that the resistor will radiate in free air without becoming damaged by heat. Resistors are often inclosed and may cause trouble in other parts of the equipment, due to poor radiation of heat.

From the power equation, P = IE, other very important power equation may be derived. Substituting IR for E, the power equation becomes $P = I^2R$. Substituting $\frac{E}{R}$ for I, the power equation becomes, $P = \frac{E^2}{R}$. These three power equations are commonly used.

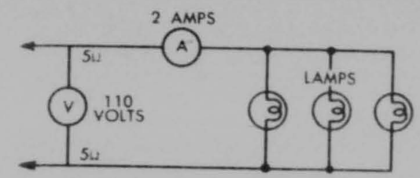

Figure 5–31. Parallel Circuits.

Electricians often refer to Figure 5-31, parallel lamp circuit, to the I^2R losses of a circuit, which is a short way of saying "the power lost in the circuit due to current through the resistance." An example of a practical use of the equation $P = I^2r$ is as follows: In Figure 5-31, the circuit is drawing 2 amperes and the line resistance is 10 ohms. The power loss in the line is to be determined. The joint resistance of the lamps is 45 ohms.

$$P = I^2R$$
$$I = 2 \text{ amperes}$$
$$I^2 = 4$$
$$R = 10 \text{ ohms}$$

therefore, P = 4 × 10 = 40 watts.

An example of the practical use of the equation $P = \frac{E^2}{R}$ is as follows: In Figure 5-32, a 20-ohm resistor is required to reduce the 12-volt battery voltage of a combat car to 6 volts for lighting a 6-volt radio tube. The wattage rating required of the resistor is to be determined:

$$E = 6 \text{ volts}, E^2 = 36, R = 20 \text{ ohms}$$

$$P = \frac{E^2}{R}$$

$$P = \frac{E^2}{R} = \frac{36}{20} = 1.8 \text{ watts}$$

In this example, any standard size of resistor rated at greater than 1.8 watts could be safely used. This equation is commonly used in practice, because all that is required is a voltmeter reading across a resistor to determine how much power is being dissipated in the resistor.

Since power is the rate of doing work or consuming energy, the length of time power is being used is the true measure of energy consumed. It is common practice to purchase electrical energy by watt-hours, watts × hours, or kilowatt-hours, $\frac{\text{watts} \times \text{hours}}{1000}$. A 100-watt lamp requires 100 watts of power for proper operation, and consumes 100-watt-hours of energy in 1 hour. In terms of kilowatt-hours, the lamp uses $\frac{100}{1000} = 0.1$ kwhr in 1 hour, or 1 kwhr for 10 hours of operation.

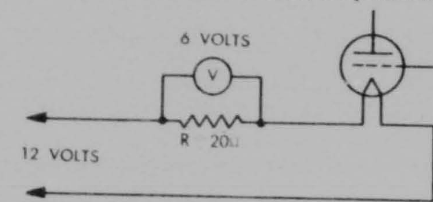

Figure 5–32. Vacuum-Tube Filament Circuit.

22. SUMMARY

The watt is the electrical unit of power, and is equal to volts times amperes.

Heat is a power loss, and is sometimes referred to as I^2R loss, or copper loss.

The output of any machine can never be equal to the input to the machine.

Efficiency is equal to the output of a machine divided by the input to the machine times 100.

The watt rating of a resistor should never be exceeded. Never allow enough current to flow through a resistor so that the current squared times the resistance will exceed the watt rating of the resistor.

Electrical energy is purchased in terms of watt-hours or kilowatt-hours.

23. WATTMETERS

The wattmeter is an instrument used to measure power in a circuit. Since the amount of power present in a circuit is dependent upon both the voltage and the current, a wattmeter must measure current and voltage at the same instant.

The wattmeter is a combined voltmeter and ammeter. It has two fixed coils in series to provide a magnetic field, and a movable coil which turns in this field. The fixed coils are placed in series with the load and may be termed the

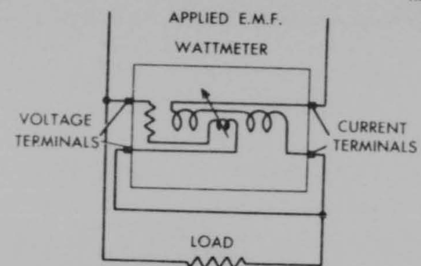

Figure 5—33. Wattmeter.

current-measuring element of the wattmeter.

The movable coil is connected in parallel with the load, and therefore can be considered as the voltmeter element of the instrument. The deflection of the pointer attached to the movable coil is proportional to the value of the voltage times the current, since the force acting upon the coil is the result of the magnetic fields of both the fixed and movable elements. Figure 5-33 illustrates the arrangement of the coils and the connections necessary.

When placing a wattmeter into a circuit, care must be taken that the four terminals are properly connected. Normally, the four binding posts are designated as + and — current-circuit (ammeter) binding posts, and + and — potential-circuit (voltmeter) binding posts.

SECTION VI—GENERATORS

1. GENERAL

A generator is a machine which converts mechanical energy into electrical energy. The mechanical power source may be a steam engine, an internal-combustion engine, or a steam or water turbine. The electrical power may be either direct current or alternating current, depending on the construction features of the machine; yet, in principle, the rotating coils and magnetic field through which they turn are the same for both types of machine. The difference between AC and DC generators is the method by which the current is taken from the machine.

The amount of EMF induced in a conductor passing through a magnetic field depends upon three factors:

The strength of the magnetic field; the number of turns in the conductor cutting across the magnetic field; and the speed of rotation of the coil.

All constructional features in the design of generators provide for a balanced relationship among these three factors.

2. GENERATOR CONSTRUCTION

A generator consists of an outer ring of iron, called the yoke; a cylinder of soft iron

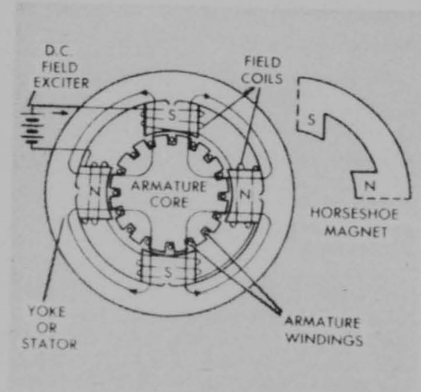

Figure 5—34. DC Generator.

with imbedded coils, called the armature; and a set of collector rings, or commutator segments, with collecting brushes to collect the current. The pole pieces project from the yoke and the field coils are wound on these pole pieces in such a way as to make them alternately north and south poles. The magnetic field, due to the alternate spacing of the poles, divides equally at each pole and, therefore, forms a resultant field made up of the same number of horseshoe magnets as the number

of poles, see Figure 5-34. There must always be an even number of pole pieces.

By winding the field coils on the pole pieces, the permanent magnets are changed into electromagnets, thereby greatly increasing the field strength without increasing the size of the pole pieces. By projecting the pole pieces from the yoke to form horseshoe magnets, the air gap in the magnetic circuit is decreased to the minimum clearance necessary for the rotation of the armature. As air offers much more reluctance to the magnetic field than iron, the air gap should be as small as the mechanical considerations will allow.

The armature consists of the armature coils, core, and collector rings or a commutator. Since the iron core acts as an iron conductor in a magnetic field, it is laminated to prevent the circulation of eddy current. The armature coils are made up of many turns of copper wire. As the number of turns in the loop are a factor in the amount of voltage generated, the greater the number of turns (limited by the increased resistance and dimensions of the machine), the higher the induced EMF will be. The copper coils, because of the weight and centrifugal force acting upon them during rotation, must be supported by the iron core. For mechanical safety and efficiency, the coils are set in slots cut in the core surface and wedged in place with wooden or fibre wedges for strength and support.

Finally, the EMF of the machine as a generator depends upon the speed. High speeds tend to cause mechanical failure because of the centrifugal force, hence speed is limited for safety considerations. If the coil has to move only half as far to cut the same number of lines of force, the speed might be cut in half and the same EMF or power be developed. The insertion of another pair of poles in the generator would have this effect. Many generators are multipolar, some of them with as many as 36 poles, to reduce the speed necessary for a given output. Addition of poles must be by pairs, with consideration of weight and space as the only limiting factor.

3. DC GENERATORS

The distinguishing structural characteristic of a DC generator is the commutator. The

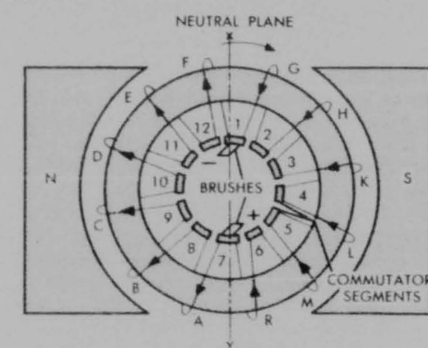

Figure 5—35. Commutators in DC Generator.

EMF and current in the armature coils of a DC machine are alternating the same as in an AC machine. It is by means of the commutator that the alternating EMF and current of the coils are collected as direct current for the external circuit.

The commutator consists of a number of wedge-shaped copper segments fitted together. The segments are insulated from each other by thin sheets of mica and the whole assembly is insulated from the shaft. A glance at the construction of the commutator reveals that mechanically it is the weakest part of the machine. Most of the electrical troubles originate at the commutator and brushes. The weakness of the commutator places a definite limit upon the safe speed of the rotation of the armature.

The two ends of each coil of the armature winding are mortised into, and soldered to adjacent commutator segments. Each commutator segment carries one terminal of each of two adjacent coils, one being the forward end of one coil and the other the rear end of the adjacent coil. Since each coil has two terminals and each commutator segment makes contact with two coils terminals, there must be as many commutator segments as there are coils. The illustration in Figure 5-35 will serve to make the statements clear. It is a schematic representation of a DC machine. For the sake of clarity in illustration, the coils have been shown as consisting of a single loop instead of the many turns of a full coil.

It is evident, upon examination of Figure 5-35 that the application of the left-hand rule shows the EMFs in the coils to be in a direction as indicated by the arrows. In both sides of the armature windings the EMFs induced in the coils are in a direction toward segment 1 and away from segment 7. Thus the two sides of the armature are in parallel, giving two paths for the current flow. The EMFs induced in the coils A, B, C, D, E, and F, being in the same direction and in series, are additive; and the total voltage of the generator is the sum of the voltages induced in the coils. The other six coils form a similar circuit and have a similar voltage, but being parallel the two voltages do not add, but act the same as cells in parallel. Therefore the voltage of a generator is the sum of the voltages in the coils in any one parallel path.

If the brushes are set upon segments 1 and 7, in the vertical plane represented by the dashed line, the upper brush will collect the current from the coils and is the positive terminal for the external circuit. The lower brush is the negative terminal, receiving current from the external circuit. That vertical plane (a plane perpendicular to the lines of force) which is midway between the poles is termed the neutral plane; for, when the coil passes through this plane, no EMF is induced. The neutral plane, then, is that plane in which no EMF is produced when cut by a conductor. The brushes in Figure 5-35, therefore, are set in the neutral plane, X and Y.

When a generator is delivering current to an external circuit, the current flow through the coils of the armature produces a magnetic field produced by the field coils. This effect is called the armature reaction of the generator. The neutral plane in Figure 5-35 was found to be also the vertical plane. This is true only when no current is flowing through the armature coils of a generator. As soon as current flows in the armature, the effect of armature reaction is to shift the neutral plane forward in the direction of rotation. This is one reason for the generator brushes not being actually set in the vertical plane as shown in Figure 5-35 but being set at some angle to the vertical.

The brushes of a DC generator are not set in the vertical plane, or in the shifted neutral plane. Instead, they are set just beyond the shifted neutral plane to prevent sparking between the brushes and the commutator. The armature coils are essentially highly inductive. Sparking in an inductive circuit occurs whenever current is flowing in the circuit and the circuit is broken. Before coil F, see Figure 5-35, reached the shifted neutral plane it is under the influence of the north pole and the direction of the current is as shown by the arrowhead. When commutator segment 1 and the commutator segment 12 are both in contact with the brush, coil F is short-circuited; a relatively heavy current flows through the circuit consisting of coil F, the two commutator segments 1 and 12, and the brush, until just after coil F passes through the shifted neutral plane. The size of this short-circuit current is reduced to a minimum in a DC generator by the use of carbon brushes, which have a higher resistance than metallic brushes. When commutator segment 1 leaves the brush, this short-circuit will be broken, and unless the current in coil F has been reduced to zero, a heavy sparking will occur at the trailing end of the brush. Therefore, the brushes are shifted so that commutator segment 1 leaves the brush just after coil F has come under the influence of the south pole of the generator. At this position, the current in coil F is reduced to zero because of the combined action of the self-inductance of the coil and the action of the south pole upon it, and sparking is at a minimum. In a 4-pole generator there are four positions in which a coil cuts no lines of force; hence, such a generator has two neutral planes at right angles to each other. Since two brushes are required for each neutral plane, the 4-pole generator has four brushes, two of which are positive and two of which are negative. The two positive brushes are strapped together as the two negative brushes are. There are four paths through the armature and the EMF of the generator is the sum of the EMFs in one-fourth of the windings.

It can be seen that although the EMF supplied to the external circuit is always in the same direction, it varies slightly in value from instant to instant, since the coil cuts the lines

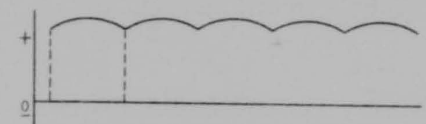

Figure 5—36. DC Generator Output.

of force at varying angles as it rotates through the field. This slight variation in value of the EMF taken from a DC generator is called ripple. The more coils in the winding of the armature, the smaller will be the ripple, as the number of lines cut by the increased number of coils will remain more constant. The EMF furnished to the external circuit by the generator of Figure 5-35 would have a waveform as shown in Figure 5-36.

DC generators are normally self-excited; that is, the current for the windings of the field magnets is taken from the commutator of the generator. This is possible because of the residual magnetism remaining in the cores of the electromagnets. When the machine is started, the armature starts turning in a weak field produced by the small amount of residual magnetism retained. The armature, in cutting this weak field, induces an EMF in the coils of the armature, and this induced EMF drives a current through the field coils which are connected in series or in parallel with the armature. The current increases the strength of the field magnets, thereby increasing the EMF induced in the armature coils, causing more current to flow through the field coil, again increasing the field strength, etc. It would appear that the EMF of the machine would continue indefinitely, building itself up to greater and greater values, but such is not the case. The maximum EMF of the machine is limited by the resistance of the field windings and the magnetization characteristics of the field magnets (saturation point).

Occasionally a DC generator that has the field coils reconnected will not build up its voltage. It may be that the residual magnetism is opposing the field from the field current. To remedy this condition, reverse the field connections.

4. TYPES OF DC GENERATORS

DC generators are generally known as shunt-series, or compound-wound generators. This designates the different types of generators in relation to the construction of their field windings. See Figure 5-37.

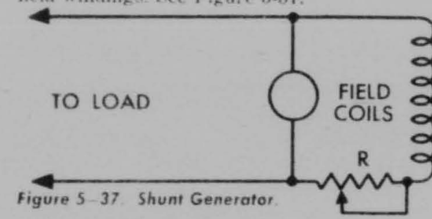

Figure 5—37. Shunt Generator.

The Shunt Generator

The shunt generator is so called because its field winding is connected in parallel (shunt) with the external circuit.

A schematic diagram of a shunt generator is shown in Figure 5-37. The field coils of a shunt generator are composed of many turns of small wire, and the magnetic strength is derived from the number of turns, rather than the current strength through the coils.

The shunt generator is suitable only for circuits requiring a steady flow of current at a steady voltage. It is not suitable for rapidly fluctuating loads if a constant voltage is required. Any increase in the current in the external circuit will cause an increase in the armature current. As the armature current increases, the IR drop through the armature is increased. The voltage delivered at the terminals is the difference between the induced voltage and the voltage drop. Thus, as the IR drop increases, the delivered voltage decreases. This decrease in voltage causes a decrease in the field strength, as the current through the field coils decreases in proportion to the decrease in terminal voltage; and with a weaker field, the voltage is further decreased, until a balance is reached.

Shunt generators are suitable for battery charging in a central office, and for similar application where the current drain is fairly steady. The voltage of a shunt generator may be controlled where necessary by the use of a rheostat in series with the shunt field.

THIS PAGE IS DECLASSIFIED IAW EO 13526

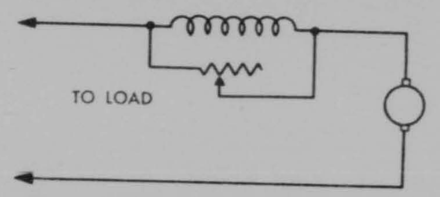

Figure 5–38. Series Generator.

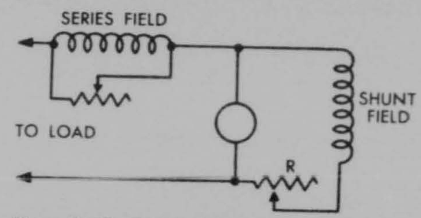

Figure 5–39. Compound Generator.

The Series Generator

The series generator, like the shunt generator, gets its name from the method used in connecting the field coils.

Figure 5-38 shows a schematic diagram of a series generator. The field coils of a series generator are composed of a few turns of large wire, and the magnetic field strength is derived from the current flow rather than the number of turns in the coils. The wire must be large since all of the current for the external circuit must pass through the coils.

Series generators have very poor voltage regulation under changing load; the greater the current through the field coils to the load, the greater will be the induced EMF and the increase in the terminal voltage of the generator. Therefore, when the load is increased the voltage will also increase. Because the series-wound generator has such poor regulation, it is seldom employed solely as a series machine; the series winding is used in other types of combination machine. The voltage of the series generator can, however, be controlled by a rheostat in parallel with the field coil.

The Compound-wound Generator

This generator is a combination of the shunt and series windings, and gets its name from this fact. The two separate windings are illustrated in Figure 5-39.

If the terminal voltage remains constant in a compound-wound generator, the ampere-turns of the shunt field are constant, but the ampere-turns of the series field vary directly with the current passing through them to the external circuit. Thus, the field strength increases and the EMF of the generator increases with an increasing load. If the series field contains the proper number of turns, the EMF of the generator may be made to rise sufficiently to compensate for the increasing drop of the potential in the armature IR drop. When the turns in the series field are just enough to keep the terminal voltage of the machine constant, the generator is said to be flat compounded. When the terminal voltage rises with an increase in load, the generator is over-compounded, and if the terminal voltage decreases with an increase in load, the generator is undercompounded.

In battery charging, it is often desired to change the rate of charge; therefore, some means must be designed to control the output of the generator. This is accomplished by placing a rheostat in series with the shunt field and a rheostat in parallel with the series field (see Figure 5-40). By a study of the circuit, it is noted that if rheostat 1 is varied, the current through the shunt field will vary, thus decreasing or increasing the voltage output of the generator. The same is true of rheostat 2, except that it controls the current through the series field by shunting a portion around the coils.

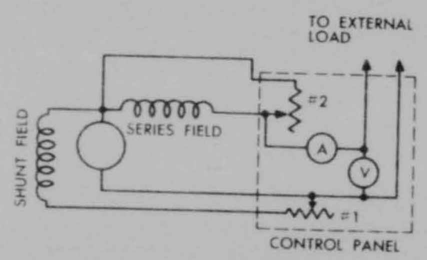

Figure 5–40. Generator Voltage Control.

SECTION VII—SHUNT, SERIES, AND COMPOUND MOTORS

1. MOTOR PRINCIPLES

Motors, like generators, are simply a means of transforming energy or power. Motors convert electrical power into mechanical power. The essential features and parts of all motors and generators are the same, and all DC motors may be used as generators. The DC motor has field coils, armature coils, and a commutator with brushes, the same as the essential parts of a generator.

To understand the torque (or turning effect) that is developed by a motor, an analysis should be made of a single-loop armature, mounted between the pole pieces of a permanent magnet. A cross-section of the conductors of such an armature is shown in Figure 5-41.

The field produced by a permanent magnet, in the absence of any disturbing force, travels the shortest route, which is directly across the conductors from the north pole to the south pole. If current is sent through the conductors of the loop, a field is set up around each conductor in a direction as determined by the left hand rule. These fields, due to current flow in the conductors, distort the main field and cause a piling-up, or flux pressure, on one side of each conductor and a flux vacuum on the other side. This causes a force to act upon the conductors which tends to push them into the vacuum, and to straighten out the distorted lines of force. If the field lines of force are thought of as rubber bands, and the conductors as some object pressing upon them, the effect upon the conductor may be understood more clearly. See Figure 5-42.

To determine the direction of rotation of a motor, the right hand is used, the method being known as the right-hand rule. This rule is similar to the left-hand rule for generators, except that the right hand is now used.

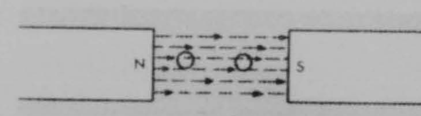

Figure 5–41. Conductors in a Magnetic Field.

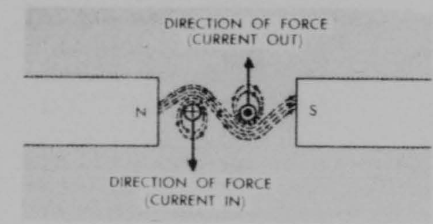

Figure 5–42. Motor Action.

2. SHUNT MOTOR

The shunt motor is structurally the same as the shunt generator and its schematic diagram is drawn in the same manner.

Since the field coils are always connected directly across the power supply, the current through the field will be constant. Therefore, the magnetic field will be constant and the torque of the shunt motor will vary only with the current through the armature. (The amount of torque depends upon the relative coupling between the fields set up by the armature coils and the field coils. The greater this coupling, the greater the torque.) With the armature coils rotating in a magnetic field, there is also an EMF induced. Thus, there is motor and generator action at the same time. This EMF induced will be in such a direction as to oppose the applied EMF, therefore it is a CEMF.

The amount of current which flows through the armature will depend upon the resistance of the armature and the difference between the applied voltage and the CEMF. The CEMF depends upon the speed with which the flux lines are cut, and since the armature coils are fixed to the armature core and the field does not vary, the CEMF depends solely upon the armature speed. The following formula is used for motor calculations:

$$\text{Armature current} = \frac{\text{E applied} - \text{CEMF}}{\text{RA}}$$

where R_A = armature resistance.

For example, suppose a motor develops a CEMF of 100 volts at 1,000 rpm, the armature resistance is 1 ohm and the applied voltage is 105 volts. Find the armature current at 1,000 rpm and 900 rpm.

CEMF = 100 volts at 1,000 rpm
RA = 1 ohm
E APPLIED = 105 volts

$$I_A = \frac{105 - 100}{1} = 5 \text{ amps at } 1{,}000 \text{ rpm.}$$

At 900 rpm, the lines cut will be 900 ÷ 1000 or 9/10 of the lines cut at 1,000 rpm, thus the CEMF will also be only 9/10 of that for 1,000 rpm, or 100 × 9 ÷ 10 equals 90 volts CEMF developed at 900 rpm. The current then would be:

$$IA = \frac{105 - 90}{1} = 15 \text{ amps at 900 rpm}$$

Since the CEMF developed is proportional to the speed of a motor, if a motor were at a standstill, and a voltage were applied to the motor terminals, there would be no CEMF to oppose this voltage, as the armature would not be cutting lines of force. Therefore, the current through the armature in the preceding example would be 105 amps, and this high surge of current occurs only on starting, and drops off as motor gains speed.

The speed of a shunt motor is fairly constant under changing load. As the load is applied, the speed of the armature rotation decreases, thus decreasing the CEMF and increasing the current. This increase in current boosts the coupling between field and armature and hence increases the torque, causing the motor again to resume approximate running speed.

The speed of a shunt motor may be controlled by a rheostat in series with the armature, or a rheostat in series with the field winding, or both; the rheostat in series with the field is the most common method. Adding resistance in series with the armature reduces the armature current, consequently lessening the torque and causing the motor to slow down until the current increases sufficiently to give the required torque. Adding resistance in series with the field winding reduces the field strength, decreasing the CEMF, thereby permitting more current to flow in the armature. The increased current speeds the motor due to the increased torque until the increasing CEMF reduces the current a sufficient amount to give the required torque. A rheostat in series with the field winding is preferable to a rheostat in series with the armature, because the field current is much smaller than the armature current and the power loss in the field rheostat will be much less than the power loss in an armature rheostat.

As the current flow through a motor armature is opposite to the current through a generator armature, the armature reaction tends to shift the neutral plane back of the vertical plane rather than forward as it did in the case of generators. Therefore, the brushes of a shunt motor are set back of the neutral plane instead of forward.

The shunt motor will operate only on direct current. The field and armature windings of this motor are in parallel, and the reactances of the two circuits when using alternating current are very different. This difference of reactance is due to the structural design of the two circuits. If alternating current were impressed across the shunt motor, the difference in reactance would cause the field current and the armature current to be out of phase and continuously changing phase. The operation of the motor would be unpredictable and the motor would be of little practical use.

3. SERIES MOTOR

The series motor may be operated on either alternating current or direct current, since the field is of low impedance and the same current flows through both the armature and the field. There can be no difference of phase between the field and armature in the series motor as in the shunt motor, because the field and armature current change direction together. If the motor is operated on direct current, the brushes are set back of the neutral plane to compensate for the armature reac-

tion. If the motor is operated on alternating current, the brushes are set in the vertical plane. The field cores must be laminated, if alternating current is used, to cut down the loss due to eddy currents.

The series motor is adapted for giving a very high starting torque. The torque of a series motor varies approximately as the square of the current. If the armature current is doubled, the flux is also doubled, since the same current passes through the field coils. Hence the torque, proportional to current x (flux) is increased four times. When the armature is at rest, the armature current (and therefore the torque) is at a maximum, because there is no CEMF generated in the coils and the current is equal to the impressed voltage divided by the resistance of the armature coils and the field coils. As the armature gains speed, the CEMF increases, thus decreasing the armature current and torque. If load is added to the armature, the armature slows down, decreasing the generated CEMF, allowing a greater current to flow, thus producing a greater torque. The speed of the series motor is controlled by the load, and if the load is removed, the motor will race dangerously. Series motors are therefore generally used only where the load is constantly applied and a good starting torque is required. Series motors are used in hoists, street cars, etc.

4. COMPOUND MOTOR

The compound motor, like the compound generator, has a combination of the series and shunt windings, and combines the separate characteristics of each. By making the field strength of one winding more powerful than that of the other winding, a compound-wound motor may be made to have the approximate characteristic of either a shunt or a series motor.

There are two types of compound windings: the cumulative compound, and the differential compound.

The Cumulative Compound

In the cumulative compound, the coils are wound upon the core in the same direction so that the magnetic fields tend to aid each other; from this fact comes the name cumulative-compound motor. A motor thus connected will have a very good starting torque, but poor speed regulation. Motors of this type are used for machinery where speed regulation is not necessary but where great torque is desired to overcome sudden application of heavy loads.

The Differential-compound Motor

The differential-compound motor has its windings wound in opposite direction so that the series-field winding oppose the shunt-field winding. A motor of this type may be made to operate at almost constant speed under varying load. As the load increases and the motor tends to slow down, the current in the series-field winding increases because of the decrease in CEMF.

The shunt-field winding draws a constant current as it is connected directly across the line. Since the series winding opposes the shunt winding, this increase in current through the series field will reduce the strength of the combined field. A decrease in the combined field will cause the motor to speed. If the number of turns on the series winding is properly chosen, the combined effects of the increased load and weakened resultant field neutralize each other and the speed will remain constant.

5. SUMMARY OF CHARACTERISTICS

The characteristics of motors may be classified as follows:

Shunt

A shunt motor has constant speed, fairly good speed regulation, speed control through variation of field resistance, good starting torque, and a tendency to run away if the field is open and it operates on direct current only.

Series

A series motor has speed dependent entirely upon the load, and a very high starting torque. The speed is controlled by variations of the field resistance, and it operates on either alternating current or direct current.

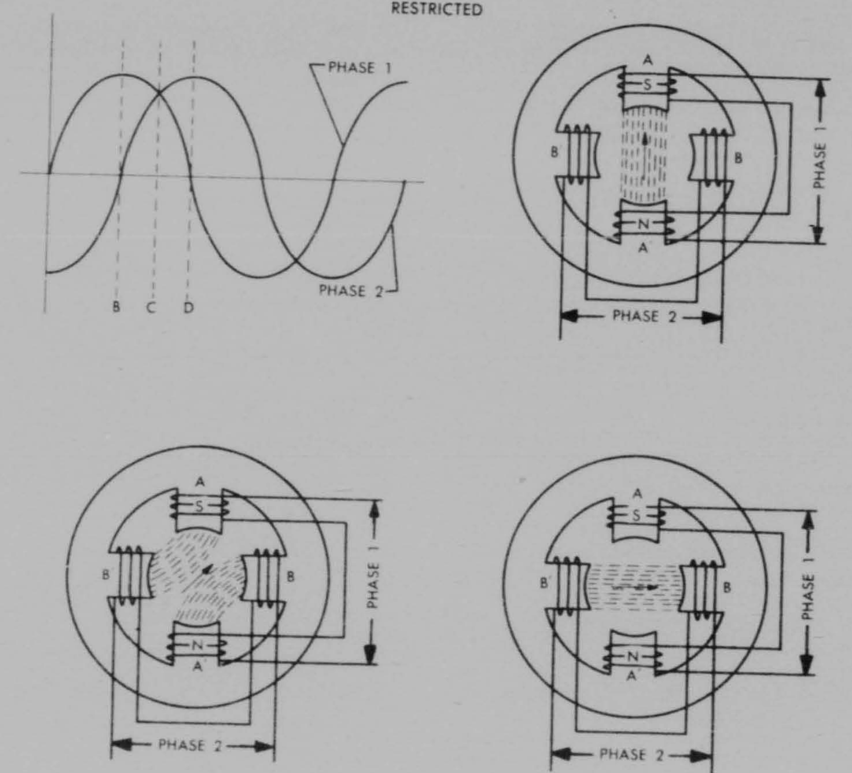

Figure 5–43. Production of Rotating Field.

Compound

A compound motor has speed which may be uniform throughout a wide range of load, speed control through variation of the field resistance, and good torque.

6. INDUCTION, SYNCHRONOUS, AND REPULSION MOTORS

The motors studied thus far were primarily DC motors, although with modifications in design, certain of them, notably the series motors, may be adapted to use on alternating current. The induction and repulsion motors now being covered are operated exclusively on alternating current.

Note: Thus far the discussion of alternating current has been limited to single phase alternating current, since this is the simplest method by which the student can acquire a conception of the AC principles and the quantities encountered in AC circuits. However, when AC power in large amounts is required, the general practice is to use multiphase alternating current, that is, more than one phase. Two-phase and three-phase systems are most common. It is possible to construct AC generators which will produce more than one EMF wave simultaneously, and at the same time maintain a constant phase relationship among them. In a two-phase system, for example, the phase angle between the two EMFs is 90 degrees, while in a three-phase system the angle is 120 degrees. Another way of stating the same facts is to say that in a two-phase system the two EMFs reach their maximum

values 90 degrees apart, while in a three-phase system, they reach their maximum values 120 degrees apart. The explanation of multiphase AC operation which follows is intended for purposes of reference only.

Principles of Multi-phase AC Motors

Multiphase AC motors depend for their operation upon the principle of a rotating magnetic field. As a simple illustration of the principles of a rotating magnetic field imagine a horseshoe magnet held over a compass needle. The needle will immediately take up a position parallel with the magnetic flux passing from one pole of the magnet to the other. If the magnet is rotated the compass needle will follow.

A rotating magnetic field can be produced by multiphase currents flowing through two or more groups of coils wound on inwardly projecting poles of an iron yoke. The coils on each group of poles are wound alternately in opposite directions to produce opposite polarity, and each group is connected to a separate phase of a multiphase EMF. This action will be explained with the aid of Figure 5-44, which shows a 4-pole field stator energized by two windings connected separately to the two phases of a two-phase generator. The direction of the magnetic field will be indicated by a magnetic needle (considered as a north pole only for convenience) which will always move to a position where it will be parallel with the magnetic flux passing from pole to pole and attracted to the resulting south pole.

Figure 5-43 illustrates the phase relationship of the two EMFs which are applied to the two windings of the field, phase 1 supplying current to the coils on poles A and A', and phase 2 supplying current to the coils on poles B and B'. The two EMFs are 90° out of phase with phase 1 leading. (1) At instant b (Figure 5-43), the current of phase 1 is at a maximum. The poles of coils A and A' are fully magnetized while the poles of coils B and B' are not magnetized, since the current in phase 2 is zero at this instant. Consequently, the magnetic needle will assume the position shown. (2) At instant c (Figure 5-43), the current in the coils A and A', phase 1, has decreased to the same value as that to which the current in coils B and B', phase 2, has increased. The four poles are now equally magnetized, concentrating the strength of the field midway between the poles and causing the needle to take the position shown. (3) The next instant, d (Figure 5-43), the current of phase 1 is zero and coils A and A' have no magnetism, while the current through coils B and B' is at a maximum; hence, the field strength is at a maximum and the needle is now in a horizontal position. (4) The above action is repeated during successive instants of the flow of the alternating currents, and the needle continues to revolve in the same direction within the field frame as long as the two-phase currents are supplied to the two sets of coils. If the compass needle is replaced by an iron core wound with copper conductors, secondary currents will be induced in these conductors producing a magnetic field which will react on the rotating magnetic field and cause rotation of the iron core. The direction of rotation may be reversed by changing the connections of one of the phases.

Induction Motor

The multiphase induction motor, has two elements; the fixed element or stator, and the movable element or rotor. However, the rotor of the induction motor is not energized from an external source. Briefly, the operation is as follows: A multiphase AC source of EMF is applied to the stator windings, producing a rotating magnetic field of force which cuts the conductors of the rotor, thereby inducing an EMF in them. The conductors form a closed circuit and the induced EMF therefore causes a flow of current. The interaction between this current and the air-gap flux causes the rotor to turn.

The speed of the induction motor is always less than the speed of the rotating field of the stator. If the rotor were to turn at the same speed as the rotating field, the rotor conductors would not be cut by any magnetic lines of force; no EMF would be induced in them, no current could flow, and with no current flow there could be no interaction with the air-gap flux and hence no torque.

A multiphase induction motor exerts a torque when at rest; therefore, it will start

THIS PAGE IS DECLASSIFIED IAW EO 13526

itself when the proper EMF is impressed on the stator. Small induction motors may be connected directly across the source of EMF. Starting compensators or some other means of reducing the starting current to a reasonable value are generally used with large-sized induction motors.

In addition to the multiphase induction motors just described, there are also single-phase induction motors. These machines have no rotating magnetic field and therefore no starting torque. Starting is accomplished, generally, by either one of two means: as a repulsion-start induction motor, in which case the machine starts as a repulsion motor and upon reaching a certain predetermined speed functions as an induction motor; or, as a split-phase induction motor in which case there are actually two windings, one of greater reactance than the other. The fields of these two windings will be sufficiently out of phase so that the resultant field will approximate a rotating field and produce a starting torque. When the motor has attained a certain speed, the second winding is disconnected and the machine will function as a single-phase induction motor.

The induction motor may be adopted to a greater variety of uses than any other type of AC motor. Its operating characteristics are good, it is simple and rugged in construction, and it requires a minimum of maintenance.

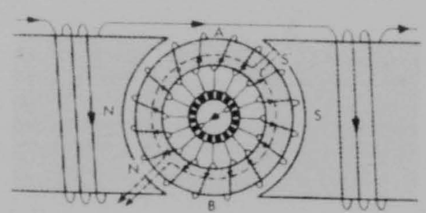

Figure 5-44 AC Repulsion Motor

Repulsion Motor

The repulsion motor, in its construction, may be thought of as a combination of an AC and a DC motor. Its stator is similar to that of a single-phase induction motor and its rotor like that of a DC motor. It is provided with brushes which are short-circuited. The operation of the repulsion motor may be described with the aid of Figure 5-44.

The magnetic field of the stator is assumed to be increasing in the direction shown. This field induces an EMF in the armature conductors and causes a current to be set up in the direction shown by the arrowheads. By placing the brushes at the angle shown, the current in the armature conductors will produce a magnetic field about the armature which will have definite N and S poles. These poles are repelled by the poles of the stator field, causing the motor to rotate in a counterclockwise direction. It is also from this fact that the motor derives its name.

The repulsion motor principle finds its greatest application when used to provide starting torque for single-phase induction motors.

7. SUMMARY OF MOTOR CHARACTERISTICS

The characteristics of the various types of AC motors described in the present lesson may be summarized as follows:

Induction Motor

The induction motor has reasonably constant speed, simple and rugged construction, and a wide variety of sizes. It requires a minimum of maintenance. The multiphase motor has good starting torque; the single-phase motor requires special measures for starting.

Repulsion Motor

The repulsion motor has good starting torque, and its principal application is in the starting of single-phase induction motors.

8. MAINTENANCE

The care and maintenance of motors and generators is a subject which cannot be emphasized too strongly. Any piece of moving machinery in order to function as its designer intended, must receive the proper care and treatment peculiar to that particular machine. However, it is not within the scope of this section to include anything more than a brief discussion of the general precautions

which should be observed for the proper operation of motors and generators. Specific instructions are generally published by the manufacturer or may be obtained from training manuals.

Bearings

The bearings of the machine should be lubricated with the proper grade of oil. The frequency of lubrication will depend upon the particular machine in question and the size of the oil reservoir associated with each bearing.

Commutator

The surface of the commutator should always present a bright, clean appearance. A clean, lint-free cloth should be used to maintain this condition. The commutator should never be oiled, although a small amount of vaseline may be applied after cleaning. The surface of a commutator may become rough and when this occurs, steps should be taken to restore the original condition. Minor surface irregularities may be removed with a piece of sandpaper, backed with a wooden block, held against the commutator. Emery or emery cloth should never be used. If the surface irregularities are of a more severe nature, the armature should be removed and the commutator turned down with a lathe. A common cause of surface irregularities is high mica, a condition resulting from the copper segments wearing away at a faster rate than the mica insulation between them.

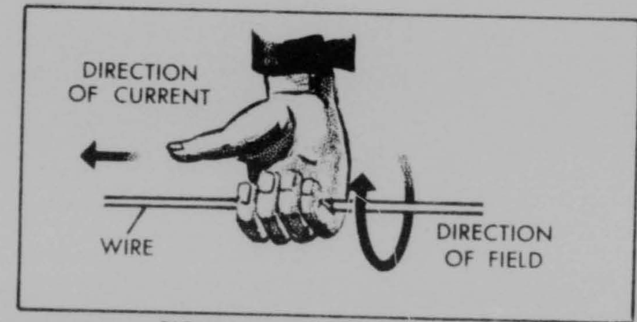
Brushes

Brush tension should be such that they make firm, but not tight contact with the commutator, and do not chatter or heat unduly. Excessive sparking at the brushes is undesirable and frequently is the result of incorrect brush position. In addition to incorrect brush position, sparking may be due to overload, rough or dirty commutator, high mica, improper brush tension, short circuited or grounded armature coil, or weak field excitation. The remedial measures to be applied are obvious.

Trouble Indicators

The temperature of a motor or generator provides a very accurate indication of whether or not the machine is operating properly. High temperatures indicate trouble. A good rule-of-thumb is that a temperature which cannot be borne by the hand is too high for safety.

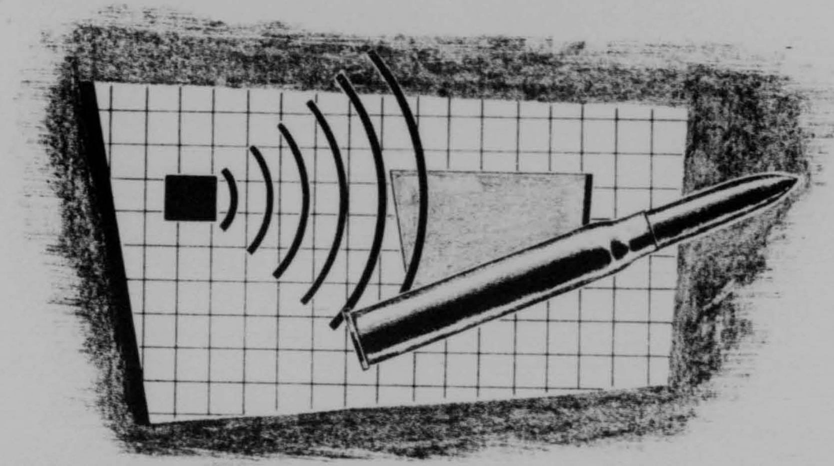
The sound of a motor or generator, next to the temperature, is the best trouble indicator. When operating properly it should hum steadily. If it is overloaded it will "grunt." A knocking sound generally indicates a loose armature coil, the shaft out of alignment, or the armature striking a pole piece.



RIGHT-HAND THUMB RULE

THIS PAGE IS DECLASSIFIED IAW EO 13526

CHAPTER 6—EXPLOSIVES, AMMUNITION AND BALLISTICS



SECTION I—EXPLOSIVES

1. MILITARY EXPLOSIVES

General

To understand the composition and functioning of a complete round of ammunition, a basic knowledge of the characteristics and uses of military explosives is necessary. In order that ammunition may function at any time and place desired, it is necessary to employ different kinds of explosives, each having a specific role. Explosives suitable for one purpose may be entirely unsatisfactory for another. Thus, the explosive used to burst a forged steel projectile would not only be unsuited but also highly dangerous if used to propel the projectile out of the weapon. Similarly, the explosives used in initiators, such as in primers and fuses, are so sensitive to shock that only small quantities can be used safely.

Definition

Any mixture or compound which, under the influence of heat or mechanical action, undergoes a sudden chemical change (decomposition) with the liberation of heat and light energy accompanied by a large volume of gases, is called an explosive.

Classification

Explosives are classified as low and high explosives according to their rates of decomposition when such decomposition is initiated by the spit of a flame or mechanical shock. Therefore, explosives are divided into two basic groups: low explosives (propellants) and high explosives.

Low Explosives. Low explosives are combustible materials which decompose very rapidly; this action is called deflagration. In decomposition, they produce a large volume of gases which, in turn, produce enough pressure to propel a projectile or rocket forward. The rate of burning is important and depends upon such factors as pressure, grain form,

THIS PAGE IS DECLASSIFIED IAW EO 13526

composition, etc. Low explosives do not usually propagate a detonation. Under certain conditions, however, they react in the same manner as high explosives, that is, they may detonate.

High Explosives. High explosives are characterized by the extreme rapidity with which the decomposition occurs; this action is called detonation. They decompose almost instantaneously, either in a manner similar to an extremely rapid combustion, or with rupture and rearrangement of the molecules themselves. The disruptive effect of the reaction makes the explosive valuable as a bursting charge. However, it precludes its use as a propellant because the gases are formed so quickly that excessive pressures would be developed which might burst the barrel of the weapon. A detonation may be pictured as resulting from an explosion wave traveling through the high-explosive charge at an extremely high velocity.

Requirements of an Explosive

When the entire field of explosives is considered, the term "military high explosives" has a restricted application to a relatively small number of substances. Before an explosive can be adopted for military use, careful consideration must be given to its various properties and characteristics. The chief characteristics to be considered are stability, brisance, sensitivity, economy of manufacture and the explosive susceptibility to complete ignition or detonation.

Specific Military Requirements

If an explosive is to meet military requirements all the aforementioned characteristics must come up to specified standards.

Stability. Stability refers to the capacity of an explosive to retain unaltered its chemical and physical properties during an indefinite period of storage under normal conditions or at higher than normal temperatures. It also embraces the explosive's ability to withstand the mechanical shocks incident to loading, transportation and handling; its ability to withstand the shock of set-back on the firing weapon (when used in artillery shell), or impact when dropped "safe" (when used in bombs).

Sensitivity to shock or impact. Sensitivity to shock or impact refers to the ease with which an explosive can be detonated by the sudden application of mechanical force.

Sensitivity to detonation by means of initiators. The standard sensitivity to detonation by initiating agents other than mechanical impact is expressed in terms of the amount of initiating explosive; for example, the amount of mercury fulminate required to effect complete detonation of a given weight of explosive under a given set of conditions.

Brisance. Brisance is the ability of a detonating explosive to shatter material close to it. This property is different from the potential heat energy of the explosive, sometimes referred to as power or strength, which determines the force an explosive can exert when it explodes. Such force depends upon the amount of gas generated and the temperature reached during an explosion. Brisance, on the other hand, depends on the velocity with which a detonation occurs. Black powder, for instance, is a "powerful" explosive because of the large amount of gas it generates upon explosion. Its brisance, however, is very low because of the low rate of explosion.

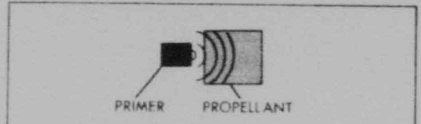


Figure 6–1. Simple Explosive Train.

2. EXPLOSIVE TRAINS

General

The arrangement of a series of explosives beginning with a small quantity of sensitive explosive and terminating with a relatively large quantity of comparatively insensitive explosive is termed an "explosive train." In general there are two such trains—the propelling-charge explosive train (which is always a low-explosive train), and the bursting-charge explosive train (which may be either a high or low-explosive train). In all explosive ammunition one or both of these explosive trains will be found.

Small-arms Ammunition. In small-arms

cartridges where the propelling charge is relatively small, the components in this train are a percussion primer and a propelling charge. The firing pin explodes the primer and the flame passes through the vent leading to the powder chamber and ignites the propelling charge. The expansion of the resultant gases forces the bullet out through the bore of the weapon.

Bursting-charge Explosive Trains. Although there are two explosive trains—the propelling-charge explosive train and the bursting-charge explosive train, the term "explosive train" as commonly used is intended to mean the bursting-charge explosive train. Bursting-charge explosive trains may be classified as high-explosive trains or low-explosive trains.

Low-explosive Train. When low-explosive projectiles or other types of missiles reach the point of functioning, the series of explosions which takes place is known as the low-explosive train. In base-ejection smoke shells, the explosive train consists of a percussion primer, a time train of black powder, a magazine charge of black powder, and an expelling charge of black powder. The action is initiated by the firing pin of the fuse striking the primer, the resultant flame being transmitted through the component next to the expelling charge. The explosion of the expelling charge forces the smoke canisters out of the base of the projectile.

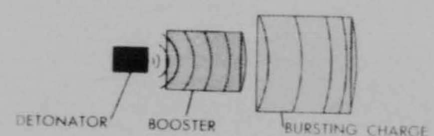

Figure 6–2. High-Explosive Train.

High-explosive Train. When the bomb reaches the target or the point at which it is set to function, the series of explosions which take place in order to detonate the bomb is known as the high-explosive train. The basic components which must be present in practically all high-explosive trains are a detonator, a booster, and a bursting charge. Other elements are sometimes required, but these three charges are fundamental.

The detonator sets up a high-explosive wave when initiated by the stab action of a firing pin or by a flame. This detonation is so small and weak that it will not initiate a high-order detonation in the bursting charge unless a booster is placed between the two. The booster picks up the small-explosive wave from the detonator and amplifies it to such an extent that the bursting charge is initiated with a high-order detonation.

To gain the action necessary to control the time and place at which an explosive will function, it is necessary to incorporate other components in the high-explosive train. The action desired may be a burst in the air, a burst instantly upon impact with the target, or a burst shortly after the bomb has penetrated the target. The components which may be used to give these various actions are a primer, a black-powder delay pellet or train, an upper detonator, or any combination of these components.

The action which causes a bomb to burst in the air may be obtained by placing a clockwork type device in the fuse to release the firing pin that initiates the explosive train a given number of seconds after the bomb leaves the aircraft.

To burst the bomb promptly upon impact with the target, a superquick or instantaneous action is necessary. This action is usually obtained by placing an upper detonator in the extreme front of the fuse and a lower detonator in the body near the booster charge. In this manner, the detonating wave is transmitted instantly to the bursting charge.

To permit penetration of the target by the bomb, a delay action is necessary. This is obtained by placing a primer and delay element ahead of the detonator.

A variation of the high-explosive train is found in the chemical shell. In this train there is no large bursting charge such as is found in a high-explosive bomb, as it is only necessary to rupture the bomb case and allow the chemical contents to escape. The actual bursting of the case is accomplished by an enlarged booster, known as a burster charge contained in a tube running down the center of the bomb.

3. PROPELLANTS

General

All explosives currently used as propellants have a nitrocellulose base and are commonly known as smokeless powders. Various organic and inorganic substances are added to the nitrocellulose base during manufacture to give improved qualities for special purposes. These powders are distinguished by such terms as double-base, flashless, and smokeless, as well as by commercial trade names or symbols. Black powder, which was formerly classed as a propellant, is no longer used as such but is now used as a delay element, as an igniting charge for propellants, in flash reducers, or for other special purposes.

Smokeless Powder

Characteristics. Smokeless powder is essentially gelatinized nitrocellulose and is manufactured in the form of flakes, strips, pellets, or perforated cylindrical grains. Powder is made in different shapes to obtain certain types of burning. The cylindrical grains are made in various diameters and lengths. Grains vary in diameter from 0.032 inch for cal. 30 cartridges to 0.947 inch for 16-inch propelling charges; they also vary in corresponding lengths from 0.085 inch to 2.170 inches. For small-size grains either no perforation or a single perforation is required. However, for larger grains, seven equally-spaced perforations are present in order to have a large-burning surface area. The critical dimension is the web size, that is, the average thickness of the powder between the perforations. In color, the grains vary from a light amber to a deep brown or black.

Solvent. Smokeless powder is manufactured to contain in the finished grains a definite amount of solvent (an ether and alcohol mixture). This amount varies from 0.5 to 5 per cent. If there is a marked change in the amount of solvent, a change in ballistic properties will result. Powder must be carefully protected against high temperatures and moisture. To guard against changes due to such conditions, smokeless powder is always packed in airtight containers. Some rocket propellent powder may not contain any solvent.

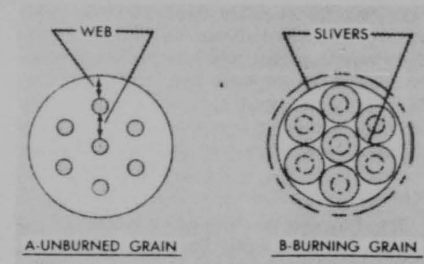

Figure 6–3. Progressive Burning of Powder Grains.

Burning Action

General. Unconfirmed smokeless powder burns with little ash or smoke but, when confined, its rate of burning increases with temperature and pressure. In order not to exceed the permissible chamber pressure of the weapon in which it is to be used, the rate of burning of the propellent has to be controlled. At constant pressure, the rate of burning is proportional to the powder surface free to burn. Therefore, powder is made into accurate sizes and definite shapes. Figure 6-3 illustrates the "progressive" burning of a powder grain.

Degressive Burning. As the surface of the cord and strip forms of smokeless powder change with burning, the surface of the grain decreases. The burning action of these grains is, therefore, classified as "degressive."

Neutral Burning. As a single-perforated grain burns, the outer surface decreases and the inner surface increases. The result of the two actions is that the total surface remains approximately the same in area. The burning of this type of grain is known as "neutral."

Progressive Burning. When the multiperforated grain burns, the total surface area increases since the perforated grain burns from the inside and outside at the same time. This type of burning is called "progressive" (Figure 6-3).

Slivers. When a multiperforated grain is not completely consumed, portions of the grain remain in the form of slivers B (Figure 6-3) and are normally ejected as such from the weapon.

Use. Nitrocellulose smokeless propellants are used as the propellant for small-arms and larger-caliber ammunition. The perforated form of grain is the one most commonly used in United States military powders. Single perforated grains are used for small-arms, minor-caliber weapons, and certain howitzers. Powders with seven perforations are used for larger-caliber weapons.

Double-base Powder (Ballistite)

Ballistite is a combination of nitroglycerin and nitrocellulose, containing approximately 13.15 to 13.25 per cent nitrogen obtained by mixing pyro powder (12.6 per cent nitrogen) with guncotton (13.35 to 13.4 per cent nitrogen). The nitroglycerin serves to increase the potential. Small percentages of inorganic salts are often added to reduce the flash and increase the ease of ignition. Ballistite is used in shotgun shells, field mortar increments, and rocket motors. Double-base powders cause more erosion in the weapon barrel but are being used increasingly because of the higher muzzle velocities obtainable by their use.

Standard Smokeless and Flashless Powders

These powders, which were formerly designated as FNH (flashless-nonhygroscopic) and NH (nonhygroscopic), are a mixture of nitrocellulose and other materials added to cool the products of combustion, thereby reducing the flash and the hygroscopicity, that is, the tendency to absorb moisture. They are used as propellants for most weapons of 37-mm and larger caliber. Nitroglycerin is used in certain powders where especially rapid burning is required and in certain high-velocity rounds and weapons.

Rounds of certain caliber, such as 3-inch, 76-mm, and 90-mm, are designated as "flashless," "smokeless," or "flashless-smokeless," depending upon flash and smoke characteristics upon firing.

Whether ammunition upon firing is flashless, smokeless, or both, depends upon the weapons in which used, the type of ignition used, weapon wear, the temperature of the tube of the weapon, and the quantity and design of the propellent powder. Flashless and smokeless are relative terms and have been defined as follows: flashless ammunition does not flash more than 5 per cent of the time in weapons of average life under standard conditions; smokeless ammunition produces less than half of the amount of smoke produced by ammunition not so designated. A complete round having both these characteristics is designated "flashless-smokeless."

Guncotton

Guncotton, a nitrocellulose of high nitration (13.35 to 13.4 per cent nitrogen) is used in the manufacture of propellents. It is also used in electric primers and in electrically initiated destructors.

EC Smokeless Powder

EC smokeless powder, or EC blank fire, consists of nitrocellulose with inorganic nitrates. It is usually orange or pink in color and resembles coarse sand, though it is soft and light. It is sensitive to friction, shock, or heat. It absorbs moisture readily and therefore must be protected from the atmosphere. It burns extremely rapidly in the open, but explodes if confined. It is usually exploded by flame from a primer or fuse. It was used at one time as a bursting charge in fragmentation hand grenades. It is used in cal. .30 and cal. .50 blank cartridges, in shotgun shells, and in cal. .22 ammunition.

Small-arms Propellants

Smokeless powder for small arms is usually glazed with graphite to facilitate machine loading and to prevent the accumulation of large charges of static electricity, and thus presents a black, polished appearance. Since the powder grains are small, they ignite more readily and burn more freely than cannon powder. When moisture is present or abnormal temperatures prevail, they are subject to more rapid deterioration than the larger grains. Many small-arms powders are nearly as sensitive to friction as black powder. Therefore, precautions used in handling black powder should be observed for small-arms powders. In general, there are two types of small-arms propellants, single-base and double-base.

A recent type of small-arms powder is in the form of small, spherical, graphite-coated balls and is used in carbine and cal. .45 ammunition.

Black Powder

General Characteristics. Black powder is an intimate mechanical mixture of finely-pulverized potassium nitrate or sodium nitrate, charcoal, and sulphur. The commercial blasting powder with sodium nitrate is now used for saluting purposes. Potassium nitrate is used in the powders for all other military purposes. Black powder is usually in the form of small, black grains which are polished by glazing with graphite. It is subject to rapid deterioration on absorption of moisture, but if kept dry it retains its explosive properties indefinitely. It is one of the most dangerous explosives to handle because it is very easily ignited by heat, friction, or spark.

Uses. In its several grades, its present military use is confined for the most part to:

Ignition and primer charges.

Expelling charges for base-ejection smoke shell, illuminating shell, and pyrotechnics.

Delay pellets for primers and fuses.

Blank ammunition charges.

Smoke-puff and spotting charges.

Precautions. Black powder is particularly sensitive to shock, friction, heat, flame, or spark. When black powder is handled in cans or bags or when it is not absolutely protected against sparks, special care must be taken.

4. HIGH EXPLOSIVES

General

High explosives are usually nitration products of organic substances, such as toluene, phenol, pentaerythritol, amines, glycerin, and starch, but may be nitrogen-containing inorganic substances or mixtures of both. Other materials, such as powdered aluminum, plasticizing oils, waxes, rubber, etc., may also be added to explosives to obtain desired characteristics.

A high explosive may be a pure compound or an intimate mixture of several ingredients. To avoid confusion in the writing of formulas of mixtures, the following order of listing of components, together with their proportions, has been decided upon: inorganic nitrates/explosives other than TNT/TNT/metals/inert materials. Within any of the preceding groups, the components are listed alphabetically should there be more than one of that particular classification.

Primer Mixtures

General. A primer mixture is an explosive sensitive to a blow such as that imparted by a firing pin. It is used to transmit shock or a flame to another explosive, a time element, or a detonator.

Composition. In a large number of mixtures, the primer mixture consists of mercury fulminate, potassium chlorate, and antimony sulfide, with or without ground glass and/or a binder. However, the chemicals and materials used may be altered, depending upon the type of action desired. Primarily, a primer mixture consists of an initiating high explosive, an oxygen carrier, and a combustible substance.

Uses. Primer mixtures are used in the percussion elements of cannon primers, in fuses, and in small-arms primers, and as the upper layer of a detonator assembly.

Mercury Fulminate

Characteristics. Mercury fulminate is a heavy crystalline solid, white when pure, but ordinarily having a faint brownish-yellow or grayish tint. It is extremely sensitive to heat, friction, spark, flame, or shock, detonating completely in nearly every instance. Its sensitivity varies with temperature. It has been found that its sensitivity is dependent in part on crystal size. It is nonhygroscopic and may be safely stored for long periods of time at moderate temperatures. However, it will not stand long-term storage at elevated temperatures.

Use. For all practical purposes, mercury fulminate has been replaced by lead azide. Its use is limited to small quantities in a few primers, in fuse detonators, and in blasting caps. It may be used alone or mixed with potassium chlorate.

Lead Azide

Lead azide is an initiating compound used to detonate high explosives. It is a fine-grained, cream-colored compound. It is sensitive to flame and impact but it is not certain to detonate by the action of a firing pin. It does not easily decompose during long, continued storage at moderately elevated temperatures. It flashes at a much higher temperature than mercury fulminate. A smaller weight of lead azide than of mercury fulminate is required to detonate an equal amount of TNT, tetryl, etc. Lead azide is replacing mercury fulminate because of its properties and because it stands up better in storage and is less hazardous to manufacture. It is found in primer mixtures and in detonator assemblies in fuses.

Tetryl

Characteristics. Tetryl (trinitrophenylnitramine) is a yellow, crystalline solid. When heated it first melts and then decomposes and explodes. It burns readily and is more easily detonated than TNT or ammonium picrate, being much more sensitive than picric acid. It is detonated by friction, shock, or spark. It is practically nonhygroscopic. Tetryl is stable at all temperatures which may be encountered in storage.

Detonation. Brisance tests show tetryl to have a very high shattering power. It is greater in brisance than picric acid or TNT and is exceeded only by PETN and some of the newer military explosives, such as RDX.

Use. Tetryl is used as a charge and as a detonator.

Charges. Tetryl is the standard booster explosive and is sufficiently insensitive when compressed to be used safely as a booster explosive. The violence of its detonation insures a high-order detonation of the bursting charge. It is used in the form of pressed pellets. Tetryl is the standard bursting charge for small-caliber (20-mm and 37-mm) projectiles. It produces appreciably better fragmentation of these shells than TNT. It is also more readily detonated and yet in small-caliber shell withstands the force of set-back in the weapon. It is also a component of tetrytol.

Detonator. Tetryl is used in detonators, the tetryl being pressed into the bottom of the detonator shell and then covered with a small priming charge of mercury fulminate, lead azide, or other initiator.

TNT (Trinitrotoluene)

General. Although trinitrotoluene was known as early as 1863, it was not suggested as an explosive until about 1890, and its importance from a military standpoint dates from 1904. Since that time, it has appeared as the principal constituent of many explosives, and has been used by itself under such various names as triton, trotyl, tolite, trilite, trinol, tritolo, etc. It is commonly known in this country by the abbreviation TNT. The term trinitrotoluol, which is more generally used than trinitrotoluene, is less correct from the chemical point of view than the latter.

Characteristics. TNT when properly purified is one of the most stable of high explosives and can be stored over long periods of time. It is relatively insensitive to blows or friction. Confined TNT, when detonated, explodes with violence. When ignited by a flame, unconfined TNT burns slowly without explosion evolving a heavy oily smoke; however, burning or rapid heating of large quantities, especially in closed vessels, may cause violent detonation. It is readily detonated by mercury fulminate, tetryl, and similar high explosives. It is nonhygroscopic and does not form sensitive compounds with metals, but is readily acted upon by alkalies to form unstable compounds which are very sensitive to heat and impact. It usually resembles a light brown sugar, but when pure is crystalline and is nearly white. Easily melted and poured into a shell or bomb to form a solid crystalline explosive charge, TNT is a very satisfactory military explosive. The melting point of standard Grade I TNT is 80.2°F.

Ammunition loaded with TNT can be stored, handled, and shipped with comparative safety. Both grades of TNT are slightly toxic, and it is necessary that proper precaution be taken by those engaged in its manufacture or handling to avoid inhaling the vapors or dust from the molten or crystalline material. Good ventilation in manufacturing or shell-loading plants is highly essential, and personal cleanliness should be enforced.

THIS PAGE IS DECLASSIFIED IAW EO 13526

Exudation. When stored in warm climates or during warm summer months, some ammunition loaded with TNT may exude an oily brown liquid. This exudate oozes out around the threads at the nose of the shell and may form a pool on the floor. The exudate is inflammable and may carry small particles of TNT. Pools of exudate should be removed.

Detonation. TNT in crystalline form can be detonated readily by a No. 6 blasting cap or when highly compressed by a No. 8 blasting cap. When cast, it is necessary to use a booster charge of pressed tetryl or an explosive of similar brisance to insure complete detonation.

Use. Bursting Charge. TNT is used as a bursting charge for high-explosive shells and bombs either alone or mixed with ammonium nitrate to form 50/50 or 80/20 amatol. Flake TNT is used in 37-mm shells and in fragmentation hand grenades. Other military uses of TNT are in mines and for parts of certain shell and bomb bursters.

Ammonium Picrate (Explosive D)

Characteristics. Ammonium picrate is the least sensitive of military explosives to shock and friction. This makes it well suited for use as a bursting charge in armor-piercing projectiles. It is slightly inferior in explosive strength to TNT. When heated, it does not melt but decomposes and explodes. It reacts slowly with metals, and when wet it may form sensitive and dangerous compounds with iron, copper, and lead. It is difficult to detonate but burns readily like tar or resin.

Special Precautions. Ammonium picrate, which has been pressed at a shell-loading plant and removed from a shell, is much more sensitive to shock or blow than fresh ammonium picrate. It should be protected against shock or fire and should preferably be stored alone in a building. Although less sensitive than TNT, it can be exploded by severe shock or friction, is highly inflammable, and may detonate when heated to a high temperature.

Use. Explosive D is used as a bursting charge for armor-piercing shell, in projectiles for seacoast cannon, and in other types of projectiles which must withstand severe shock and stresses before detonating.

Picratol

General. Picratol is a mixture of 52 per cent explosive D and 48 per cent TNT. It can be poured like straight TNT and has approximately the same resistance to shock as that of straight explosive D. The brisance of picratol is between that of explosive D and TNT. Picratol is nonhygroscopic.

Use. Picratol is a standard filler for all Army and semiarmor-piercing bombs.

Tritonal

Tritonal is a generic term for explosives containing TNT and aluminum, generally in the ratio of 80/20. It produces a greater blast effect than TNT or Composition B described below. It is used in light-case and general-purpose bombs.

RDX

RDX is also known as "cyclonite" (cyclotrimethylenetrinitramine), CTMTN, C6, hexogen (German), and T4 (Italian). It is a white crystalline solid having a melting point of 202° C. It has about the same power and brisance as PETN. It is more easily initiated by mercury fulminate than is tetryl. It has a high degree of stability in storage. RDX is never used alone but in mixtures with other explosives and or oils and waxes.

Torpex

Torpex is a gray compound consisting of RDX, TNT, aluminum powder, and beeswax (or similar wax). It is a more powerful but much more sensitive explosive than TNT. Torpex is nonhygroscopic, noncorrosive, and has a very high brisance. Under water it is 50 per cent more destructive than TNT, whereas in air the difference is approximately 30 per cent. Torpex is used as a bursting charge in mines, torpedoes, and depth charges.

Composition B

Composition B (Comp. B) is a mixture of RDX, TNT, and beeswax or similar wax. It is a nonplastic material which is cast-loaded. It is one of the most powerful explosives. It is less sensitive than tetryl but more sensitive ing for AN (Army-Navy) standard aircraft bombs, mines, and torpedoes, and may be used than TNT. Composition B is an authorized fill-in boosters for large bombs, demolition charges, and larger-caliber projectiles.

SECTION II—AMMUNITION

1. SMALL-ARMS AMMUNITION

Definitions

Small-arms ammunition is used in weapons having a bore inside of barrel of 0.60 inch or less in diameter. (Carbine—0.30 inch; Pistol—0.45 inch; Submachine Gun—0.45 inch; Machine Gun—0.50 inch.)

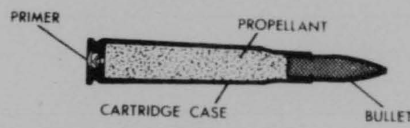

Figure 6—4. Complete Round.

Complete Cartridge (Round)—a complete unit consisting of all the parts necessary to fire the weapon once. The four major parts of a small-arms cartridge are the primer, propellent powder (propelling charge), bullet (projectile) and cartridge case. (Figure 6-4).

Primer. Located in the rear (head) of the cartridge, and used to set off the propellent powder. It consists of:

A cup—made of soft metal. (Figure 6-5).

A primer composition (primer mixture) made of a nonmercuric or noncorrosive explosive. Lead azide is usually used.

A disc—made of shellacked manila paper.

An anvil—made of brass.

The cup holds the primer composition (mixture) which is held in place and protected from moisture by the disk. The anvil fits over the disk in the cup. A blow from the firing pin (in the weapon) on the primer cup pinches the

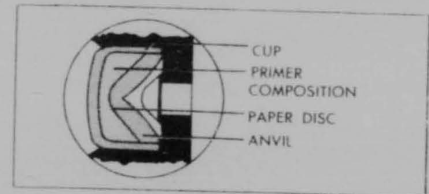

Figure 6—5. Primer Assembly.

primer composition between the cup and the anvil, thereby starting a flame.

Propellent Powder. Located within the cartridge case, consists of a quantity of smokeless powder which is a low explosive. The flame from the primer composition passes through the vents (passages) in the anvil and cartridge case and ignites the propellent powder. Expanding gases result from the burning of the powder creating pressure which propels (forces) the bullet out of the cartridge case, and through the barrel of the weapon.

Bullet. Located in the front (neck) of the cartridge case, and used to strike the target and cause the desired result. For example: wound, kill, set on fire, penetrate armor, etc. It consists of the following:

A jacket—made of gilding metal (90 per cent copper and 10 per cent zinc alloy), serves two purposes. One, the lands cut into the jacket and cause rotation of the bullet, giving it the necessary stability in flight. Two, it fits the bore tightly thus preventing the escape of gas past the bullet. The bore of a military weapon is always measured from the top of one land to the top of the opposing land. As an example, the cal. .50 is 50 hundredths of an inch (.50) from one land to the opposite land. The land depth is 5 thousandths (.005) of an inch. With the two lands the total is 10 thousandths (.010) of an inch, thereby giving a groove to groove measurement of 5 hundred and 10 thousandths (.510) of an inch. The bullet must then have 1 thousandth of an inch (.001) additional gilding metal added to its diameter, giving a total bullet diameter of .511 of an inch. The gas seal is now accomplished and the lands must cut into the jacket to give rotation to the bullet. (See Figure 6-6).

Core (filler of the bullet)—made of lead alloy, common steel or hardened steel alloy, tracer, or incendiary.

Point filler—lead, antimony-lead, or incendiary.

THIS PAGE IS DECLASSIFIED IAW EO 13526

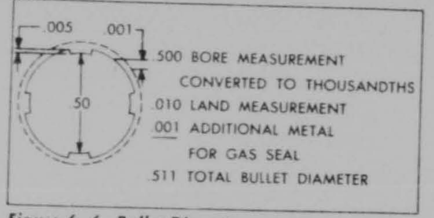

Figure 6–6. Bullet Diameter.

Base filler (base seal)—gilding metal, tracer composition, or some other filler.

Cannelure—the groove around the bullet—prevents the bullet from being pushed back into the cartridge case during automatic feeding of the weapon, and rough handling.

Ogive—streamlined portion at front of bullet.

Meplat—nose of the bullet. Tends to reduce ricochet. Does not prevent ricochet.

Conicle taper—(Boattail-type bullet only)—at the rear of the bullet.

Cartridge case is made of brass in most cases but may be made of steel. It has three functions: holds the other major components together as a unit, provides a waterproof container for the propellent powder, and when the cartridge is fired, it prevents the escape of gases to the rear by expansion of the thin side walls causing them to adhere to the walls of the chamber by the pressure. The component parts of the cartridge case are:

The mouth—opening for insertion of propellant and bullet.

The lip—edge of mouth to be crimped into the cannelure.

The neck—holds the bullet in place. A thin coat of varnish is applied inside the neck to waterproof the propellant.

Shoulder—the taper between the neck and the body. It must conform to the profile of the chamber.

Body—acts as a basis for the other component parts.

Wall—the average thickness of the brass in the body.

Head—the thickness of the brass at the base of the cartridge case that provides a place for the extracting groove, primer pocket and primer vent.

Primer pocket—a pocket punched in the head to hold the primer.

Primer vent—a passage punched from the primer pocket into the propellent cavity to allow the flame or spark of the primer mixture to ignite the propellant.

Extracting groove—the groove at the head of the cartridge case that allows the removal of the spent case from the chamber by a mechanical extractor.

Propellent cavity—inside of the case that holds the propellant. (See Figure 6-7).

The cartridge case is made from a circular disk of brass which is punched into the form of a cup. The cup is then drawn through dies until its proper shape is formed. The closed end is then pressed into shape. The manufacturer's initials and primer pocket are punched. The extracting groove is then machined.

There are annealing and washing processes between the draw and punching stages. The final case has a hard tough head to withstand the pull of extraction, and the side walls are soft but resilient (springy) enough to spring back after expansion. The mouth of the case is annealed to a dark bluish color to prevent season cracking. The cases then go to the pierce and prime process where the primer vent is punched and the primer is staked in place. The loading process is next. The case is loaded with a charge of propellent powder and the inside of the neck is coated with varnish or lacquer. The bullet is inserted and the lip is crimped into the cannelure. Cal. .30 carbine and cal. .45 cartridges are not crimped but held in place by the tight fit of the bullet.

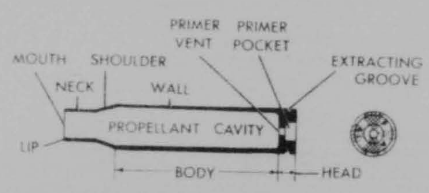

Figure 6–7. Cartridge Case.

Color of bullet tip	Type of cartridge
No Color	Ball
Black	Armor-piercing
Aluminum	Armor-piercing-incendiary
Red	Tracer Cal. .50 M1 M-21 Carbine M-16 Cal. .45 M-26
Maroon	Tracer Cal. .50 M17
Orange	Tracer Cal. .50 M10 Carbine M27
Red/w/aluminum color rear annulus	Armor-piercing - incendiary-tracer
Blue w/light blue rear annulus	Incendiary Cal. .50M23
Blue w/aluminum color rear annulus	Armor-piercing incendiary cal. .50T49
Green w/white rear annulus	Frangible

Classification

Small-arms ammunition is classified according to its purpose, as service (combat) or special-type ammunition.

Service-type ammunition. Ball—for use against personnel and light-material targets.

Tracer—for observation of fire. Secondary purposes are for incendiary and signaling.

Incendiary—to start fires, especially against aircraft.

Armor-piercing—used against armored aircraft.

Armor-piercing incendiary—for combined armor-piercing and incendiary effect.

Shot—used for hunting small game with the cal. .45 pistol (contains #7½ chilled shot).

Grenade—used for launching rifle grenades by means of a rifle or carbine equipped with a grenade launcher.

Special-type ammunition. Dummy—used for training purposes, such as loading and unloading of weapons (completely inert).

Blank—for firing salutes (no bullet).

High-pressure test—for use only in proof firing of weapons. Testing the strength of weapons.

Frangible—for target practice against specially-armored aircraft. The bullet disintegrates upon hitting the aircraft. The bullet is made of plastic and lead.

Identification of Ammunition Types

In general, all types of cartridges of one caliber have the same profile. They may be identified, except as to ammunition lot number and grade, by the physical characteristics that have been explained and by the color of the bullet tip. The colors of the various types are listed in the table below.

Range

The range of the various types of ammunition is listed below. Maximum range is the greatest distance the gun can fire, and the range of trace is the greatest distance the tracer color is visible.

Caliber .30 carbine	
Ball, M1, Max. Range	2,200 Yds
Tracer, M16, Max. Range	1,680 Yds
Max. Trace	570 Yds
Caliber .45 Pistol	
Ball, M1911, Max. Range	1,640 Yds
Shot, M12, and M15 - Not Given	
Tracer, M26, Max. Range	1,600 Yds
Max. Trace	260 Yds
Caliber .50 Machine Gun	
Ball, M2, Max. Range	7,275 Yds
AP M2, Max. Range	7,275 Yds
API M8, Max. Range	6,375 Yds
API T49, Max. Range	5,500 Yds
API-T M20, Max. Range	6,375 Yds
Max. Trace	1,800 Yds
Incandiary, M-1	
Max. Range	5,960 Yds
Tracer, M1, Max. Range	5,470 Yds
Max. Trace	1,800 Yds
Tracer, M10, Max. Range	5,350 Yds
Max. Trace Dim	150 Yds; Bright to 1900 yds.
Tracer, M17, Max. Range	5,350 Yds
Max. Trace	2,450 Yds
Tracer, M21, Max. Range	5,470 Yds
Max. Trace	550 Yds

Grades of Ammunition

Ammunition is manufactured to strict requirements, and is inspected and tested thoroughly before acceptance. Since the various types of weapons—carbines, pistols, machine guns, etc.—have different requirements, production orders and specifications call for the classification of lots of ammunition for use in specific weapons.

Differences in manufacture may occur because of problems of mass production of ammunition. Considering differences from lot to lot and the different requirements for each type of weapon, grades are assigned to each lot of ammunition, in accordance with inspections and acceptance tests, to designate their use in the different types of weapons.

Grades for cal. .30 carbine ammunition.
R—Carbines.
3—Unserviceable, not to be issued or used.

Grades for cal. .45 ammunition.
1—Revolvers, pistols and submachine guns.

2—Pistols and submachine guns only.
3—Unserviceable, not to be issued nor used.

Grades for cal. .50 ammunition.
AC—Aircraft and antiaircraft machine guns.
MG—Ground machine guns.
3—Unserviceable, not to be issued nor used.

When small-arms ammunition becomes unserviceable, it is graded as grade 3 and withdrawn from service. Ammunition which cannot be identified will be considered as grade 3. However, unidentified ammunition will not be classified as unserviceable until every effort has been made to establish its identity.

Current grades of all existing lots of small-arms ammunition are made by the Chief of Ordnance as a result of inspection, and are published in SB 9-Ammo 4.

Ammunition Lot Number

Although small-arms ammunition is produced on a continuous, mass-production basis, a difference is made between the quantities of completed cartridges which contain identical component items or materials. For purposes of identity and accounting, each quantity of ammunition is identified by a lot number. Different blocks of lot numbers (in thousands) are assigned to each manufacturer. The manufacturer's initials are also designated as part of the ammunition lot number. (Examples are listed below.)

Denver Ordnance Plant	DEN
Des Moines Ordnance Plant	DM
Frankford Arsenal	FA
Remington Arms Company	RA or REM
St. Louis Ordnance Plant	SL
Utah Ordnance Plant	UT or U
Winchester Repeating Arms Co.	WRA

Each manufacturer is authorized to assign the same lot number to one lot of each type or each caliber manufactured at that plant. It is, therefore, essential that each ammunition lot be identified by its ammunition identification code (AIC) or its standard nomenclature, together with its lot number.

Ammunition Identification Code

An ammunition identification code (AIC) has been established to facilitate the supply of ammunition in the field. The AIC symbols are used for identifying ammunition items in messages, requisitions, and records. Once an AIC is assigned to any item of ammunition it will never be changed. The AIC always consists of five characters: the first, third, fourth, and fifth are capital letters; the second is an arabic numeral. In general, the following meanings are attached to these characters.

1st and 2d characters—the SNL in which the item is listed.

3rd character—the weapon or group of weapons.

4th character—the type and model of ammunition.

5th character—the kind or method of packing.

T1EDV is a typical AIC. The first two characters mean that this item of ammunition is listed in ORD 11 SNL T-1. Ammunition of different types (ball, AP, TR, etc.) having the same lot numbers must be accompanied by the AIC, and the fourth character of the AIC will show that the ammunition is of a different type. Example:

FA 8000	T1EDV	Ball ammunition
FA 8000	T1EEV	AP ammunition
FA 8000	T1EHV	Tracer ammunition

Packing

The containers and methods for packing small-arms ammunition are given in drawings, specifications, and standard nomenclature lists. Present containers have been reduced to a few standard types to withstand all conditions commonly encountered in handling, storing, and transporting the ammunition.

With few exceptions, small-arms ammunition is issued in metal containers packed for shipment in wooden boxes. There are two types of metal containers; hermetically sealed cans opened by means of a key and tear strip, and the metal boxes having hinged covers sealed by means of a rubber gasket. The first type is used for packing cal. .30 carbine, cal. .45 and some cal. .50 ammunition. The outer containers are either wooden packing boxes or wire bound crates.

Markings of packing containers. The outer containers are stained or painted dark brown

THIS PAGE IS DECLASSIFIED IAW EO 13526

(chocolate) with the stenciling or printing in yellow, or unstained with stenciling or printing in black. All metal containers are olive drab with markings in yellow.

Safety Precautions

Small-arms ammunition, as compared with other types of ammunition, is not dangerous to handle. Care, however, must be observed to protect the primers from being struck by any sharp instrument as such a blow might explode the cartridges.

Small-arms ammunition is not an explosive hazard in storage, although under adverse conditions it may become a fire hazard. It is advisable to keep personnel not engaged in fighting the fire at least two hundred yards distance and have them lie flat on the ground due to the hazard of flying bullets and cartridge cases.

Tracer ammunition should be stored separately from other ammunition if practicable.

The use of grease or oil on cartridges is prohibited. These agents cause injurious abrasives to collect in automatic weapons and produce excessive and hazardous pressures on the rifle bolts when non-automatic rifles are fired.

Ammunition should always be stored under cover when possible and kept well ventilated. If ammunition must be stored in the open, it should be stacked on dunnage at least six inches from the ground and be covered with a double thickness of serviceable tarpaulin.

Ammunition should not be opened until ready for use.

If an ammunition box is broken, the box should be repaired immediately. All markings should be transferred to the new part of the box.

2. 20-MM AMMUNITION

Major Component Parts

20-mm ammunition differs from small arms ammunition in that they have an additional component part. The high-explosive rounds have two additional component parts. The parts are as follows:

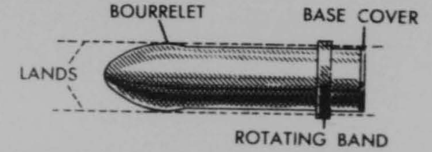

Figure 6–8. 20 MM Ammunition.

Cartridge case.
Propellant charge.
Primer.
Projectile.

Rotating Band (Figure 6-8). Located on the lower portion of the projectile. It is made of copper or gilding metal and has a slightly greater diameter than the raised part of the riflings. This allows the lands to cut into the metal and give rotation to the projectile to stabilize it in flight; it also prevents the gases from escaping past the projectile.

Fuse (with high explosive rounds only).

Bourrelet (Boor-Lay). A very accurately-machined portion on the forward part of the projectile that rides on top of the lands. It acts as a forward bearing surface and prevents the projectile from wobbling in the bore.

Base Cover. The base cover is used with the high-explosive round only. It is a metal disk that is electrically welded to the base of the projectile. Its purpose is to prevent premature explosions due to cracks or flaws in the metal.

Classification of 20-mm Ammunition

20-mm ammunition is classified according to the projectile used. The standard projectiles used are:

High Explosive Incendiary (HE-I). The projectile contains both a high-explosive and an incendiary mixture.

Incendiary (I). Projectile contains an incendiary mixture only.

Armor Piercing With Tracer. (Figure 6-9). The projectile is machined from cold-drawn bar steel. The radius of the ogive is rounded giving it a blunt appearance. A windshield or false ogive is added so that when the projectile strikes the target, the windshield folds back and acts as a guide to prevent ricocheting off the target. A cavity is machined into the back of the projectile to receive the tracer. The

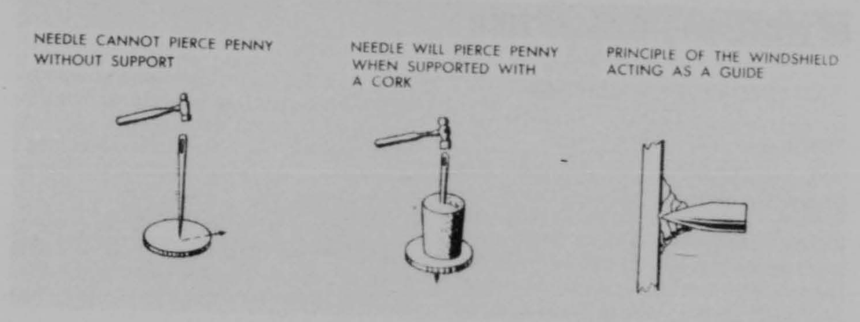

Figure 6–9. Principle of AP Ammunition.

tracer is ignited by the heat of the propellant.

Ball. The projectile is hollow in the center and is inert.

High Explosive–Incendiary Cartridge

The HE-I round is generally fired from aircraft guns against enemy aircraft, although it may be directed against light ground targets and personnel.

Complete Round. The complete round consists of all the major component parts necessary for a high-explosive round plus a high-explosive filler and an incendiary mixture which are located in the projectile.

Fuze. The fuze is classified as an instantaneous percussion fuze of the impact type which can go thru material and act on heavier material of the aircraft. The fuze has a primer of mercury fulminate, a detonator of lead azide, and a relay detonator of tetryl. The fuze is screwed into the projectile which has a bursting charge of tetryl and the incendiary mixture.

Identification of 20-mm Cartridges

20-mm cartridges is identified as follows:

HE-I. The fuze is brass. From the base of the fuze to the bourrelet is painted yellow. From the bourrelet to the rotating band is painted red with "Shell, HE-I 20-mm" and M (model number) painted in black. The rotating bands are never painted on any ammunition. The primary reason for painting artillery projectiles is to prevent rust and secondly to have a ready means of identifying them.

AP-T. The entire projectile is painted black with markings "Shot, AP, 20-mm" and M (model number) with tracer painted in white below the bourrelet.

Ball. The entire projectile is painted black. There are no markings.

Safety Precautions in Handling 20-mm Ammunition

The ammunition should be handled with care at all times. The explosive elements in the primer and fuzes are highly sensitive to shock and high temperature.

No attempt should be made to disassemble any fuze or complete round. This practice is prohibited.

Although the use of oil and grease is generally prohibited, it is necessary with 20-mm ammunition to prevent jamming. A light coat of oil is applied just prior to insertion in the magazine or belt. Extreme caution should be exercised to prevent the oil from saturating the primer or mouth of the cartridge case.

Dud ammunition is not to be handled. Dud ammunition is ammunition that has been fired and did not detonate. It will be disposed of by authorized and qualified personnel.

SECTION III—BALLISTICS

1. THE THEORY OF BALLISTICS

Definition

Certain characteristics of cartridges and particularly of their discharge in firearms are referred to as the "ballistics" of ammunition. The term ballistics comes to us through the original Greek root word, "balleiu" meaning to throw. It is defined as the science of motion of projectiles. It is a study of various forces, controllable and uncontrollable, which govern the movement of projectiles. Ballistics are divided into two branches, internal and external ballistics.

Internal ballistics of a cartridge are those functions that take place after firing the weapon, but before the projectile has left the muzzle end of the barrel. They include the chamber pressure expressed in pounds per square inch (Figure 6-11); the curve of pressure as the projectile progresses through the barrel, expressed by means of a graph; the free recoil of the weapon, expressed in foot pounds; the time of travel, expressed in thousandths of feet per second. (See Figure 6-10).

External ballistics describes the action of the projectile after it has left the muzzle end of the barrel, including the various affecting factors, which are: muzzle velocity expressed in feet per second, and is measured in the first second of flight, as the projectile leaves the muzzle end of the weapon. The remaining or average velocity is expressed on distance or a given range.

Trajectory is the path that the projectile takes, between the muzzle of the gun, and the point of impact. The path of the projectile is affected by the following factors (See Figure 6-11).

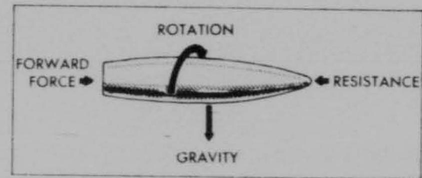

Figure 6–11. Four Factors Affecting Projectiles.

Force. The pressure exerted from explosion of the propellant against the rear of the projectile.

Rotation. The speed of rotation of the projectile depends upon the amount of twist in the rifling and the velocity of the projectile. The spin of the projectile causes it to drift laterally. For example when the cal. 30.06 rifle is fired the bullet will drift slightly to the left up to 500 yards, and then over to the right. This is due to the lateral jump when the weapon is fired. The rotation effect of the bullet stabilizes it in flight.

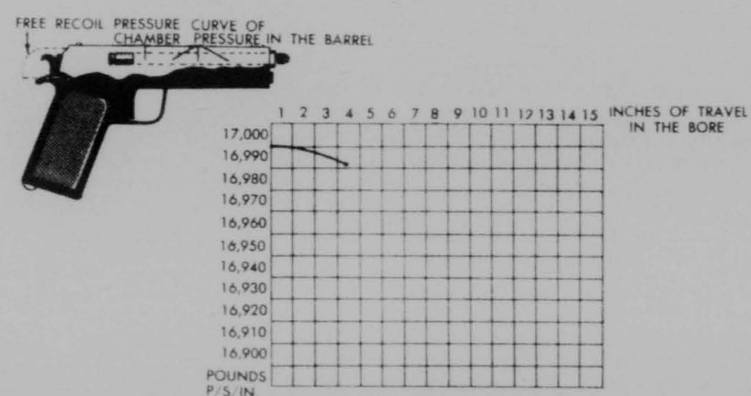

Figure 6–10. Internal Ballistics.

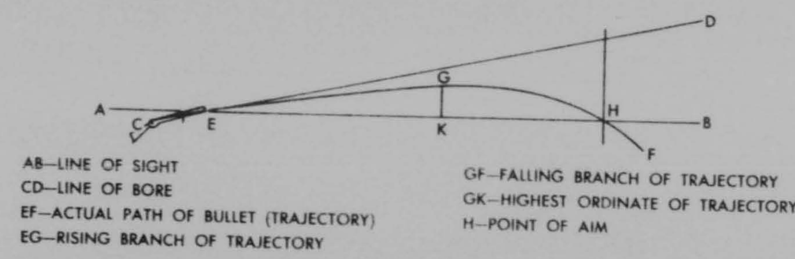

Figure 6–12. Trajectory, Vertical Scale Exaggerated.

Resistance. The travel of the projectile through the atmosphere will cause a reduction in speed. The further the range the slower the projectile. When the velocity is increased the resistance also increases. The air resistance increases with increased velocity at a rate equal to the square of the increase in velocity. Thus a bullet at 2000 feet per second meets four times the resistance of the bullet at 1000 feet per second.

Gravity. A freely falling body accelerates at the rate of 32 feet per second. This force acting on a projectile causes it to drop 16 feet during the first second, 48 feet during the second second, and 80 feet during the third second, et cetera. The line of sight is level and straight from the eye to the target. Therefore, the sights on a weapon must be so arranged that the barrel is pointed upward, and when the weapon is fired the actual path of the projectile will then rise above the line of sight and come back to the line of sight at its target. The arching of the projectile in its trajectory is called **rising branch.** The point where the projectile begins to fall is called the **falling branch.** The extreme height of the trajectory, above the line of sight at any point is called the "ordinate" of the trajectory. (See Figure 6-12).

In military terms the danger space or point-blank range of a cartridge is the total distance over which the highest ordinate of trajectory does not exceed one half of the height of a standing man plus the distance beyond coincidence of the point of aim. Thus, when aiming at a man's belt buckle the bullet will not pass above his head nor below his feet.

Modern ammunition and weapons have greatly increased the danger space by their higher muzzle velocity and more effectively shaped projectiles. During the eighteenth century the danger space of small-arms ammunition was 125 yards. Present day military loads average 600 yards or better.

Muzzle or impact energy is the striking force of the projectile at the muzzle end of the barrel or at any given point along the path of trajectory of the projectile. It is expressed in foot pounds. Foot-pound is a unit of energy required to raise one pound of avoirdupois one foot against the force of gravity.

Extreme range is the distance over which a projectile will travel, before it will hit the ground, when the barrel of the weapon is held at the proper angle to give maximum efficiency.

Barrage range is used in machine-gun fire and denotes the distance a series of shots can be controlled so that they will score hits on the target with little dispersal.

Cone of fire is the pattern made by a number of shots fired from one or more weapons at the same target.

Uniformity of Ammunition

In firing any type of ammunition from a weapon, accuracy depends on uniformity as to

THIS PAGE IS DECLASSIFIED IAW EO 13526

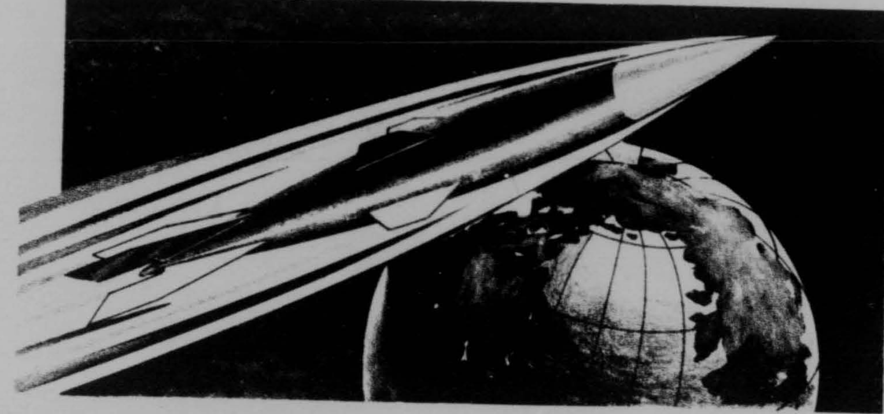
the shape of the projectile, weight, concentricity, seating, crimping, case size, powder charge, powder characteristics, primer, and the over-all dimension. The variation of air between shots will result in very little deviation of the projectile, assuming that the air remains constant. But the projectile is affected chiefly by what happens inside the barrel or in the manufacture of the weapon and the ammunition.

Future development and further study is in progress to increase the accuracy and efficiency of weapons and ammunition. The great difficulty encountered in trying to speed up the velocity of projectiles is the rapid wearing away of the riflings within the weapon. However, much progress has been achieved in reaching a much higher velocity over what books and pamphlets now state.

2. SUMMARY

In the foregoing statements and conclusions, only the basic factors of the ballistics problem has been touched. A multitude of complicated problems and study still remains in this field. They are too complex for inclusion in this text.

CHAPTER 7—BOMBS, ROCKETS AND FUZES



SECTION I—BOMBS AND RELATED FUZES

1. HISTORY

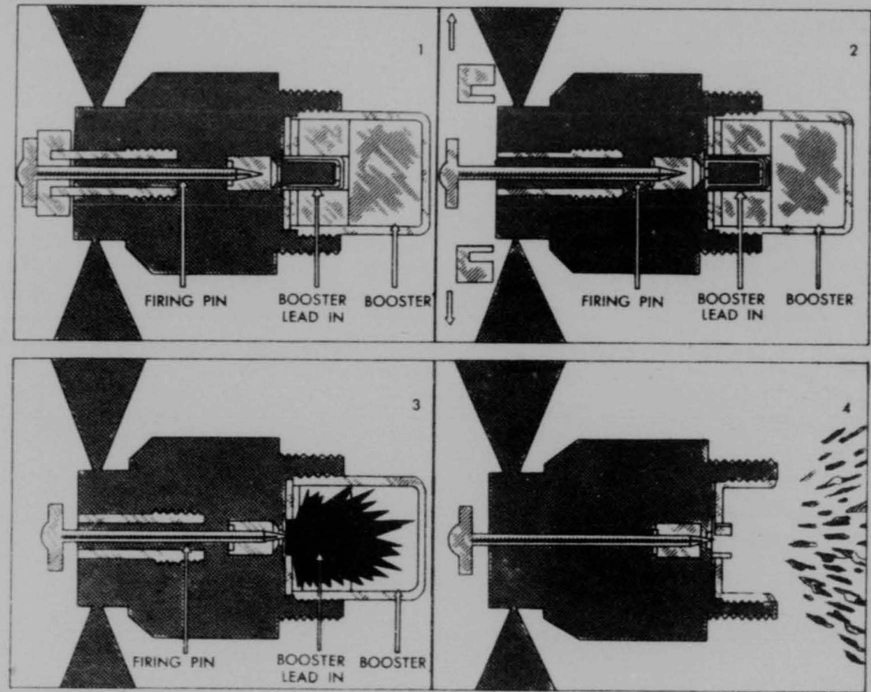
General

Fleets of bombers operated over vital enemy targets and at great distances from their home base during World War II. They proved themselves to be of great strategic value. Warfare as carried on by prehistoric man, who dropped rocks and spears from cliffs and trees upon his enemy, was only the beginning of the highly technical practice of bombing as it was accomplished during the last war. As the years went by, man became more advanced and made new discoveries. Yet as his armies became more complex, it was still found advantageous to fight from heights to gain the "upper hand" over his enemy.

Developments After World War I

At the end of World War I, the civilized world fully realized the value and importance of the airplane and the high-explosive bomb as an offensive weapon. During the years following the war, there was great activity in bomb and bomb-fuze development as well as in the field of bomb ballistics. When bombs were first used, they were suspended vertically, nose down in a rack. It was soon discovered that this was not the correct position and that a bomb must be started off in a horizontal position tangent to its true trajectory. As the lifting power of aircraft increased so did the size of the bombs (from 600 pounds to 4000 pounds within a period of two years). The first 4000-pound bomb was made in 1921, although the United States had only one type of plane which would carry one of these bombs. Careful studies were made in the field of tactical uses for bombs. Experiments were carried out to determine the economical limits of sizes for various bombs. It was decided that there should be three types: **fragmentation bombs**, **chemical bombs**, and **demolition bombs**.

THIS PAGE IS DECLASSIFIED IAW EO 13526



1. THE BOMB IS IN FLIGHT, BUT THE ARMING ACTION (IN THIS CASE A PROPELLER-LIKE VANE, SPINNING IN THE AIR STREAM) STILL HOLDS A COLLAR BETWEEN THE STRIKER HEAD (WITH ITS FIRING PIN) AND THE PRIMER.
2. NOW THE COLLAR HAS BEEN RELEASED AND FLIES OFF IN THREE PARTS.
3. THE BOMB HAS STRUCK, THE FIRING PIN IS FORCED INTO THE PRIMER, WHICH DETONATES THE BOOSTER LEAD-IN. THIS IN TURN DETONATES THE BOOSTER.
4. THE BOOSTER'S DETONATION SETS OFF THE BOMB'S MAIN EXPLOSIVE CHARGE.

Figure 7—1. Explosive Train.

"Frags" were to be used solely against personnel in the open. Chemical bombs were to be used whenever it was desired to prevent enemy observation of troop movement. Demolition bombs were to be used for the destruction of material targets.

2. THE BOMB

Definition

A bomb is defined as an item of ammunition dropped from an aircraft, and consists of case filled with explosive or chemical agents, and a means of exploding or scattering the charge at the target. Aircraft torpedoes, submarine mines planted by aircraft, rockets, pyrotechnics, and mortar bombs will be described later.

The Explosive Train

A bomb body is filled with high explosive. One characteristic of this explosive is that it is insensitive to ordinary shock and heat. To make it detonate, a smaller quantity of more sensitive explosive must be detonated in immediate contact with it. In a small-arms cartridge, smokeless powder, relatively insensi-

tive, is ignited by the very small but very sensitive primer. But even with more insensitive explosives like TNT a small primer is not enough; it must be amplified by a detonator of less sensitivity and larger quantity. In the larger type of bombs, this in turn must be amplified by a "booster" of medium sensitivity and medium quantity. The booster is often a part of the fuze. In very large bombs there may be a succession of boosters. The succession of charges from primer to main explosive charge is called the "explosive train" (Figure 7-1).

3. CLASSIFICATION

In common with other types of ammunition, bombs are classified according to filler as explosive, chemical, and inert. Explosive bombs are classified according to their use as **armor-piercing (AP)**, **semi-armor-piercing (SAP)**, **general purpose (GP)**, **depth**, **fragmentation**, and **practice.** Chemical bombs are classified according to type of filler, as **gas**, **smoke**, and **incendiary.** Inert bombs are used for practice and drill. Each of these types is described in detail in the following sections.

4. IDENTIFICATION

General

Bombs are completely identified by the standard nomenclature and the ammunition lot number which are stenciled on all packings, and, where the size of the item permits, on the item itself.

Standard Nomenclature

Standard nomenclature is established in order that each item stored and issued by the Ordnance Department may be specifically identified by name. It consists of the name, type and weight of the item and the model designation. The standard nomenclature lists (SNL) for bombs and components are SNL's, S-1, S-2, and S-3. The use of standard nomenclature is mandatory for all purposes of record, except as described in "Ammunition Identification Code."

Model

In order to distinguish between different designs of the same type, a model number is assigned at the time a design is adopted as standard. The model designation consists of the letter M followed by an arabic numeral. Modifications of the original design are indicated by the addition of the letter A and the appropriate arabic numeral to the model designation. For example, M38A2 designates the second modification of the item originally adopted as M38. Certain items have been standardized for use by both Army and Navy. This is indicated by prefixing the letters AN to the model. Items of Navy design are designated by Mark (MK) instead of model and modification by Mod. (For example, AN-Mk. 24-Mod2.)

Ammunition Lot Number

When ammunition is manufactured a lot number is assigned in accordance with pertinent specifications. The lot number represents a quantity of ammunition items, or ammunition components, which have been manufactured under conditions as nearly identical as possible, and which may, therefore, be expected to function uniformly. It consists of a series of letters and numerals representing the loader's lot number, the loader's symbol or initials and the date loaded. The ammunition lot number is required for purposes of record involving the particular ammunition, especially reports on condition, functioning, or accidents.

Ammunition Identification Code

In order to facilitate requisitions and records in the field, a five-character code symbol is assigned each item of ammunition issued. These code symbols are listed in ammunition SNL's.

Data Card

The ammunition data card is a five by eight inch card prepared for each lot of ammunition and forwarded with each shipment of ammunition. In addition to the ammunition lot number, it gives the lot numbers of the components and other pertinent information concerning the lot of ammunition. When required, instructions for assembly are printed on the reverse of the card.

BOMB	BODY	BANDS	MARKING
HIGH EXPLOSIVE: (G.P., Demo., AP., SAP., Frag*)			
Filled with TNT or Amatol	Olive Drab	Nose: One ½" yellow Tail: One ½" yellow	Black
Filled with Comp B	Olive Drab	Nose: Two ½" yellow Tail: Two ½" yellow	Black "Comp B" stenciled on one nose band and one tail band.
PRACTICE	Light Blue	None	White
DRILL	Olive Drab	Nose: One ½" black Tail: One ½" black	Black: Drill (inert)
CHEMICAL			
Nonpersistent gas	Blue-Gray	1 Green, nose, tail, and center	Green
Persistent gas	Blue-Gray	2 Green, nose, tail, and center	Green
Irritant smoke (Vomiting gas)	Blue-Gray	1 Red, nose, tail, and center	Red
Screening Smoke	Blue-Gray	1 Yellow, nose, tail, and center	Yellow
Incendiary	Olive Drab	1 Purple, nose, tail, and center	Purple

* Small fragmentation bombs: nose and tail painted yellow (no bands),
Body ---------- Olive Drab.

MARKING: FUZES

Fuzes are stenciled or stamped with type and model, lot number, number, and length of delay.

PAINTING AND MARKING: PRIMER DETONATORS

Head Painted:
All black - 0.1 Sec. delay
½ black - 0.05 Sec. dealy
¼ black - 0.025 Sec. delay
1/8 black - 0.01 Sec. delay
All white ------------ Nondelay

Figure 7—2. Painting and Marking Bombs.

5. PAINTING AND MARKING

Painting

Ammunition is painted to prevent rust and to furnish by colors a ready means of identification as to type. In addition bombs stored in the open are painted to prevent their ready detection from the air. High explosive, incendiary, and drill bombs are painted lusterless olive drab with bands to indicate the type. The colors used for these bands are yellow for high explosives, and black for drill. Fragmentation type bombs are painted on the head and base instead of with colored bands. Chemical and photoflash bombs are painted gray.

Marking

Bombs are marked with the following information: type, weight, model, filler and lot number. High explosive and drill bombs are

marked in black. Chemical bombs are identified by colored bands as follows: persistent gas by two bands; nonpersistent gas by one band; irritant gas by one red band; smoke by one yellow band; incendiary bombs by one purple band. Bomb bodies intended to be stored before loading are marked longitudinally with the word EMPTY in four equally spaced locations. When the bomb is filled, the word empty is painted over with the color of the bomb body. (Figure 7-2)

Fuzes are marked either by stenciling or stamping, with the type and model, lot number, and length of delay.

Primer detonators are marked with type and model, and length of delay. In addition the head of the primer detonator, M14, is painted to indicate the delay.

Packings which are intended to contain components of a complete round have the type and model of each component stenciled on the packing. The word "WITHOUT" is stenciled above this list until the components are packed, at which time the word "OUT" is painted over.

6. PACKING FOR SHIPMENT

In general, bombs are shipped unfuzed with the fuze holes closed with metal closing plugs. These plugs will not be removed except for inspection and for assembly of the complete round. Large bombs are shipped with two paper or metal shipping bands to protect the suspension lugs. The fin assemblies of such bombs are shipped separately in metal crates. Smaller bombs are shipped, finned, in metal crates. Small chemical and fragmentation bombs are packed in wooden boxes.

7. COMPLETE ROUND

Definition

A complete round consists of all the components and accessories necessary for the ammunition to function in the manner intended. Strictly speaking, complete round includes no more than the necessary number of each component. However, for purposes of supply, a complete round as issued may include both of the alternative components to allow for flexibility. For example, a complete round of

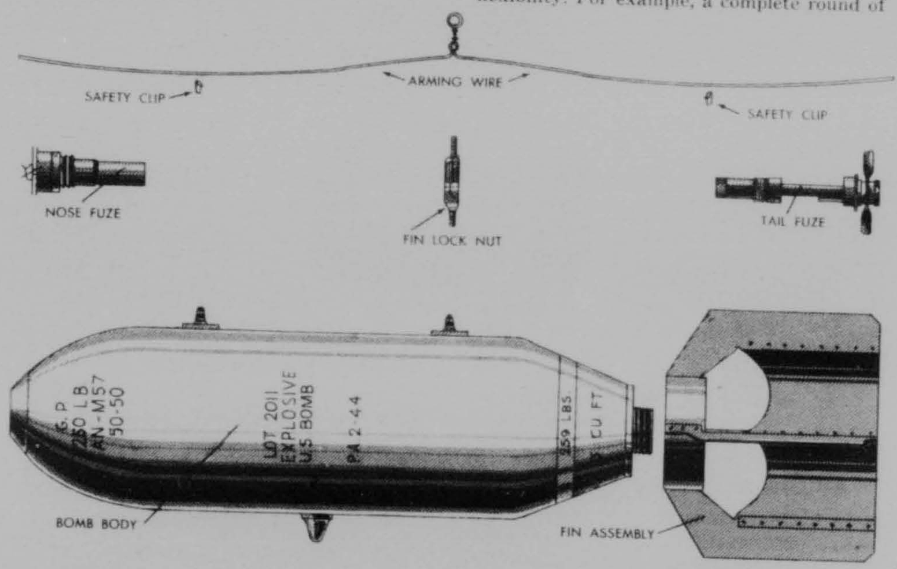


Figure 7—3. Complete Round Components.

THIS PAGE IS DECLASSIFIED IAW EO 13526

SERIES DEMOLITION BOMB

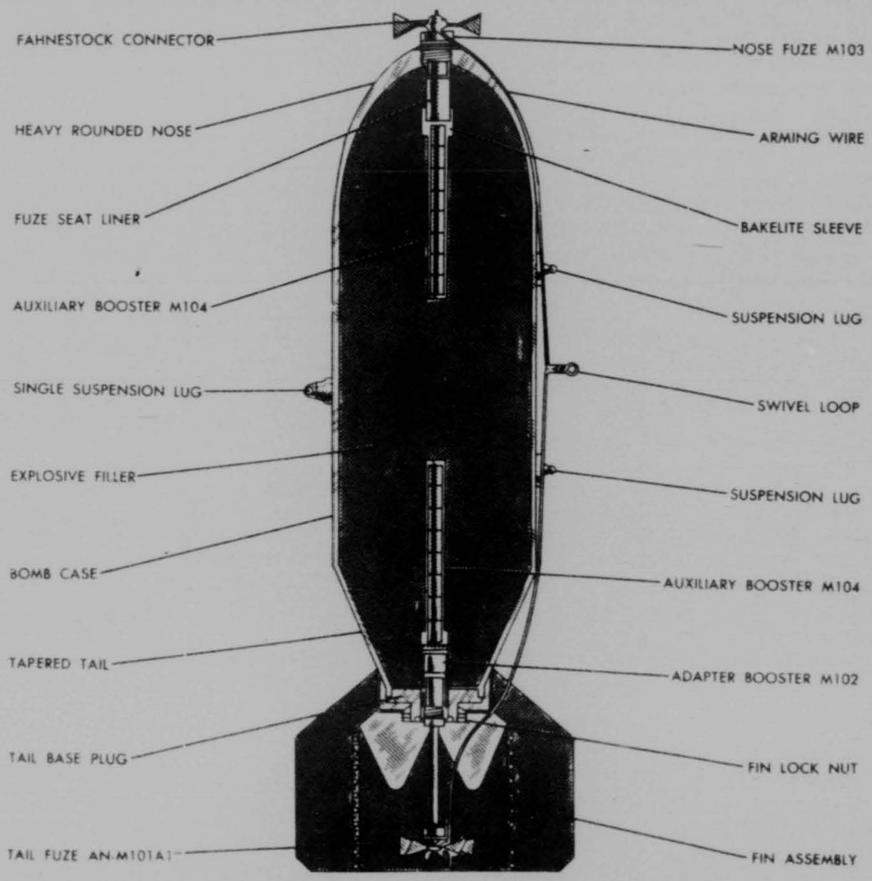

Figure 7–4. General Purpose Bomb, GP 500-Pound, AN-M43.

issue may include both a delay and a nondelay primer detonator, although only one will be used.

8. COMPONENTS OF COMPLETE ROUND AS ISSUED

In practice, it is necessary to separate various components of the complete round so that the careful handling required by one sensitive or frail component will not be necessary with an item as large and heavy as the assembled bomb. In general, the bomb is shipped in the following assemblies:

Bomb body containing explosive charge and auxiliary booster with suspension lugs attached and protected by shipping bands, and fuze cavities protected by plugs.

The fin, being light sheet metal, is shipped separately protected by a metal crate.

Fuzes contain the sensitive explosives and are given more careful handling. They are shipped separately so that if a fuse should accidentally explode, it cannot cause the explosion of the bomb.

Arming-wire assembly is shipped separately because it is small and is more easily packed separately or with smaller components than with the bomb body.

Exceptions to the general practice above will be given under the specific items as they are described in the following sections.

Percentage of Explosive

The relative amounts of explosive and metal in a bomb are dependent upon the use for which the bomb is designed.

Chemical Fillers

Chemical fillers, commonly known as chemical warfare agents, have been referred to as the weapons which "shoot around corners," due to their ability to filter through small crevices and to settle in all recesses thus seeking out their victims. History shows that chemicals as used in warfare were present in military activity as far back as 428 B.C., when, during a siege, wood was saturated with sulphur and pitch, burned under the wall of a city and produced checking poisonous gases. Chemical fillers have now become known as any substance which by its ordinary and direct chemical action produces a powerful physiological effect, a screening smoke, or an incendiary action. All of these agents are common fillers for aircraft bombs. A recent development in chemical fillers which was proven to be the most effective incendiary agent is the fire bomb. It is simply a fighter craft wing or auxiliary tank containing Quartermaster 72 Octane gasoline thickened with Napalm powder. The cheapness of manufacture, simplicity of assembly, spread, and intensity of the burning caused this bomb to be used extensively in areas where the enemy materiel was of a highly inflammable nature.

9. BOMB TYPES

General Purpose

The general-purpose bomb (Figure 7-4) is designed to meet the requirements of the great majority of bombing situations. The various models range in weight from 100 to 2000 pounds and the percentage of explosive in this type averages 50 per cent of the total loaded weight of the bomb. This proportion of filler weight to the total weight was selected so as to give a type of bomb which is suitable for general, all-around, aerial bombing of a great variety of targets. General-purpose bombs may be used for blast, fragmentation, or mining effect. They are adapted for (designed for use with) both nose and tail fuzes. Nose fuzes produce more efficient surface effect and tail fuzes produce more efficient deep (mining) effect. Both fuzes are generally used, the secondary fuze being used as insurance against malfunction. The general-purpose bomb has a cylindrical body which tapers in an ogive to the nose and in a straight cone to the base plug closing the tail end. It has two suspension lugs for double-hook suspension welded to the case on one side, and diametrically opposite, one lug for single suspension. Double-suspension lugs are spaced 14 inches apart on bombs weighing 1,000 pounds and less; they are spaced 30 inches apart on bombs weighing 2,000 pounds and more. The metal case is strong enough not to rupture on impact with heavy armor or high-strength, reinforced-concrete structures. General-purpose bombs are generally loaded with TNT or Comp B.

Light Case

The light-case, 4,000-pound bomb with a charge-weight ratio of 75 per cent is highly effective as a blast bomb for targets requiring no penetration. Since strength of case has been sacrificed to maximum charge, this type of bomb cannot be used for penetration. It must be fuzed to explode before the case breaks up on impact and therefore should be employed only on those targets against which surface blast is effective. In other respects this type resembles the general purpose described above.

Armor-piercing

Standard AP bombs are available in 1,000-pound and 1,600-pound sizes. This type of bomb is designed to pierce the heavy deck armor of modern battleships. The case is extremely heavy and as a consequence the percentage of explosive is about 15 per cent. In order to be effective, armor-piercing bombs must score direct hits. The effect of a near miss is small, due to the comparatively small amount of explosive. This type should not be used against unarmored or lightly armored ships because, being fuzed with a delay fuze to permit penetration of armor, the bomb would pass entirely through a light target before exploding. Armor-piercing bombs are streamlined in shape and adapted for tail fuze only. Suspension lugs are bolted to the body when the round is assembled for use. Early models used suspension bands with the lugs attached to the bands. Some armor-piercing bombs were made by converting armor-piercing shell, and average 5 per cent explosive. Armor-piercing bombs are loaded with explosive D.

Semi-armor-piercing

Standard SAP bombs are available in 500-pound and 1,000-pound sizes. This type resembles general-purpose bombs except that the bomb body is heavier and the explosive charge is approximately 30 per cent. It may be used against lightly-armored targets or, because of the heavy case providing better fragmentation, against concentration of personnel and materiel.

Depth

The depth bomb is a light-case type of bomb, designed for use against submarines, containing approximately 79 per cent of its total weight in explosive filler. The case is cylindrical and has a flat nose to reduce or prevent ricochet when dropped from planes flying at low altitudes. The depth bomb is fuzed with a hydrostatic fuze which functions at a predetermined depth rather than on impact. While a hydrostatic fuze may be of the nose or tail type, it is often designed for installation in a cavity running transversely through the body of the bomb. There is at the present time one depth bomb used by the Air Force. The weight of this bomb is 350 pounds. The explosive filler in this bomb is HBX. This explosive is composed of the following: 40 per cent RDX (research development explosive), 38 per cent TNT, 17 per cent aluminum powder, and 5 per cent desensitizer.

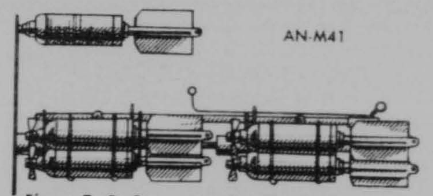

Figure 7—5. Fragmentation Cluster.

Fragmentation

Fragmentation bombs are designed to produce their effect through projection of the fragments of the body and are intended for use against personnel and light materiel. They are available in the following sizes:

M83, Butterfly	(4 lb. type), Wt. 4 lbs.
AN-M41A1, Frag	(20 lb. type), Wt. 20 lbs.
An-M40A1, Parafrag	(23 lb. type), Wt. 25 lbs.
M72A1, Parafrag	(23 lb. type), Wt. 24, 25 lbs.
M82 (T9), Frag	(90 lb. type), Wt. 86, 87 lbs.
M86 (T13), Parafrag	(110 lb. type), Wt. 118 lbs.
AN-M81 (T10), Frag	(260 lb. type), Wt. 261, 263 lbs.

Clusters are available in 100-pound and 500-pound types:

100 lb. cluster:	
M28, (24 4 lb. M83s)	Wt. 155 lbs.
M4A2, (3 23 lb. Parafrags)	Wt. 87 lbs.
M1A1, (6 20 lb. Frags)	Wt. 125 lbs.
500 lb. cluster:	
M26 (T4), (20 20 lb. M41s)	Wt. 583 lbs.
M27 (T8), (6 90 lb. M82s)	Wt. 590 lbs.
M29, (90 4 lb. M83s)	Wt. 415 lbs.

When employed in sufficient numbers to cover large areas, either from high altitudes as clusters of stabilized bombs, or from minimum altitudes with parachutes, fragmentation bombs will effectively damage light materiel targets such as radar equipment and antennas, aircraft, vehicles, antiaircraft, light artillery, mortars, and machine guns, and will produce extensive casualties to exposed personnel. Although present information is inadequate, it is believed that the 260-pound fragmentation bomb will be effective against heavier materiel. Tests are now underway to determine the relative effectiveness of the 90-pound and 260-pound fragmentation bombs. Where aircraft or light material targets are protected from lateral damage by revetments, the greater quantity and dispersion of the 20-pound fragmentation bomb and the possibilities of carpeting the entire target area render the use of this bomb preferable to other types of fragmentation bombs. The M28 cluster of twenty-four bombs and the M29 cluster of ninety bombs are considered to be highly effective against personnel within a radius of twenty feet. The explosive charge of the fragmentation type averages 14 per cent. The body walls are of uniform thickness and may be made up of steel coils, while the armor-piercing bomb which also may be a 14 per cent bomb, has the weight and thickness of metal concentrated toward the nose. One type of fragmentation bomb is stabilized by fins. The other, designed for low-altitude bombing, is equipped with a parachute to delay the impact of the bomb until the airplane has cleared the danger area. Some bombs can be fuzed in various ways designed to function on or above the surface of the ground. One fuzing allows the bomb to burst approximately five seconds after the cluster opens or on impact with the ground, depending on the setting. A second fuzing provides a mechanical time setting which detonates the bomb in from five to thirty minutes after arming. A third, the anti-disturbance fuze, becomes fully armed approximately two seconds after impact and will detonate the bomb when slightly disturbed at any time thereafter. Fragmentation bombs are usually loaded with TNT or Comp. B.

Chemical Bombs

Gas and smoke have a light metal case which acts only as a container for the chemical agent up to the time the bomb strikes the ground. These bombs are equipped with superquick fuzes because any penetration of the bomb would carry the chemical agent under ground, wasting the charge. The bomb case is opened and the charge scattered by a burster which is an explosive element resembling the booster and auxiliary booster of explosive bombs. Some bursters are long tubes of explosive which are located along the axis of the bomb.

Incendiary bombs are of two types; one has a case similar to the gas and smoke bombs and is loaded with a charge of inflammable material such as oil; the other type has a heavy magnesium alloy case containing an igniting charge and the case itself acts as the main charge of the bomb.

Photoflash Bombs

This type is a pyrotechnic item but is classed with bombs because of its explosive effect. It is a light case bomb with a charge of flashlight powder instead of high explosive.

Practice

This type of bomb is provided for target practice. There is a wide range of types and weights in order to represent all types of service bombs. Some practice bombs have a fuze and a spotting charge; others are completely inert. Some are sand loaded to weight at point of use, others are constructed to weight. Each model is described in the following section.

Drill Bombs

Completely inert bombs and components are supplied for the training, and practice of ground crews. Each type and weight of service bomb is represented by a corresponding drill bomb. Drill bombs are made up from the metal parts of service bombs, inert loaded when necessary. They are used for practice fuzing, unfuzing, and handling. Drill bombs, unlike inert practice bombs, are not expendable; they are not to be used for bombing practice.

Gauge Bombs

Completely inert bombs are furnished to the Air Force by the Ordnance Department for use in gauging and testing aircraft. Such bombs are not issued to the field.

10. COMPONENTS—BOMBS

Complete Round

The components of a complete round are, in general, as follows (Figure 7-3):

Bomb, unfuzed, w o fin. This is composed of bomb body with explosive charge and auxiliary booster, fuze-seat liner, base plug with fin-lock nut and adapter-booster, suspension bands (when lugs are not attached directly to bomb body), shipping bands or packing crate, and nose and tail closing.

Nose fuze (not included in AP bombs).

Tail fuze (not included in small chemical or small fragmentation bombs).

Fin assembly (attached to bomb in smaller sizes).

Arming wire assembly.

Trunnion band (for dive bombing only).

Bomb Body

Fuze-seat Liner. The fuze-seat liner is a metal cap which is assembled inside the nose of the bomb to keep a cavity clear for assembling the nose fuze.

Base Plug. The base plug closes the filling hole and forms the base of the bomb. The tail fuze adapter-booster is screwed into the base plug. An extension of the plug to the rear is threaded to provide for attachment of the fin assembly by means of the fin-lock nut. For shipping, the fin-lock nut is covered by a fiber protector and is wired in place. In bombs of current manufacture the base plug has studs extending into the explosion charge to prevent removal of the plug.

Adapter-booster. An adapter is a bushing threaded on the outside for assembly to the bomb body and on the inside for assembly of the fuze. When the booster is assembled to the adapter, the assembly is known as an adapter-booster. Tail adapter-boosters of high explosion and chemical bombs are drilled for the insertion of lock pins to prevent their removal.

Suspension Bands. When, for any reason, it is inadvisable to weld or bolt suspension lugs to the bomb body, the lugs are attached to metal bands which are bolted around the bomb body. When suspension bands are to be installed, their position is indicated by a band painted on the bomb.

Shipping Bands. Shipping bands are attached to the bomb to protect the suspension lugs. They may be compressed paper with a recess for the lugs or may be of metal in the form of a U-shaped channel. They are not removed until the bomb is prepared for use.

Closing Plugs. The openings to the fuze cavities are closed during shipping and storage by metal plugs. Those plugs serve to protect the fuze-seat cavity and threads. They may be removed only for inspection or for fuzing the bomb. If a bomb is returned to storage after being prepared for use, the fuzes are removed and the fuze hole plugs replaced.

Fin Assembly. The fin assembly provides for stability of the bomb in flight. Some bombs of one hundred pounds and smaller size have the fin assembled to the bomb body before shipment. Larger bombs are shipped with fin unassembled. In such cases the fin assembly is packed in a metal crate. The fin assembly consists of a fin sleeve which fits over the tail of the bomb and is held in place by the fin-lock nut. The sheet-metal fin blades are riveted or spot welded to the fin sleeve and, with the supporting members, forms a square box. Fins should be protected against bending or other distortion because such distortion materially alters the flight of the bomb.

Trunnion Bands. When trunnion mounting is desired for dive bombers, the trunnions are mounted on a steel band which is bolted to the bomb body in the same manner as suspension bands. The center of gravity band or the single suspension lug serves to indicate the proper location of the trunnion band. AP bombs are drilled and threaded so that the trunnions may be screwed into the bomb body.

SECTION II—FUZES

1. GENERAL

A fuze is a mechanical device designated to initiate a detonation under the circumstances desired. Fuzes are classified according to position as nose, tail, and transverse, and according to function as time, impact, and hydrostatic. Time fuzes function a predetermined number of seconds after the arming pin is released; impact fuzes function after the bomb strikes a resistant material; and hydrostatic fuzes function by water pressure. Impact fuzes are classified as delay when they are designed to have a definite time between impact and explosion of the bomb, and as superquick (nose) or nondelay (tail) when there is no delay element incorporated.

Arming

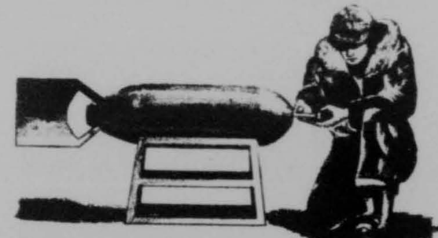
Bomb fuzes are shipped in a safe condition. They are so constructed that, while they are unarmed, they cannot function. A detonator safe fuze is one in which the detonator is out of line with the firing pin until the fuze arms.

Nose Fuzes

Nose fuzes generally are held unarmed by the presence of safety blocks between the striker and the fuze body thus preventing the firing pin from being driven into the primer. (Figure 7-6)

Tail Fuzes

Tail fuzes, in general, are held unarmed by an arming item being screwed into the inertia type of firing pin. The booster is not assembled to the fuze in this case; it is located in the adapter-booster assembled to the bomb.



"Fuzing a Bomb"

2. CLASSIFICATION OF FUZES

Position

Fuzes are classified according to the position in which they are assembled to the bomb as nose, tail and transverse.

Arming

Fuzes are classified according to method of arming as arming-pin type and arming-vane type. These are further classified as:

Direct Arming. When the fuze becomes armed immediately on the ejection of the arming pin or by direct unscrewing of the arming stem by the vane.

Delayed Arming. When the ejection of the arming pin initiates a powder train or clock-like mechanism which arms the fuze after a predetermined time or when the arming vane is connected to the arming stem by a reduction-gear assembly.

Action

Fuzes are classified according to action as time, impact, and hydrostatic.

Time fuzes function to explode the bomb a certain number of seconds after release. Time fuzes act in a manner similar to an ordinary alarm clock.

Hydrostatic Fuzes

This type works on the principle of a bellows or diaphragm working against a spring of fixed strength. When the external pressure overcomes the resistance of the spring the firing pin is released and driven against the primer by spring action. In some fuzes, provision is made for adjustment by a mechanism controlling the compression of the diaphragm spring. This is set by an external lever. In other fuzes, adjustment is obtained by interchanging the spring.

Primer Detonators

In order to allow variation of the delay action of tail fuzes, primer, delay element, and

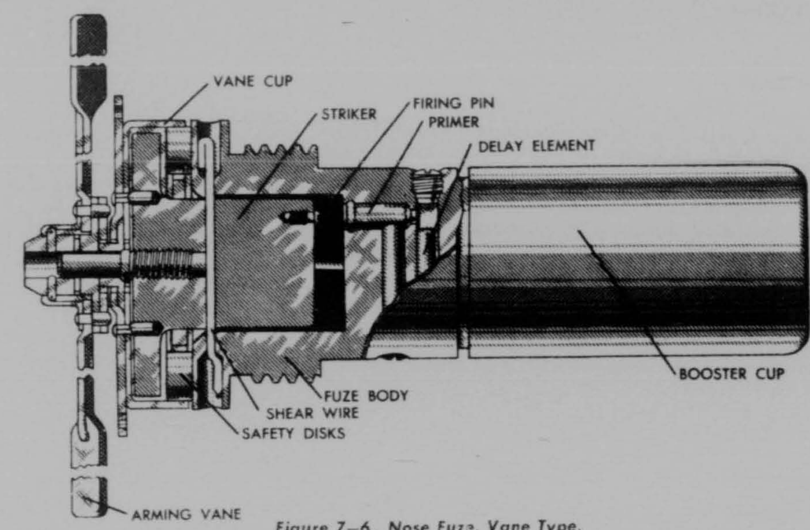


Figure 7—6. Nose Fuze, Vane Type.

detonator are assembled in one interchangeable unit. Primer detonators of various delay times are supplied. Primer detonator, M14 is supplied with 0.1 second delay, 0.025 second delay, 0.01 second delay and non-delay. Primer detonator M16 and M16A1, are supplied with 8 to 15 second delay and 4 to 5 seconds delay.

Arming Vane

In general, vane types of fuzes are packed and shipped with the arming vane removed. The vane assembly is packed separately and shipped in the same box.

3. IDENTIFICATION OF FUZES

Fuzes are identified by the information marked on the containers and stamped on the fuze body. They may be identified by inspection as herein described. Detailed differences are as follows: Rapid-arming tail fuzes are distinguished from slow-arming types by the rod which extends from the arming head forward along the arming stem for approximately 1.5 inches. This rod is present on the slower-arming types and absent from the rapid type. Fuzes of one series (that is, fuzes with the same mechanism and action, but designed for bombs of different sizes) are distinguished among themselves by the length of the arming stem. Special-purpose fuzes such as hydrostatic have a distinctive appearance and method of operation. They are described in the following sections.

4. FUZE EXTENSION

The most efficient use of fragmentation and chemical bombs requires that they detonate at or slightly above the surface of the ground. The nose fuze extension consists of a steel tube, filled with tetrytol, adapted to receive the fuze and screw into the fuze seat of the bomb.

5. NOSE ADAPTER-BOOSTER

Large bombs are adapted for large-diameter nose fuzes. An adapter-booster which is threaded externally to fit the large fuze seat and internally to receive the smaller fuze is necessary in order to use smaller special-purpose fuzes with these bombs.

6. PRECAUTIONS

Fuzes are packed in sealed moisture-proof containers. They must not be unsealed until

required for use; fuzes unpacked for use and not used are resealed and returned to their original packings which must be effectively sealed with tape.

Fuzes must be protected from excessive heat.

Fuzes must be handled with care at all times. Boxes should not be dropped, tumbled, dragged, or thrown; nor may they be struck with a hammer or similar tool either to open the box or align in a stack.

Fuzes should not be unpacked or packed within one hundred feet of a magazine containing explosives.

When the fuze is unpacked it should be examined to insure that shipping seals are intact, that safety blocks or arming pins are in place and that the arming stem is not unscrewed.

Safety cotter pins, shipping wires, and seals must be left in place until the arming wire is assembled to the fuze.

Care should be exercised not to bend or distort vane assemblies.

Only primer detonators authorized for use with the particular fuze may be used.

When an authorized alteration is made to a fuze, the fuze must be so marked as to indicate clearly the nature of the modification. (For example, when the depth setting of a hydrostatic fuze is changed, the new depth setting is stenciled on the pistol head.) If the fuze is repacked after alteration, the container also must be marked.

Fuzes may not be disassembled further than authorized without prior approval of the Chief of Ordnance.

7. NOSE FUZES

General

Only one of the various nose fuzes will be discussed in detail in this text. For further information on other types the various Army publications may be consulted.

Fuze, Bomb, AN-M103 (Nose)

Data. Fuze, bomb, AN-M103 (nose) is a detonator-safe, arming-vane type of nose fuze which requires 230 revolutions of the vane to arm for delay action and 345 revolutions to arm for instantaneous action. It is designed to detonate the bomb on impact, either instantaneously, or with 0.1 second delay, dependent upon the setting of a delay pin. The fuze has an overall length of 7.1 inches, and weighs 3.7 pounds. Fuze, bomb, AN-M103 (nose), is authorized for use in all G.P., demolition, and S.A.P. bombs when the tail fuze used has a delay of 0.1 second or less. It may also be used in depth bombs (except AN-Mk. 17) and G.P. bombs with hydrostatic fuzes, but only if selective arming racks are available. Fuze, bomb, M103 (nose) is an earlier model which differs from AN-M103 in requiring 785 revolutions of the vane to arm the fuze. In other respects, information given herein concerning the AN-M103 applies equally to the M103.

Description. Fuze, bomb, AN-M103 (nose) is cylindrical in shape. (See Figure 7-7.) The inner portion which assembles inside the fuze seat in the bomb is 5 inches in length and 1 3/4 inches in diameter. The outer portion is 1 1/4 inches long and 2 1/2 inches in diameter. The arming-vane hub projects 3/4 of an inch from the outer end. The two-blade arming vane is shipped separately. A vane stop which consists of two straps attached to the vane hub and fuze top respectively, is fastened during shipping and handling by a safety cotter pin and a sealed shipping wire. On the side of the fuze, there are two diametrically-opposed lugs which serve to prevent the hand slipping when fuzing or unfuzing the bomb. The setting pin is located on the circumference midway between the lugs. On the setting pin, there is a cross member which forms a key and rests in one of two slots in the pin seat; when the key is in the deep slot the fuze is set for delay and when the key is in the shallow slot, the fuze is set for superquick action.

Function. The fuze contains four interrelated systems, arming, delay-selecting, firing, and the explosive train.

The arming system consists of the arming vane (90 degrees out of position in illustration), vane cup, reduction gears, arming screw, and safety blocks. The arming vane, reduction gears, and arming screw are assembled in one unit with the vane cup; the safety

THIS PAGE IS DECLASSIFIED IAW EO 13526

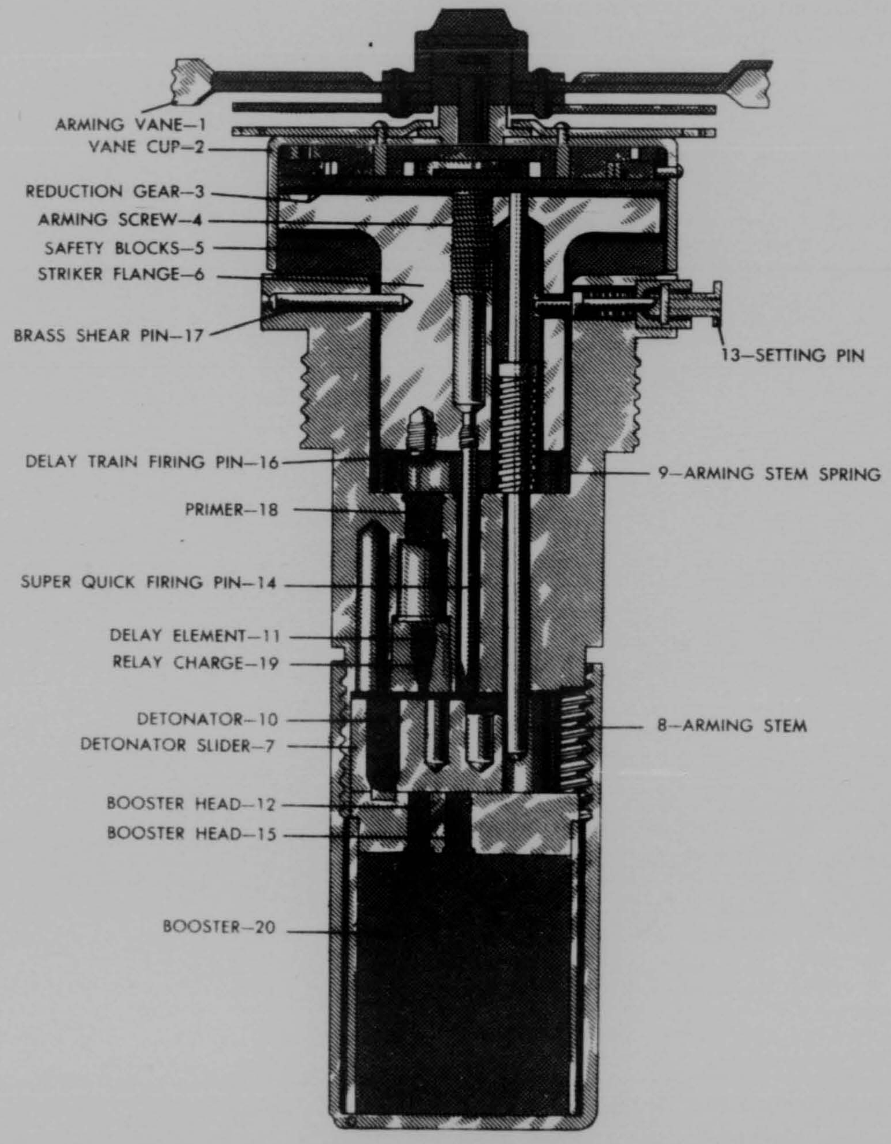

Figure 7–7. Fuze, Bomb, AN-M103 (Nose) Unarmed.

blocks are held between the flange of the striker and the fuze body by the vane cup. When the arming vane is rotated by the air stream, the arming screw unscrews from the striker body carrying the vane, gears, and vane cup with it. When the vane cup has progressed ¼ inch the safety blocks are released. Positive ejection is insured by a flat spring assembled within the circle of blocks. The arming vane continues to rotate until the arming screw has progressed ½ inch. Then the entire assembly becomes disengaged from the fuze and falls free.

The delay-selecting system consists of the detonator slider which is held in place by the arming assembly. As the arming screw advances, the arming stem follows, driven by its spring. When the stem has progressed ¼ inch, it clears the first step of the detonator slider which moves to line up the detonator with the delay element and booster lead of the explosive train. If the setting pin is in the delay position, it restrains the arming stem from moving further and, on impact, the fuze functions with 0.1 second delay. If the pin is set for superquick action, the arming stem continues to progress until the end of the stem clears the second step of the detonator slider and the slider moves to line up the detonator with the superquick firing pin and booster lead. Upon impact, the fuze will function immediately. The detonator is out of line with the other explosive elements until the fuze arms; the fuze is detonator safe.

Note: Once the fuze arms, detonator slider cannot return to its original position.

The firing system consists of a cylindrical striker and two firing pins, one for the delay train, the other for the superquick train. A flange at the outer end of the striker forms, with the fuze body, a groove which contains the safety blocks. The striker is held in place after arming by a brass shear pin and the setting pin which acts as an additional shear pin. Upon impact, after arming, the striker is driven inward shearing the pins and driving both firing pins with it.

The explosive train consists of a primer, delay element, relay charge, detonator, booster leads, and booster. The primer, delay element, and relay charge are housed in the fuze body in position to be initiated by impact of the delay firing pin. The detonator is assembled in the detonator slider and the booster is assembled to the inner end of the fuze. When the slider is set for superquick action, the superquick firing pin is driven directly into the detonator, thus serving as its own primer. The primer, delay charge, and relay charge, although fired by the delay firing pin, are bypassed, and the booster is detonated immediately.

Preparation for Use. Aside from assembling the vane to the vane hub (described below) the only preparation of the fuze necessary is the change of delay setting. This is done by pulling the setting pin out until the key clears the setting slots, turning the pin a quarter turn so that the key clears the setting slots, turning the pin a quarter turn so that the key will enter the outer slot, and letting the pin drop back. As shipped, the pin is set in the deep (delay) slot. It needs to be changed to the shallow (superquick) slot only when detonation of the bomb above ground is desired.

Fuzing and Unfuzing. Fuze, bomb, AN-M103 (nose) (Figure 7-8) is assembled to the bomb in the steps described below:

The container is unsealed and the fuze is removed from the packing.

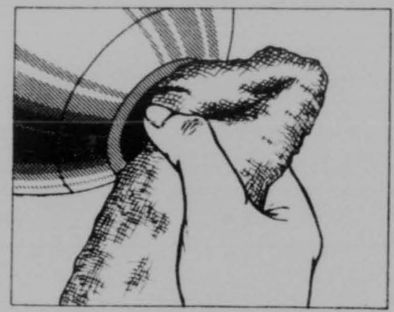
The fuze is inspected to see that it is serviceable and to see that the setting is for superquick or delay action as desired (If the fuze is set SQ and not used, it should be reset to delay on repacking).

The seal wire is cut and removed.

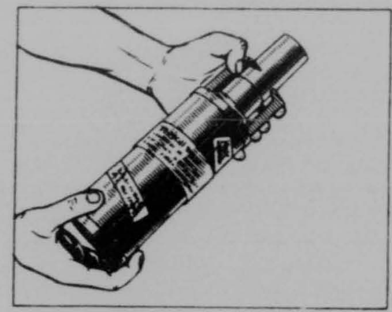
The fuze, less vane, is screwed into the bomb handtight. The use of a wrench or other tool is neither necessary nor permitted.

The arming wire is uncoiled; the shorter branch is threaded first through the forward suspension lug of the bomb, then through the upper pair of eyelets in the vane stop straps. If the nearer pair is occupied by the cotter pin, another cotter pin is placed in the opposite eyelet; then the original cotter pin is removed and replaced with the arming wire.

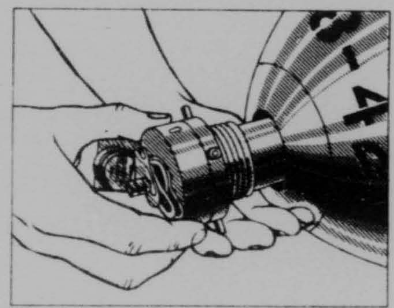
THIS PAGE IS DECLASSIFIED IAW EO 13526



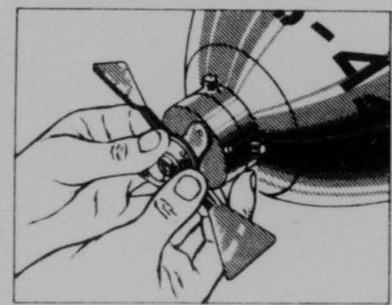
(1) AFTER REMOVING NOSE PLUG, INSPECT THREADS AND WIPE OUT ANY GREASE AND DIRT



(2) REMOVE FUZE FROM SEALED CONTAINER (IMPORTANT—KEEP THE CONTAINER IN EVENT FUZE HAS TO BE REPACKED)



(3) SCREW FUZE IN PLACE HANDTIGHT. ALWAYS CUP HAND TO GUIDE FUZE AND TO GUARD AGAINST DROPPING. A HARD BUMP CAN EXPLODE DETONATOR. NEVER TIGHTEN WITH WRENCH OR OTHER TOOL UNLESS SPECIFICALLY AUTHORIZED.



(4) PUT VANE IN PLACE BY PRESSING CENTER BUSHING. THIS AVOIDS POSSIBLE DISTORTION OF BLADES.

(5) THREAD ARMING WIRE THROUGH UPPER EYELETS. ATTACH SAFETY CLIP (A). ALLOW ARMING WIRE TO EXTEND 2½ TO 3 INCHES.
ARMING WIRE MUST BE FREE OF KINKS AND BURRS

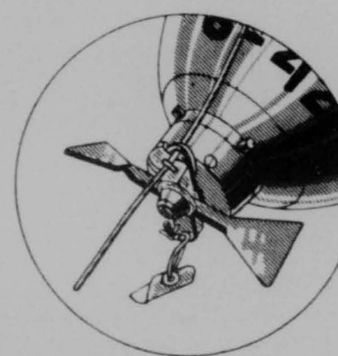


Figure 7–8. Fuzing.

The arming wire is adjusted to protrude 2 to 3 inches beyond the vane stop. One safety clip is slipped over the end of the arming wire and moved up until it just touches the face of the strap. It is important that the protruding section of wire is neither kinked nor burred.

The arming vane assembly is slipped over the vane hub so that the locating pins on the vane enter the corresponding holes in the vane hub and the vane holder spring snaps into the groove in the hub.

Note: The assembly of tail fuze and fin assembly may precede or follow the installation of nose fuze described above.

Upon completion of assembly of the round, the cotter pin and tag are removed from the vane stop.

If a bomb is not dropped it must be unfuzed and returned to storage, reversing the steps specified above.

Accidental Arming. If a fuze should be found with the vane cup advanced enough to have released the safety disks, it is armed and will function on receiving a blow or pressure on the striker. In such a case the first action taken will be to place improvised safety blocks between the flange of the striker and the fuze body and taping or otherwise fastening them in place. The improvised blocks should be of a material thick enough to take up all available space between the flange and fuze body. After the blocks are in place the fuze may be handled in comparative safety. No further attempt will be made to disarm such a fuze. It should be destroyed as unserviceable ammunition in a dangerous condition.

Partial Arming. The earlier model of this fuze, fuze, bomb, M103 (nose), may not arm before impact when released from minimum altitudes for over-water bombing. When such use is contemplated the older type fuze may be partially armed by removing the safety pin and seal wire and turning the vane hub counterclockwise for approximately 250 revolutions, until exactly $\frac{1}{8}$ inch of the thickness of the safety disks is uncovered by the vane cup. It should be noted that no more than $\frac{1}{8}$ inch of the disks should be exposed and not more than 250 turns of the vane hub be made. The seal wire and safety pin must be replaced, and the tags attached to both must be marked to show that the fuze is partially armed. If partial arming is done in advance of requirements, fuze containers will be marked. Fuze, bomb, M103 (nose), partially armed, as described above, may be employed on any mission without restoration to its original condition. Fuze, bomb, AN-M103 (nose), normally arms within minimum combat altitudes; it will not be partially armed.

Marking. The container in which the fuze is packed is marked with the nomenclature of the fuze, the ammunition lot number, the fuze assembly drawing number, and the date of its revision. The fuze has stamped in the metal of the body the type, model, and lot number. Two instruction tags are attached to the fuze as shipped. One attached to the seal wire, reads: "Remove this seal before assembling vane to fuze"; the other, attached to the safety pin, reads: "To be removed after bomb has been placed in dropping gear, arming wiring inserted. If bomb is not dropped, replace pin before removing arming wire."

Packing. The fuze, less vane, is packed in an individual, sealed, metal container. When packed in bulk, 25 such containers and vanes, mounted on spindles, are shipped in one package.

Extension Fuze, M1, Varied Lengths

This fuze may be used in any bomb adapted for the AN-M103 nose fuze. It consists of a burster support and a burster assembly. The burster support is a steel tube of 2.375 inches outside diameter which has a male thread at one end and a female thread at the other. The former screws into the adapter in the nose of the bomb; the latter receives the AN-M103 nose fuze. The burster assembly consists of an asphalt-impregnated, chipboard tube which has a recessed metal cap crimped to one end and a plain metal cap cemented to the other. The tube is filled with cast tetrytol. A shakeproof lock washer is supplied with each assembly. The various sizes of the components are as follows: Length, Overall (ins.)

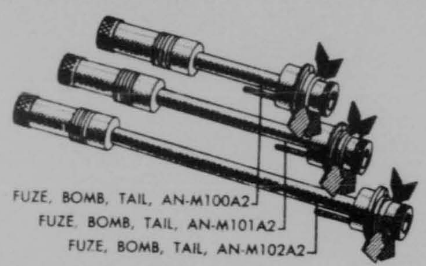

Figure 7–9. Tail Fuze Series.

Nomenclature	Burster Support	Burster Assembly
Extension, fuze, M1, 6-in.	6.72	5.92
Extension, fuze, M1, 9-in.	9.72	8.92
Extension, fuze, M1, 12-in.	12.72	11.92
Extension, fuze, M1, 18-in.	18.72	17.92
Extension, fuze, M1, 24-in.	24.72	23.92
Extension, fuze, M1, 30-in.	30.72	29.92
Extension, fuze, M1, 36-in.	36.72	35.92

Fuze, Bomb AN-M103A1 (Nose)

The later model of the AN-M103 is the AN-M103A1. The only difference between these two fuzes is a slight modification in the arming screw which has been lengthened to overlap the collar of the arming stem on the AN-M103A1. This modification was necessary because of the many accidents that were happening in crash landings.

To assemble the extension the procedure is as follows:

The arming wire must be of adequate length to reach the increased distance to the fuze.

Components are removed from their packing and inspected to be sure they are in good condition and match in size.

The fuze-hole plug of the bomb is removed and inspected.

The lock washer is placed on the booster support and the support is screwed into the nose fuze adapter. It must be tight enough for the lock washer to take hold.

The burster is inserted, crimped end first, into the support and pushed in as far as possible. It should not be forced. If the burster binds, one inspects to see whether the support or the burster is at fault and the faulty item is discarded.

The fuze is assembled in the outer end of the extension as described above.

If not used, it is returned to original condition and packing.

Extension fuze, M1, should be painted olive drab, and marked in black.

8. TAIL FUZES

Fuze, Bomb, AN-M100A2 (Tail)

Data. Fuze, bomb, AN-M100A2 (tail) (Figure 7-9) is a vane type of tail fuze which arms after 175 revolutions of the arming vane and acts to detonate the bomb on impact with a delay determined by the primer detonator used. Figure 7-10. As issued, primer detonator, M14, 0.025 second delay is assembled to the fuze This may be replaced in the field by primer detonator, M14 of 0.1 second delay, 0.01 second delay, or nondelay. The fuze is approximately 9 inches long and weighs 2.7 pounds. It is authorized for use in general-purpose and fragmentation bombs of 100 to 300 pounds. Earlier models differ as follows: Fuze, bomb, M100A1 and AN-M100A1 require 675 revolutions of the arming vane to arm the fuze. Fuze, bomb, M100 had a 0.1 second delay primer detonator permanently assembled to the fuze as well as the longer arming. All earlier types had an 8-blade vane. If earlier models are used in low altitude over water bombing, they should be partially armed as described below.

Description. Figure 7-11. Fuze, AN-M100A2 (tail) consists of body, stem, and arming head.

The body is cylindrical and is threaded to screw into the adapter of the bomb. A primer detonator, M14, is screwed into the inner end; the stem is assembled to the outer end. The body contains an inertia type of firing pin and

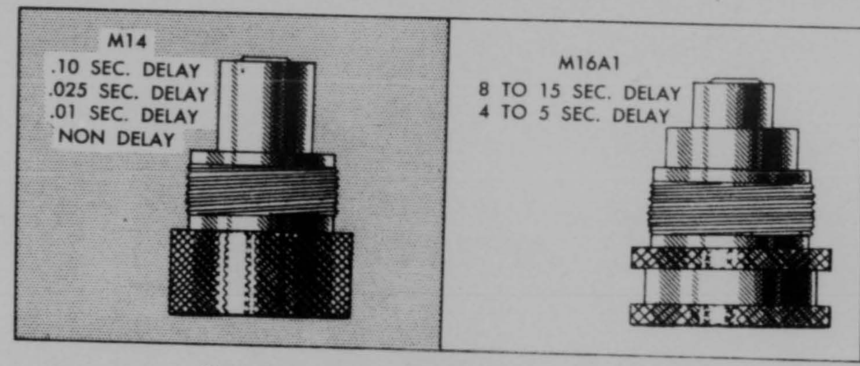

Figure 7–10. Short and Long Delay Primer Detonator.

its restraining spring. A cotter pin is placed through the body and firing pin for shipping.

The stem tube connects the body and the arming-head cup. The inner end of the arming stem is screwed through the body and into the firing-pin plunger; the arming mechanism is attached to the outer end by means of a cotter pin.

The arming head contains the arming-vane assembly and reduction-gear train. A stop rod passes through the cup and extends toward the body parallel to the stem. The arming vane is a 4-blade type and is packed separately. A safety pin is sealed into a vane stop for safety in handling.

Function. When the arming wire is withdrawn, the air steam turns the arming vane which turns the bearing-cup assembly. A pinion, mounted on the bearing cup, is in mesh with a 29-tooth fixed gear and a 30-tooth movable gear. The fixed gear is prevented from rotating by the stop rod passing through the stem cup. Each revolution of the pinion with the vane forces the movable gear one tooth 1/30 revolution ahead of the fixed gear. The fixed gear is connected to the arming stem by a cotter pin passing through the gear carrier and the arming stem. As the arming stem rotates, it unscrews from the firing-pin plunger. After 5.7 revolutions of the arming stem (approximately 175 revolutions of the vane) the stem clears the plunger and the fuze is armed.

Note: There is no external evidence that the fuze is armed other than the progress of the arming head out of the cup, shortening the amount of stop rod exposed by .6 inch. The vane assembly is still attached to the fuze. After about 200 more revolutions of the vane, the stem unscrews from the fuze body and vane; arming head and stem assembly are carried clear of the fuze by the air steam. Upon impact, the plunger is driven forward and the firing pin strikes the primer. The flame from the exploding primer ignites the delay charge which burns the required time and ignites the relay charge. This explodes the detonator.

Preparation for Use. When removed from the packing, the fuze is ready for use except for assembly of the arming vane, described below, and for possible change of the primer detonator. When a delay other than 0.025 second is required, the primer detonator is unscrewed by hand. The use of tools is neither necessary nor permitted. A primer detonator, M14 of the desired delay is removed from its packing and inspected. It is screwed hand-tight into the base of the fuze. The primer detonator removed from the fuze in the packings of the substitute is sealed and marked to indicate the delay. If the plunger spring or spring washer fall out of the fuze when the primer detonator is removed, they should be replaced before the new primer detonator is assembled.

THIS PAGE IS DECLASSIFIED IAW EO 13526

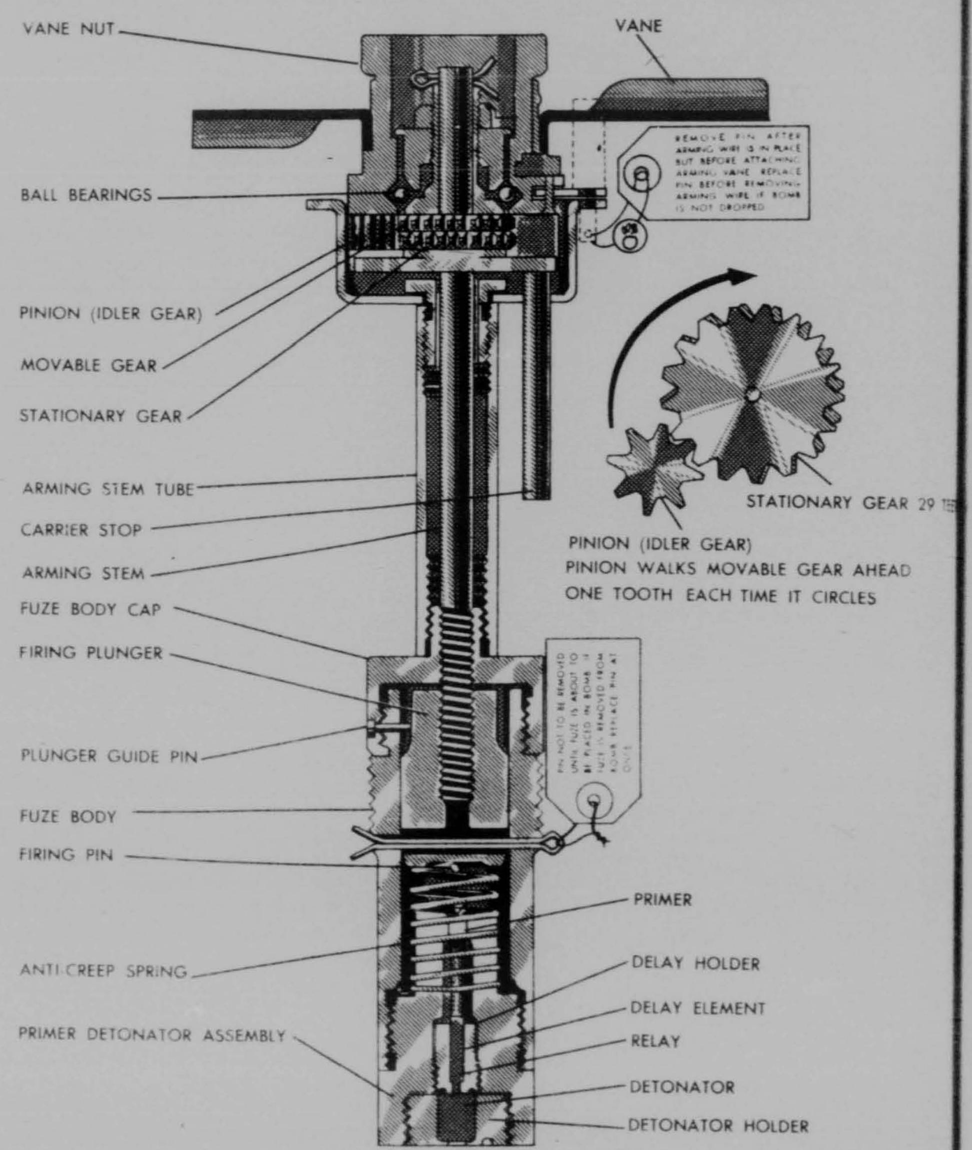

Figure 7–11. Fuze, Bomb, AN-M100A2 (Tail).

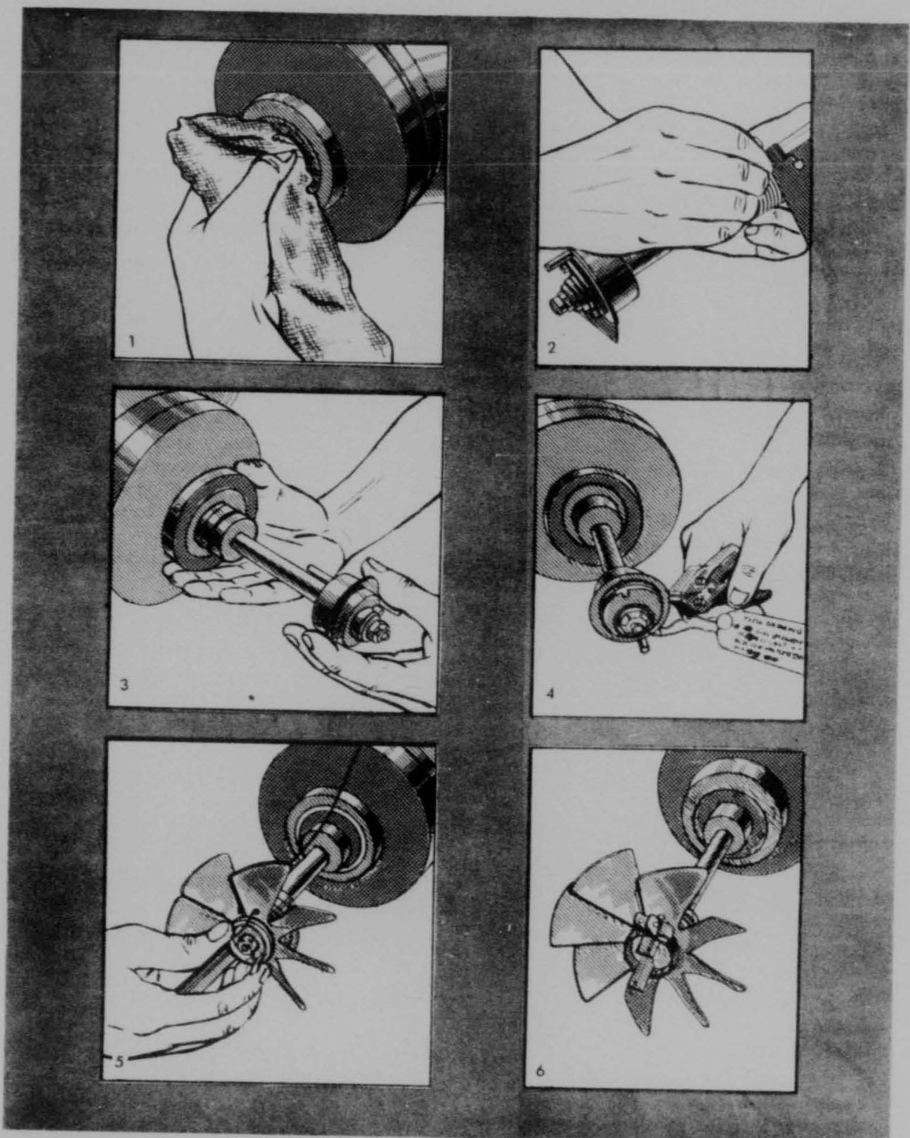

Figure 7–12. Fuzing (Tail).

THIS PAGE IS DECLASSIFIED IAW EO 13526

Caution: Primer detonator, M14, used in this fuze and primer detonator, M16, used in other fuzes are not interchangeable. An attempt to assemble a primer detonator to a fuze for which it is not designed will ruin both fuze and primer detonator. Primer detonators may be distinguished by the knurling around the base. The M14 has a single wide band; the M16 has two narrow bands.

Fuzing. Figure 7-12. In fuzing the bomb with fuze, bomb, AN-M100A-2 (tail), the following sequence is to be observed:

The can is unsealed and fuze removed from its packings.

Fuze is inspected for serviceability and for presence of primer detonator of desired delay.

Cotter pin which passes through body of fuze is removed.

Fuze is screwed into adapter-booster handtight.

Long branch of arming wire is threaded through rear suspension lug of bomb, then through eyelets of vane stop. If nearer eyelets of the vane stop are occupied by the safety pin, the safety pin from the fuze body is placed in opposite vane stop. The seal wire is then cut, the pin removed and the arming wire inserted.

Safety pin is removed.

The wire is threaded through hole in arming vane and vane is assembled to arming head and vane nut is screwed down handtight. Slots in vane hub must be properly located over studs.

Arming wire is adjusted to protrude two to three inches. All kinks and burrs are removed.

The safety clip is placed on the wire and moved up until it just touches the face of the vane.

If the bomb is not used, it is unfuzed and returned to storage reversing the steps listed above.

Explanation of Figure 7-12.

After removing tail plug, one wipes threads carefully, and attaches fin assembly.

One removes cotter pin in the fuze body. (Most fuzes cannot be inserted with this pin in place. Some fuzes have several pins; some none.)

Fuze is screwed into place, holding other hand below to guard against dropping or bumping detonator against bomb body. One should screw in handtight and never tighten with wrench or any other tool unless specifically directed to do so.

Car seal is removed from outer end of fuze.

Arming wire is threaded into place and put on vane.

Safety clip is put in position just touching vane. Excess arming wire is cut off so as to allow only 2½ to 3 inches to extend. It must be free of kinks and burrs.

Accidental Arming. Should this fuze become armed accidentally, as shown by the progression of the arming head and shortening of the stop rod as described above, the fuze will have first the vane assembly and then the primer detonator removed. The fuze may then be disarmed by authorized and experienced personnel as follows:

Cotter pin is placed through body of fuze.

The cotter pin is removed at the outer end of the arming stem which holds arming head on stem. Arming assembly is removed.

If there is a register hole through the stem tube and stem, arming stem is screwed into plunger until holes in the stem and stem tube are in register. A cotter pin is placed through these holes. If there is no register hole, stem is screwed down tight then backed off on turn.

Arming head is replaced on stem and cotter pin is replaced.

If used, cotter pin in stem is removed.

Primer detonator is replaced.

Partial Arming.

Fuze, bomb, AN-M100A2 (tail) will arm within the minimum combat altitudes; hence, partial arming is neither required nor permitted.

Fuze, bomb, AN-M100A1 or M100 may be partially armed as follows if the bomb is to be carried on internal racks:

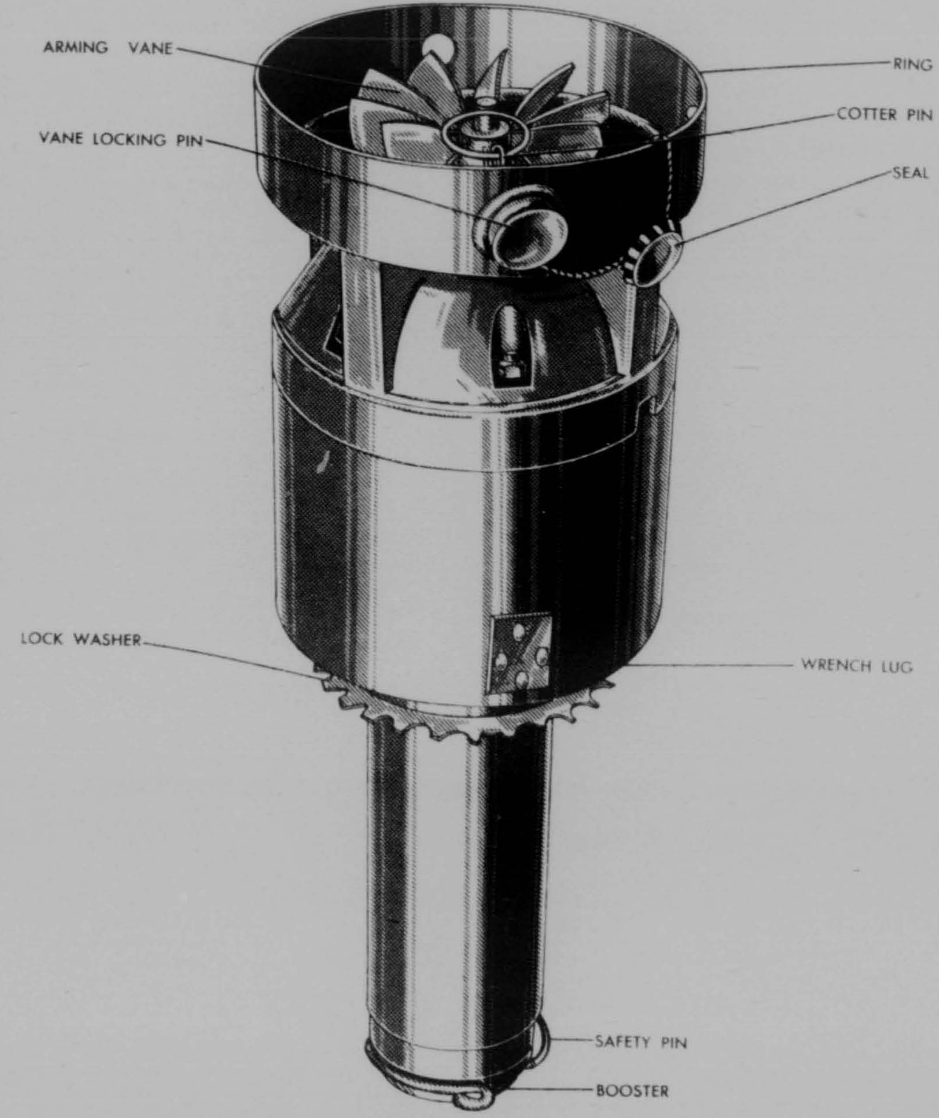

Figure 7—13. Ring-type VT Bomb Fuze.

THIS PAGE IS DECLASSIFIED IAW EO 13526

The length of the stop rod is measured accurately.

The safety pin is removed and the vane rotated carrier clockwise until the stop rod measures 0.4 inch less than the original measurement. (See below) This should require approximately 350 turns.

Safety pin is replaced and rewired.

A tag attached to seal wire indicating that the fuze is partially armed.

Fuze, bomb, AN-M100A1, or M100, when intended for bombs carried on external racks, will be partially armed as follows:

The seal wire and safety pin are removed. The cotter pin through the body of the fuze is left in place.

The cotter pin through the outer end of the arming stem is removed, then remove the arming head from the stem.

The arming stem is unscrewed (clockwise) from the plunger and removed from the fuze.

The threaded end of the arming stem is shortened 0.4 inch, taking care that all burrs are removed from threads after the cut is made.

The stem is screwed back into plunger until the holes in the stem and stem tube are in register. A pin is placed through the holes until the fuze is assembled.

Arming head is replaced on stem and cotter pin replaced.

The safety pin and seal wire are replaced.

A tag is attached to the seal wire indicating that the fuze is partially armed.

Fuzes partially armed by this method may also be used in bombs carried on internal racks and for purposes where partial arming is not required.

Marking. The fuze is stamped in the metal of the body with the type model and lot number. The sealing wire of the safety pin carries a tag which reads: "Remove pin after arming wire is in place but before attaching arming vane. Replace pin before removing arming wire if bomb is not dropped." In addition to the markings, this fuze is distinguished from the M112, and M123, as follows: the AN-M100A2 has a large arming head and the primer detonator has a single, wide, knurled band. The M112 has a small arming head and the primer detonator has two narrow knurled bands. The M123 is gearless with a direct arming drive.

The body of the fuze has a groove which contains a ball. The primer detonator (Figure 7-11) is marked to indicate the amount of delay.

Packing. Fuze, bomb, AN-M100A2 (tail) is packed, without vane assembly, one per container, 25 containers and 25 vane assemblies, on spindles in a wooden box.

SECTION III—NEW TYPE FUZES—VT BOMB NOSE FUZE, M166 & M168

New Types of Fuzes–VT Bomb Nose Fuze, M166 and M168

The radio-proximity fuze, generally referred to as the VT (variable-time) fuze during its development and combat use, is the perfect example of a "secret weapon." It was kept so for more than four years of development and production, and for more than two years of combat use throughout the world.

VT bomb fuzes produce air bursts on approach to targets such as water, earth, trees, or other objects, including aircraft, either airborne or grounded. No fuze setting is required, except for extended arming distances, when an arming delay is employed.

There are two general types of VT bomb fuzes, ring and bar.

The ring type is characterized by a heavy metallic ring around the arming vane. The M168 fuze is a ring-type VT fuze. Figure 7-13.

The bar type is characterized by metallic bars extending from both sides of the fuze

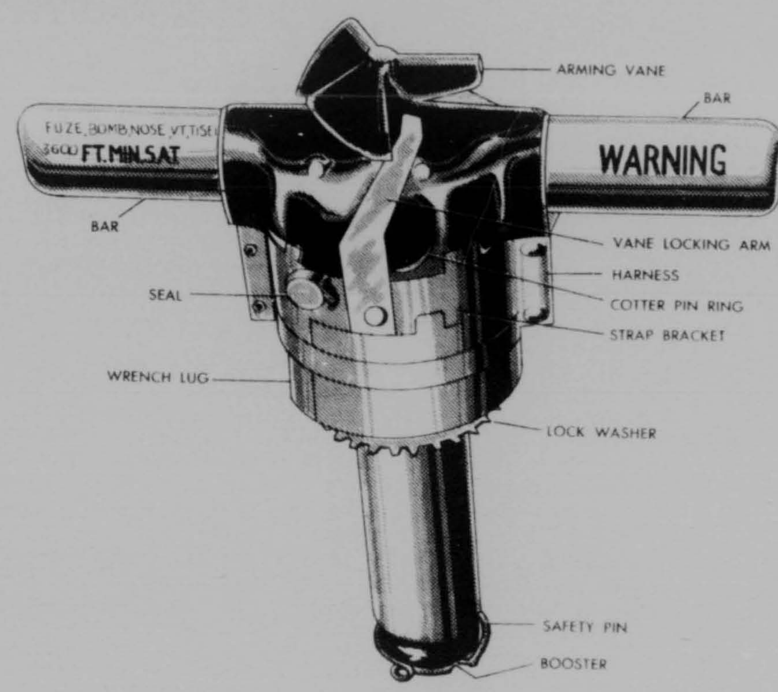

Figure 7—14. Bar-type VT Bomb Fuze.

nose. The M166 fuze is a bar-type fuze. Figure 7-14.

The use of VT bomb fuzes is advantageous in any plane-to-ground application where air bursting the bombs at heights from ten feet to one hundred feet will increase the effectiveness of the operation.

VT bomb fuzes were designed for use in any general-purpose, fragmentation, or chemical bomb weighing one hundred pounds or more which takes the nose fuze AN-M103 or AN-M103A1.

Characteristics of Fuzes

VT bomb fuzes will function automatically as they approach any target of suitable character, thereby causing an airburst to occur at an effective height. (Figure 7-15)

Height of Burst

Ring-type fuzes (M168) produce average heights of bursts from ten to forty feet, depending on the size of bomb, nature of target, altitude of release, and aircraft speed at release. Bar-type fuzes (M166) give heights of burst from forty to sixty feet. They are more nearly independent of bomb size, altitude of release and speed at release than ring-type fuzes. (Figure 7-16)

Effect of target. Figure 7-17. Functioning of all types of VT bomb fuzes is influenced by the character of the target. In the tables of burst-height, the target was assumed to be average dry earth. Over water, or wet earth, the burst height will be higher (approximately 100 per cent higher over water; over dry sand it will be approximately 50 per cent lower). The fuzes are influenced by the gen-

THIS PAGE IS DECLASSIFIED IAW EO 13526

Model of VT Fuze	Min SAT	Type	Bombs Size (lb)	Safety Pin	Adapted for Arming Delay	Maximum Altitude of Release
M166	3600	Bar	All sizes	Yes	Yes	Unlimited
M168	2000	Ring	100-220 250-260 2000	Yes	Yes	10,000

Figure 7—15. VT Bomb Nose Fuze Data.

eral characteristics of the target area. Dispersed trucks or mud puddles will not affect the height of burst but approach to large, high structures, such as buildings or dense foliage, will cause the fuze to function higher. Ring-type fuzes are more sensitive to passing a target, while bar-type fuzes are most affected by targets directly in their path.

Effect of altitude and speed at release. Ring-type fuzes are affected by the striking angle of the bomb, which depends upon true air speed and altitude at release. This dependence of burst height on release conditions can be used to advantage, since it provides a means of field control over burst height. Bar-type fuzes are relatively independent of striking angles.

Effect of bomb size. The height of burst of VT bomb fuzes is affected to a considerable extent by the size and shape of the bomb. Figure 7-16 lists several bomb and VT fuze combinations and heights of burst which may be expected from each.

Variation in height of burst. Manufacturing variations in component parts and in the fuze assembly lead to a spread in performance so that fuzes do not all burst at the same height under otherwise identical conditions. Figure 7-18 shows the spread in burst height characteristics of the M166 fuze.

Heights of burst are based upon approach of bomb to normal soil at release from 10,000 feet altitude at 200 mph true air speed, except for fuze M168 which was dropped from 8,000 feet altitude. "Low" means the burst occurs from 3 to 10 feet. Blank spaces indicate that no data is available.

Figure 7—16. Burst Height with Various Bomb VT Fuze Combinations (Feet).

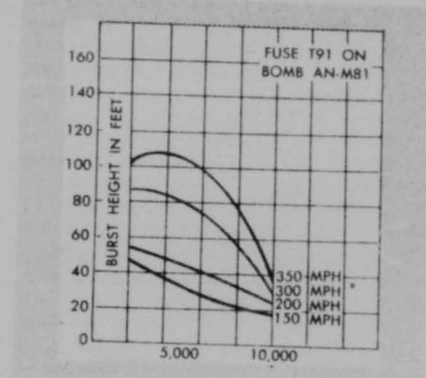

Figure 7—17. Release Altitude in Feet.

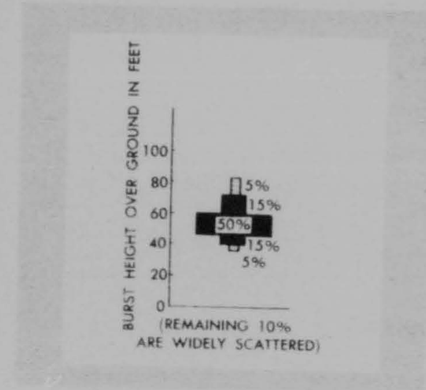

Figure 7—18. Height Dispersion Chart for M-166 Fuze.

Interchangeability

VT bomb fuzes are not operationally interchangeable with the AN-M103, because they are of value only when air bursts are desired. It may be seen in Figure 7-16 that burst height is affected by the physical dimensions of the bomb, particularly with ring-type fuzes.

Reliability

The development of VT bomb fuzes has now reached the point where more than 75 per cent of ring-type fuzes and 85 per cent of bar-type fuzes may be expected to function effectively.

Malfunctions

Malfunctions are of two types: an "early" function and a dud. An early function is a detonation of the VT fuzed bomb at some time after arming has been completed but prior to approach to a target; a dud is a VT bomb fuze which fails to fire.

Early functions. "Earlies" must be expected. The nature of the fuzes does not permit the total elimination of early functions at this time. However an excessive number of earlies (greater than 25 per cent) shows faulty operation and the handling and assembly procedures should be rechecked.

Duds. The effect of dud VT bomb fuzes may be partially compensated by use of a tail fuze of the M100 series in each bomb.

Train spacing. VT fuzes are designed to respond to a sudden change in their surroundings. An armed VT fuze may function due to the bursting of a nearby bomb. This restricts the minimum train spacing that can be used when bombs carry VT fuzes. Since the bursts of larger bombs are more violent, the minimum spacing required is greater for larger bombs. "Armed salvo" and "minimum train" releases will result in an increase in early functions. An intervalometer spacing of 50 feet or more for the 100-pound GP bomb AN-M30 or 260-pound fragmentation bomb AN-M81, or 100 feet or more for the 500-pound GP bomb AN-M64 is satisfactory. When bombs are filled with chemicals the required spacing is less (probably 50 per cent less) than it is for the HE loaded bombs.

Conditions Producing Malfunctions

Improper assembly.
Fin assembly not tight.
Fin assembly bent, damaged, or poorly fabricated.
Fuze damaged.
No lockwasher.
Fuze not tight.
Improper bomb selection.
Insufficient intervalometer spacing.
Rain.
Altitude of release. Too high. Too low.

Rain and Weather

Heavy rain (large drops), clouds, snow, and hail are likely to cause excessive early functions of VT bomb fuzes. Light rain, haze, sunlight, or darkness will not affect them.

Climatic Effects

Full advantage should be taken of the sealed fuze containers, as the unpacked fuzes are likely to deteriorate under warm and humid conditions. Fuzes should be unpacked only when required by the mission at hand.

Altitude and Air Speed at Release

No maximum altitude of release is specified for the M166 fuze. The M168 fuze must be released at altitudes of 10,000 feet or less. However, because of decreased vibration and bearing wear, releases at low altitudes may be expected to yield fewer early functions than releases at high altitudes.

Temperature

VT fuzes have been stored and used at temperatures between —40°F and +140°F without deterioration of fuze performance.

Ballistics

VT bomb fuzes are substantially ballistically interchangeable with bomb nose fuzes AN-M103 or AN-M103A1. Preliminary data available at this time indicate that no special bombing tables are required.

2. SAFETY AND ARMING

General Description of Fuzes

VT bomb fuzes are electric fuzes which develop their energy for proper functioning from a high-speed generator built in the fuze and powered by the arming vane. One of the safety features in these fuzes is an out-of-line electric detonator which is controlled by the arming vane. This detonator remains disconnected from the explosive train and from the detonator firing circuit until completion of arming. As soon as the bomb is dropped and the arming wire withdrawn from the fuze, the arming vane is released and wind stream rotates it at a high velocity. This rotary motion is reduced by a gear-reduction system which rotates the out-of-line detonator into the firing (armed) position and, at the same time, completes the electric circuit to the detonator, thus arming the fuze. The arming vane continues to rotate at a high velocity in order to operate the high-speed generator. The latter supplies current to an electric condenser for firing the electric detonator as soon as the VT fuze is influenced by approach to the target. Unless the condenser has been charged by high-speed operation of the generator, completely-armed VT bomb fuzes are safe to handle if necessary. After the condenser has been charged, sufficient time (sixty minutes) must elapse before an armed VT bomb fuze can be handled safely.

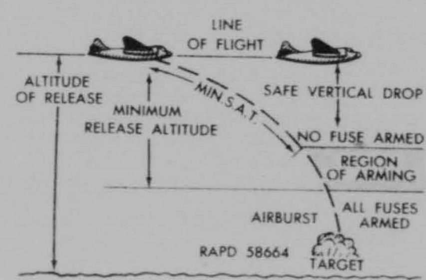

Figure 7—19. Arming—Air Travel—Vertical Drop.

Safe Air Travel

The fact that the arming vane must turn a given number of revolutions (1800 minimum) before the fuze becomes armed means that the bomb must travel a certain distance through the air after the vane is released before the fuze becomes operative. This distance is measured along the trajectory of the bomb and is called safe air travel (abbreviated SAT). Manufacturers' tolerances in parts and assemblies cause variations of a few hundred feet in SAT. Each lot of VT fuzes is tested on the 100-pound GP bomb AN-M30 to evaluate the minimum safe air travel (abbreviated MinSAT) prior to arming, for that lot of fuzes. The MinSAT, that air travel before which no fuze in the lot will arm, is marked on each fuze.

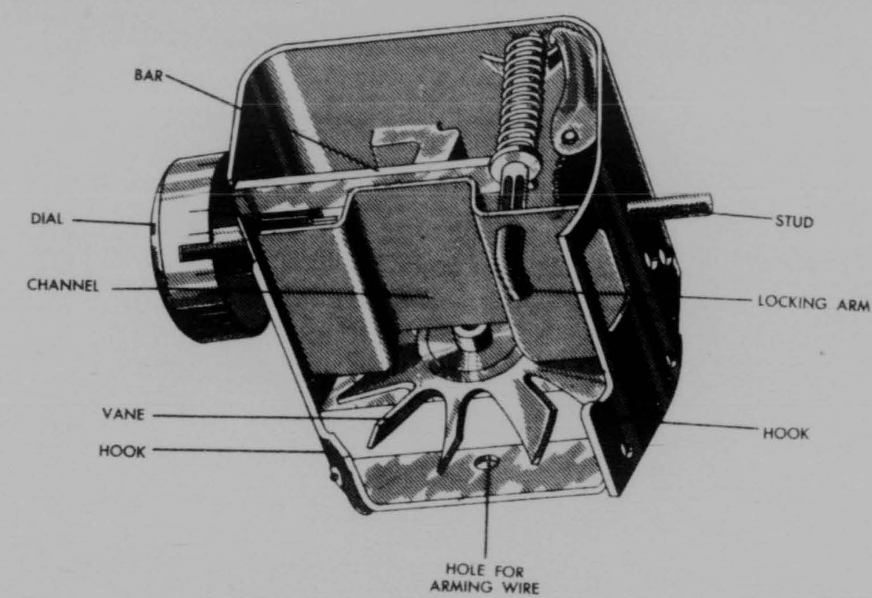

Figure 7—20. Arming Delay Air Travel, T2E1.

Arming Delay, Air Travel, T2E1

For operations which require safe air travel longer than that provided by the MinSAT of the fuze, an arming delay attachment is available for installation on the VT fuze. Arming delay T2E1 is shown in Figure 7-20. It can be used to increase the SAT of the fuze by any amount from 700 feet to about 20,000 feet. The device contains an air vane and a gear reduction system similar to that in the fuze. When the amount of air travel indicated by its dial setting has been traversed, the mechanism disengages itself, flies off the fuze, and releases the vane locking pin in the fuze. At this point, the fuze starts to operate and after a further air travel of the distance marked on it, the fuze is fully armed and operative. **The total safe air travel required to arm the fuze (SAT) is the sum of that of the fuze and that of the arming delay.**

Safe Vertical Drop

Determination of safe vertical drop is of importance from two standpoints:

Safety. It is vitally important that the safe vertical drop prior to arming is sufficient to provide adequate clearance for both the carrying aircraft and any friendly aircraft at lower altitudes. After a VT fuze is armed, it will fire on the first target it approaches, whether it is friendly aircraft, enemy aircraft, or ground targets.

Performance. It is important that the bombs be released at altitudes greater than the safe vertical drop. Otherwise, the VT fuzes will impact in the unarmed condition and they will not function.

Determination of Safe Vertical Drop and Minimum Release Altitude

When VT fuzes are used without arming delay, Figure 7-21 shows the safe vertical drop (SVD) and minimum release altitude (MRA) for each combination of MinSAT, bomb, and true air speed at release. The SVD indicates the vertical drop before which no fuze will arm and the MRA indicates the minimum altitude at which the fuzes should be re-

leased to insure that all are armed prior to impact. The tables are valid only for level flight releases.

When VT fuzes are used with arming delay, Figure 7-22 (A to F) shows for each combination of bomb and true air speed at release, the dial setting to be used on arming delay T2E1, for various release altitudes. The total safe vertical drop is shown for each case. The tables have been so constructed that for each altitude, the fuze is kept unarmed for as much of its fall as possible without the risk of impacting unarmed. The values are true only for level flight.

Safety Provisions

Seal. To insure that fuzes issued for use have the arming mechanism in the safe position, the vane is sealed at the factory to prevent rotation. If upon receipt of fuzes the seal is found to be broken, they should be handled with caution until destroyed or other disposition is made.

Safety Pin. Later models of VT fuzes (M166 and M168) are equipped with a safety pin inserted into the arming mechanism through an opening in the booster cup. An important feature of the safety pin is that fuzes whose seals have been removed can have the arming mechanism checked for safety in the field. This pin must be removed prior to fuzing the bomb. It can be inserted again only if the arming components are in the safe (unarmed) position. The presence of the pin, or the ability to insert the pin, gives visual indication that the fuze is entirely unarmed.

Damaged Fuzes

An unarmed VT fuze cannot fire. Dropping a packaged fuze will normally not injure it. Dropping an unpackaged fuze or a VT-fuzed bomb may injure the fuze but will not render the fuze unsafe. Damaged fuzes should be destroyed. Unarmed VT fuzes cannot fire and are entirely safe to handle and remove from bombs.

* True air speed. SAT figures are minimum and are in feet.

Figure 7—22F. Safe Vertical Drops (SVD) and Minimum Release Altitudes (MRA) for VT Bomb Fuzes.

An undamaged VT fuze will not fire unless the vane is turning rapidly (2000 rpm or more), even though it is armed. If the fuze is intact and the vane is not turning, it is safe to handle, except as noted below.

An armed VT fuze, damaged while the vane was turning at high speed, is dangerous. It should not be handled until after sixty minutes when it will be safe for necessary disposal. Before that time it may be sensitive to shock, jar, or approach.

An unarmed VT bomb fuze, even though severely damaged, should be safe. A fuze which becomes damaged when leaving the aircraft would most probably damage the arming vane and never arm. Approximately 2000 revolutions of the vane are required to arm a 2000 foot MinSAT fuze. A larger number of revolutions is required for fuzes with a greater value of MinSAT.

A VT fuze dropped from altitudes below the safe distances will function only in exceptional circumstances. Each lot of fuzes is checked against this in the acceptance test. The tail fuze, having a shorter arming distance, will govern the safety in such an instance.

3. FUNCTIONING

Released to Arm

When a VT-fuzed bomb is released armed, the arming wire is retained in the bomb shackle.

With No Arming Delay. As the bomb falls away, the arming wire is pulled from the vane locking arm (or pin) permitting the pin to be thrust away from the fuze by its spring, thereby releasing the arming vane. The wind stream turns the arming vane which arms the fuze after the bomb has traveled the distance specified as the MinSAT of the fuze. The armed fuze will fire upon approach to a target.

With Arming Delay. As the bomb falls away, the arming wire is pulled from the arming delay and vane locking arm (or pin). The wind stream spins the vane of the arming delay until the bomb has traveled the distance corresponding to the dial setting of the arming delay. At that point the arming delay disengages itself and flies off, releasing the vane locking arm (or pin), permitting the arming vane on the fuze to spin. From that point, the fuze begins to arm as explained above and having completed its arming, will fire upon approach to a target.

Released Safe

When a VT-fuzed bomb is released safe, the arming wire is disengaged from the bomb shackle and falls with the bomb. Since the arming wire does not release either the vane of the arming delay (if the arming delay is attached), or the vane locking arm (or pin), the fuze does not arm, and will impact in an unarmed condition. An unarmed VT fuze will not detonate upon impact, and may be dropped safe under any conditions permitted by the particular bomb in which it is assembled.

4. TESTING IN THE FIELD

Field Testing

No testing of VT bomb fuzes is possible in the field, except by dropping them in the bombs for which they are designed. Fuze lots may be checked for operational efficiency by dropping a representative sample of each lot. The samples should be taken from as many different boxes as possible.

Test Conditions

Tests should be conducted over water or level terrain if possible, in order to assess fuze performance under uniform conditions. Heights of burst over water will be about double those obtained over normal soil.

5. ASSEMBLING VT FUZES TO BOMBS

General

VT bomb fuzes are shipped to the field completely assembled, ready for installation in the bomb. Field assembly consists of installing the fuze in the bomb and, if tactics require it, adding an arming delay. It is recommended that wherever possible, the assembly operation be performed after the bombs are loaded into the bomb bay. In this case, care must be exercised to insure that the fuzes are assem-

bled sufficiently tight without causing damage to the bomb shackles. Where assembly in the bomb bay is impossible, or inconvenient, and regulations permit, the assembly may be performed with safety before the bombs are loaded.

Inspection

In inspecting the bomb assembly, no bombs having bent or damaged fins are used. Fin assemblies must be as tight as possible. The fuze well must be free of dirt, rust, or other foreign material. One also must inspect the fuze to insure that the vane and vane locking arm (or pin) is not damaged. If sealing wire is broken or missing, the fuze must not be used. It must be handled carefully until destroyed or safe disposition can be determined.

To Assemble Fuze

One removes the safety pin, if there is one, from the fuze booster.

The fuze is screwed into the nose fuze well of the bomb, by hand. The lockwasher must be in place.

The fuze is tightened as much as possible by applying fuze wrench T4 to the fuze lugs. If this wrench is not available another type may be used. Never hammer fuze or wrench handle, nor use bars of bar type fuzes as levers or handles. The bars should not be struck or twisted in any manner.

The sealing wire is cut and removed.

The vane locking pin or arm is moved to the hole in the ring (ring-type fuzes) or strap bracket (bar-type fuzes) nearest in line with the bomb suspension lugs. The arming vane should not be turned more than two or three turns during this operation.

To Assemble Arming Delay to Fuze

Preparation. The delay is placed on a flat surface, vane down, dial to right. The dial is freed by pressing the short projecting stud on left face down and outward. Holding the bar across the top of the arming delay down, the dial is turned until bar is in line with slot in dial. The bar is released carefully to avoid injury from spring action.

Assembly. The short end of the arming wire is threaded through the front suspension lug through the small hole in the strap on the vane end of the arming delay and through the hole in the vane locking arm (or pin) where the seal wire was.

The arming delay is placed with its vane-end toward the bomb tail, so that the channel is over the vane locking arm (or pin) and the hooks of the arming delay engage the bottom of the fuze ring or strap bracket.

The bar is turned back in place through the slot in the dial.

The stud is pressed as before, and the dial turned to the desired setting.

The arming wire is adjusted to protrude two or three inches in front of the fuze nose. A safety (fahnestock) clip is never used. The force of the spring, after the cotter pin has been removed, is sufficient to hold the arming wire firmly in place.

The cotter pin is removed.

To Assemble Arming Wire (When Arming Delay Is Not Used)

The short end of the arming wire is threaded through the front suspension lug and through the hole in the vane locking pin (or arm) where the seal wire was.

The arming wire is adjusted to protrude two or three inches in front of the fuze nose. A safety (fahnestock) clip is never used. The force of the spring, after the cotter pin has been removed, is sufficient to hold the arming wire firmly in place.

The cotter pin is removed.

Tail Fuze

A tail fuze of the M100 series (instantaneous) should be used as insurance for bomb detonation on ground impact in case the VT fuze is a dud. Testing assembling, and attachment of arming wire should follow normal procedure for the fuze employed.

Caution

Care should be exercised with bar type fuzes to make certain that those on the bottom station have bars oriented horizontally. Otherwise, in some instances, the fuzes will be damaged when the bomb bay doors are closed.

6. TO REMOVE VT FUZES FROM BOMBS

General

If the plane returns with its bombs, and when use of the fuzed bombs within forty-eight hours is unlikely, the fuzes should be removed from the bombs, returned to their containers, and sealed as tightly as possible.

To Remove Fuze

Cotter pin is replaced in the vane locking pin (or arm).

If arming delay is present it is removed by pressing the stud toward the fuze. Holding bar across open end, the dial is turned until the dial slot is in line with the bar. Arming delay is released by sliding it back along the arming wire.

Arming wire is pulled from vane locking arm (or pin).

Sealing wire is inserted through hole vacated by arming wire, and ends are twisted around ring or harness strap.

The fuze is loosened with fuze wrench T4 until it may be removed by hand. If the fuze has not been assembled tightly, removal of the fuze may be facilitated by first flattening lockwasher by further tightening of the fuze.

Fuze is removed from fuze well. Lockwasher must not be lost and is kept with fuze.

Safety pin is replaced through booster cup if fuze was equipped with safety pin.

Fuze is replaced in container. Container is resealed as tightly as possible.

Disassembly of Fuzes

VT bomb fuzes must not be disassembled under any condition.

SECTION IV—ROCKETS & RELATED FUZES

1. HISTORICAL HIGHLIGHTS IN ROCKET DEVELOPMENT

Chinese and Arabs in the thirteenth and fourteenth centuries attached gun powder to fire arrows which had been used for a long time. The fire arrows had been used as incendiaries by attaching masses of pitch, tar, and oil-soaked rags. They were ignited just prior to firing from bows. With the addition of the gun powder in paper cases, the arrows became self-propelled when ignited.

The first notable military use of rockets was in India at the end of the eighteenth century when the princes of Mysore defended their towns against siege by the British with as many as five thousand flames-throwing rockets. Although the British captured the town despite this unusual defense, the latter saw the need for experimentation in the military use of rockets. Most notable of the early British experimenters was William Congreve who succeeded in perfecting several rockets suitable for military operations.

In 1805, the British dispatched special rocket boats against the French seacoast town of Boulogne. Rough weather prevented their use on this occasion but the following year considerable damage was done to the town and military stores by many fires caused by flames of two hundred rockets fired from eighteen boats. The rockets were fired in half an hour from a distance about half a mile.

In the latter part of the nineteenth century, with the advent of rifling breech loading, recoil mechanisms, smokeless powder and advancement in metallurgy, rockets were discontinued in warfare. At the turn of the present century, Britain declared rockets obsolete for military use, when after a fire in Woolwich Arsenal, considerable stores of rockets were destroyed without a single loss of life. It was considered that so great a loss of military

stores could not produce such inconceivable lack of injury and loss of life, if rockets had any military value.

During the years 1939 to 1941, the British produced some good antiaircraft rockets. The British rockets stimulated interest in this country and our rockets were patterned after those of the English. Meanwhile, the Germans had collected extensive material on rocket research which had been taken over by the German Army in 1935. By the start of the war, they had developed many types of offensive and defensive rockets. The use of aircraft rockets by German aircraft was finally responsible for the discontinuance of daylight bombing without fighter escort. Ironically, much of the early information which started the Germans on their intense rocket research, came from the experiments and achievements of an American inventor and scientist, Dr. Robert Hutchings Goddard, whose great work went unrecognized here in the United States in the peaceful years that followed WW I.

2. USES OF ROCKETS IN MODERN WARFARE

The earliest practical use of rockets was in the field of communications. It was found that rockets were especially valuable at night as a distress signal at sea, because the rockets were visible at considerable distance. By taking a bearing on the source of the rocket trajectory, rescue boats were able to save a great number of lives of those drifting helplessly at sea.

Since rockets could be illuminated with several different colors, it was possible to use rockets as signals to convey messages. Consequently, colored rockets found much use both in war and peace as signals and a means of communication, especially on the sea at night, or on the battlefield. By the use of various color combinations, many simple messages could be conveyed quickly over several miles distance.

A later use of rockets was in the pyrotechnic field to assist planes in locating an airport that was closed in by the weather or poorly lighted at night. Flares attached to the rockets, or star clusters, which burst at the highest point in the rocket's vertical flight, were visible to planes at considerable distance from the air field. By following the light of the flares or rocket bursts, which were sent up at regular intervals, lost planes could soon locate the airport. At present, this use of rockets is practically obsolete due to advances made in navigation and instrument landings.

Still another use of rockets was at sea to convey a line or rope from land to a foundering boat or from one boat to another. A light line would be attached to the rocket which would be made to pass low over the foundering boat. When the rocket dropped in the sea, the light line dropped across the deck of the vessel and was used to pull in a heavy rope for towing purposes, or to pull in a cable for transferring passengers by means of a breeches buoy.

The military use of present day rockets is well known. Aircraft rockets have the same effective action as projectiles from 155-mm guns and are very useful against many military targets such as locomotives, tanks, vehicles, planes, buildings, boats, gun emplacements, and harbor installations, as well as against enemy aircraft both in the air and on the ground.

The latest use of aircraft rockets has been in research of the upper air. Rockets have been sent up to a height of 114 miles and it is expected they will go much higher. Within the head of these rockets, is placed a container of many delicate scientific instruments. At the rocket's extreme height the instrument container is jettisoned and brought to earth gently by means of two parachutes, one of which is a small one that opens at the highest altitude; the other a larger one that opens at a lower altitude usually about twenty-eight miles. The point at which the instruments drop to earth is located by means of radar and a helicopter. Data from the weather instruments is being used in long range weather forecasting. Other data aids in the design of future stratosphere supersonic or even hypersonic aircraft.

3. ADVANTAGES OF AIRCRAFT ROCKETS

The use of aircraft rockets has expanded at an incredible rate. In the year 1945, the year of greatest production, the Navy alone was spending as much as $100,000,000 a month for rocket ammunition. The use of rocket ammunition became automatic for amphibious landings after just a few trials. The reason for this sudden expansion was due to the fundamental advantages of the rocket over artillery.

In the airplane, the aircraft rocket had far greater range than the heaviest gun that the aircraft could carry without major modifications. The trajectory was flatter for aircraft rockets than ground rockets due to the speed of the plane added to the initial speed of the rocket. Consequently, the accuracy was exceptionally good. The principle of reaction by which rockets are impelled, brings about a third definite advantage, namely lack of recoil of the mount or launcher. The consequence to this is no shock of firing to the airplane and a very light launching apparatus may be used. As a direct result, the load on the airplane is much less than if a heavy gun mount had to be carried. Although, at present only a few sizes of rockets are used, a wide range of rocket sizes is feasible on aircraft. The gentle takeoff of a rocket allows high-powered, but more sensitive, explosives to be used. Other advantages are the high speed and range of larger rockets which makes interception and countermeasures a difficult problem. Also, small rockets are adaptable to the use of space charges which make possible extremely great penetration power despite the slower speed of the rocket. Still another advantage is that rockets have made possible research into the ionosphere or upper air at higher altitude than ever before attained by man. Stepped rockets show promise of even going much higher and are theoretically capable of velocities great enough to leave the gravitational field of the earth into interplanetary space at hypersonic speeds of 5000 or more miles per hour.

4. LIMITATIONS OF AIRCRAFT ROCKETS

Temperature Limitations

Rockets such as the 4.5" M8A3 rocket have operating limits set at 10°F and 105°F. Other rockets operate from 0°F to 120°F and from 40°F to 120°F. However, by special procedure and added safety measures, it is possible to fire between limits, 40°F and 140°F. Below and above these temperatures present military propellants can not be used with dependability or safety. Certain test rockets are being designed for greater temperature range.

Accuracy Limitations

Rockets do not have the accuracy at longer ranges of artillery where destruction of a specific target is required. However, they are ideal against area targets because many launchers can be assembled rapidly at one point and fired at a high rate of fire with great destructive result. When accuracy can be sacrificed for time, that is when ability to fire any ammunition is more important than the accuracy, or when fired at relatively short ranges, rockets are the ideal military weapon for high destructive power.

Efficiency Limitations

Rocket missiles are not as efficient as artillery projectiles because they are heavier than a shell of equal explosive weight, owing to carrying the propellent charge and burned-out motor tube through the air as dead weight, and fragmenting it at the target. However, when overall weight is considered, the rocket compares favorably. For example, the 4.5 rocket and launcher weighs 55 pounds total compared to 4000 pounds for the 105-mm howitzer of about equal fire power. On the other hand, rockets of the same caliber as artillery, in general, have the lesser range.

Disadvantage of Blast

The blast from a rocket jet endangers personnel and equipment near the launcher. It is important that nothing be in the way of the tremendous rear blast of the intensely-hot, propellent gases for at least the danger distances published in the instructions for each rocket. Aircraft in formation must observe these rules when firing to prevent possible damage to a following friendly aircraft.

Hazards of Manufacture, Transportation, and Storage

In general, rocket propellants are somewhat more dangerous than other propellants

to manufacture. Solid propellents often have to be made by the solventless process or dry method which is more dangerous than the solvent method used for making the ordinary smokeless-powder propellents. Transportation and storage are also more dangerous due to the fire hazard and sensitive nature of rocket fuels which cannot withstand the shock of rough handling. Since more sensitive explosives can be used in the war head of rockets, storage of these is more dangerous. Some of the liquid fuels, such as liquid hydrogen and various hydrocarbons used, present special storage problems. Oxidizing agents such as liquid oxygen and hydrogen peroxide are dangerous to handle and store. Fortunately, most of these agents are not used in aircraft rockets.

5. BASIC PRINCIPLES OF ROCKET FLIGHT

Newton's Third Law of Motion

The principle upon which rocket flight depends was stated by Sir Isaac Newton in 1679, namely: To every action there is always an equal and opposite reaction. An example of Newton's third law of motion is the kick of a rifle. The momentum or mass X velocity, MV of the bullet is equal and opposite to the momentum MV of the rifle. This is understandable when one realizes that the velocity of the bullet is high but its mass or weight is low, whereas the weight of the rifle is high in comparison to that of the bullet. The momentum not taken up in the acceleration of the rifle is resisted by the thrust against the shoulder of the person firing. Another example, more typical of the reaction in a rocket, is that of a rapidly deflating, free to move, rubber balloon.

6. IDEAL PROPELLANTS AND GENERAL REQUIREMENTS OF ROCKET PROPELLANTS

There are two delicately-balanced factors which are closely related to the movement of a rocket; first, the burning of the powder tending to increase pressure within the rocket, and second, the escape of gases tending to reduce the pressure within the rocket. These factors are influenced by the composition of the powder, shape of grains and rate of burning as well as features of the rocket design. In order to gain the most desirable results, **an ideal propellant for rockets would have the following characteristics:**

Ignite and burn uniformly at low pressure.

Have a well-defined reproducible and approximately constant burning surface.

Nonhygroscopic.

Procurable in grains having burning times variable through wide limits.

Possess adequate mechanical properties.
Smokeless.
Flashless.
Stable.
Not affected by temperature variations.

Another general requirement of rocket powder is that the grains be much larger than those of artillery powders to make for ease of mounting in the motor tubes and on trap assemblies. The powder should also be somewhat slower burning than artillery powders. The large grains require a solventless or dry manufacturing process rather than the wet or solvent process because of the long drying times and warpage which occurred in the latter process. No one powder could satisfy all these characteristics and general requirements, but double base powders have proved quite satisfactory.

7. FUNCTION OF PROPELLANT COMPONENTS

The plasticizer is used as a bond. The opacifier absorbs heat of radiation, preventing rapid decomposition within the powder by the heat. This decomposition would eventually cause an internal powder pressure which would cause breakage of the grain. The stabilizer absorbs gaseous products of slow decomposition and generally reduces hygroscopicity or tendency to absorb moisture. The flash depressor works its result by cooling of powder gases. The grain is made in cruciform, or cross shaped section. A portion of the surface of the grain is covered with fire resistant plastic strips which are inert and act as inhibitors preventing the burning surface from becoming too great which would increase the burning rate above the desired limits. In some rockets, the grains are cylindrical, perforated at the center to prevent degressive burning and so that they can be supported on wires threaded through the central hole. The support for the grains is known as a grid or trap assembly.

8. EFFECTS AND ADJUSTMENTS FOR TEMPERATURE

High ambient temperatures increase the burning rate. In certain rockets, the powder charge is reduced when the surrounding temperature is too high. This adjustment reduces the range, but does not appreciably affect the velocity of the rocket during burning time. In other rockets, an additional central nozzle is plugged with a thin metal disc which blows out at high temperatures and pressure, causing a reduction in internal pressure, allowing the rocket to function without harm at high ambient temperatures. Low ambient temperatures increase the chances of failure to ignite and also cause "chuffing" which is the extinguishment of burning for a brief period and then reignition, causing the rocket to go on a haphazard trajectory; low temperatures also cause condensation of moisture within the rocket which tends to cause an increase in hygroscopicity and temporary slowing of the burning rate. The only adjustment for low temperature is to use a different composition powder which is suitable for these requirements. The temperature range of newest propellants is from 40°F to 140°F.

9. STABILITY OF ROCKET FLIGHT AND ACCURACY

Rotation

Rocket launchers, unlike guns of artillery, have no rifling and consequently do not impart rotation to the rocket. Fins may be attached to the rear of the motor body to obtain stability; such rockets are called fin-stabilized rockets. In other rockets, a ring of nozzles may be used instead of a single central nozzle, each separate nozzle being canted sidewise so that the passage of the propellent gases through them imparts rotation to the rocket; such rockets are called spin-stabilized rockets. Fin-stabilized rockets might rotate slowly because of some irregularities of the fin construction but no induced rotation is intended. Spin-stabilized rockets are more accurate than fin-stabilized rockets because malalignment of the jet is unimportant since the rapid spin tends to average out its effects and the absence of fins eliminates drag. A fin-stabilized rocket of 4.5 inches, such as the M8 type, has $1\frac{1}{2}$ times the dispersion of the spinner type rocket M16 of 4.5 inch size. Rockets fired from aircraft with increased linear velocity require also an increased angular velocity or stability will be reduced.

Effect of Wind

The accuracy of rockets is obviously improved by firing them from aircraft in the same direction as the plane's flight, because the rocket has the added velocity of the plane as a component. Furthermore, there is a tendency of the rocket to turn into the wind. Consequently they should be fired either against the wind or with the wind, but not cross wind or from the plane during a turn, which has the same effect on the rocket's accuracy. Slight winds up to thirty miles per hour may be compensated for by windage adjustments on the sight without decrease in accuracy. Rockets fired from aircraft have from one-fifth to one-third the dispersion of rockets fired on the ground, depending on the speed of the aircraft from which they are fired. It must be noted, also, that upper winds do not have the same velocity and direction as surface winds. All wind corrections for rockets and bombs are based on the wind effect at a definite-speed dive angle and slant range. It has been stated, contrary to general belief, that cross-wind dives give as great an accuracy as up-wind or down-wind dives when only one type of projectile is used. Using combinations of weapons the up-wind and down-wind dives are better; the wind effect is proportional to the sine of the angle of dive times the velocity of the wind at the release altitude. This means that for each angle of dive the 90 degree cross-wind effect remains relatively fixed. Head winds, tail winds, or target movements are proportional to the cross-wind effect times the sine of the angle of dive.

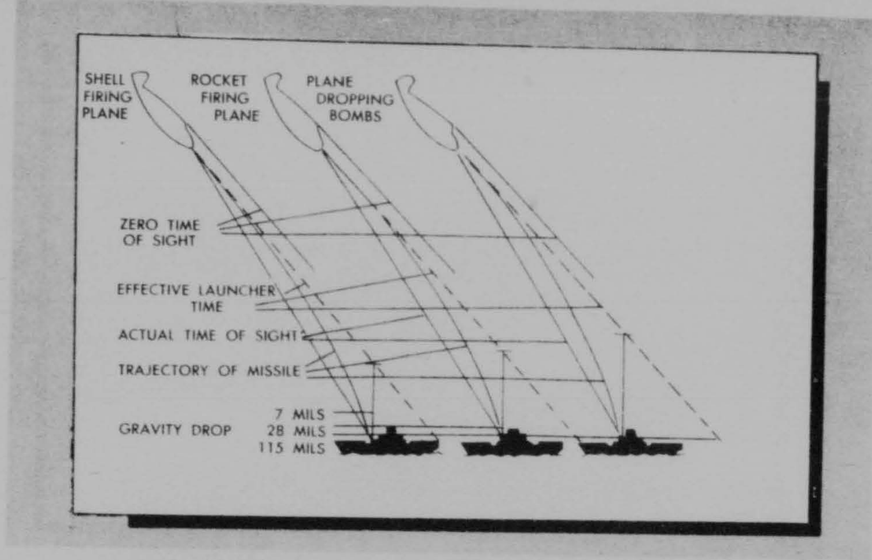

Figure 7—23. Typical Rocket Trajectory Vs. Trajectories of Shell and Bomb.

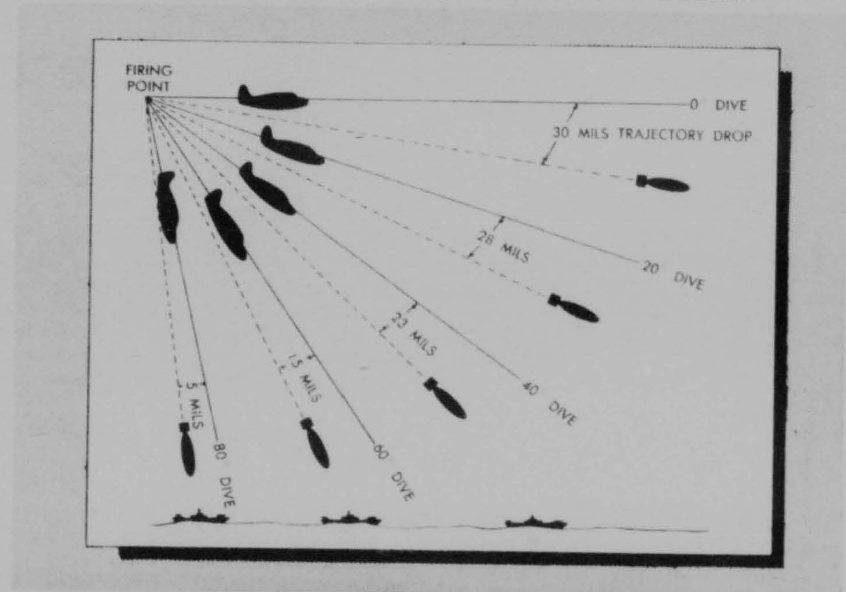

Figure 7—24. Effect of Dive on Trajectory Drop.

THIS PAGE IS DECLASSIFIED IAW EO 13526

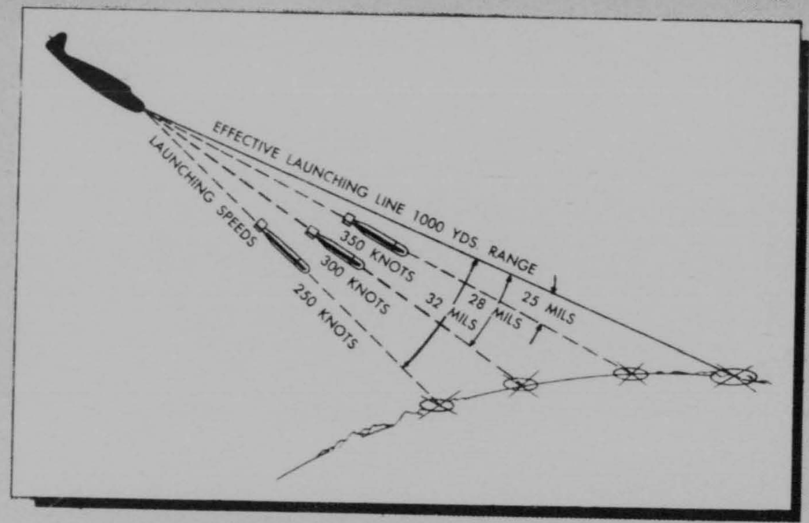

Figure 7–25. Effect of Launching Speed on Rocket Trajectory.

10. ROCKET TRAJECTORIES

Rocket Trajectories Versus Shell and Bomb Trajectories

Rocket trajectories lie between the trajectories of demolition bombs and the trajectory of shells. For example, for the same line of sight angle, the gravity drop of a shell is 7 mils, that of a rocket 28 mils and that of a demolition bomb 115 mils, a mil being the angle subtended by a chord 1 yard long at a distance of 1000 yards, or 1/6400 of the circumference of a circle. It will be noticed that the rocket trajectory is characterized by considerable curvature in contrast to the relatively straight trajectory of the shell. Since the rocket is slower than the shell, the longer time of flight for a given range tends to align it along the trajectory so that there is also a component of the jet force downward contributing to the drop from the launching line. Due to the consequent large curvature of the rocket trajectory, the sighting allowance required in aiming and its variation with dive angle are much greater for rockets than for shells. These differences, however, are less for shells than those for bombs. (Figure 7-23)

Effect of Dive Angle on Trajectory Drop of Rockets (For 0°, 20°, 40°, 60° and 80° Dives)

The trajectory drop decreases as the dive angle is increased, the drop varying roughly as the cosine of the dive angle. The sight setting is thus decreased as the dive angle is increased. However, the dive angle also affects the sight setting through its influence on the angle of attack of the aircraft. (Figure 7-24)

Effect of Launching Speed on Rocket Trajectory

The true (not indicated) air speed affects the gravity drop of a rocket. The greater the true air speed of the airplane at launching, the less will be gravity drop. This is a small effect compared to the effect of indicated air speed on altitude of the aircraft. (Figure 7-25)

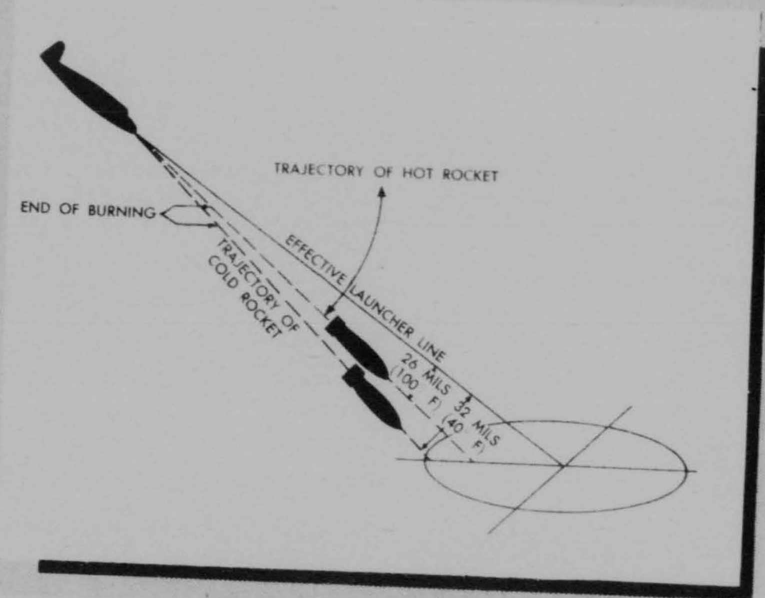

Figure 7–26. Effect of Temperature on Rocket Trajectory.

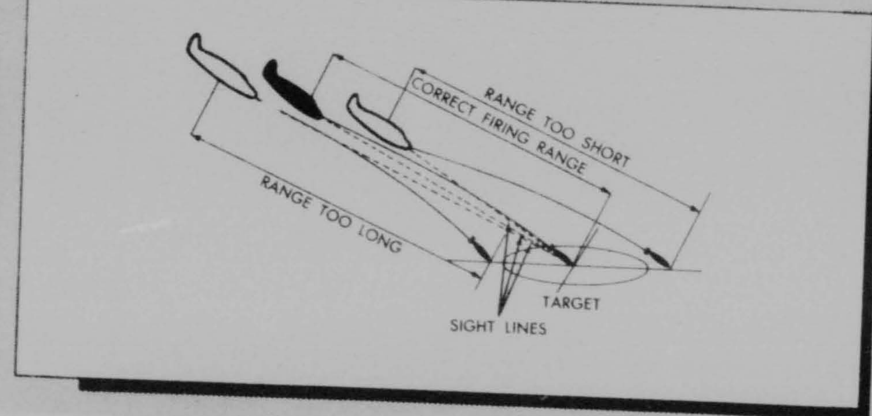

Figure 7–27. Effect of Range Misestimation.

THIS PAGE IS DECLASSIFIED IAW EO 13526

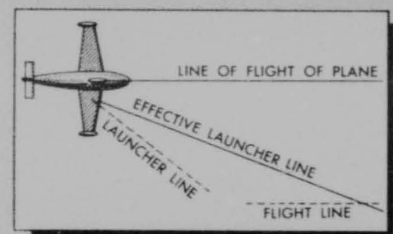

Figure 7—28. Effect of Flight Line on Rocket.

Effect of Temperature on Rocket Trajectory

The burning time and consequent burning distance of a rocket depend very greatly upon the temperature of the rocket propellant at ignition. Hence, since the trajectory drop is greater for increased burning time, it is obvious that the mil drop is greater for cold than for hot rounds. With some rockets, this may be a very important correction. For the 5.0" HVAR, the allowance is about 1 mil for each 10°F for firing at 1000 yard range in a dive at 300 knots. The variation is greater at the slower airplane speeds. (Figure 7-26)

Effect of Range Misestimation on Rocket Trajectories

It is important to judge range correctly because of the large curvature of the rocket trajectory. The errors due to range misestimation are apt to be the largest of those occurring in forward firing unless ranging equipment is available. For the 5.0" HVAR at 70° F fired in a 20° dive at 300 knots, the mil error for each 100 yards of range error is 1.6 mils. This figure increases for shallower dives and slower airplane speeds. (Figure 7-27)

Effect of Flight Line on Rocket, or Tendency of Rocket to Turn Into Flight Line Due to Malalignment of Launcher

Rockets tend to turn into flight line when launcher is canted from axis of airplane. The large fins which are employed in fin-stabilized rockets also make the rocket sensitive to the direction of the airstream past the aircraft.

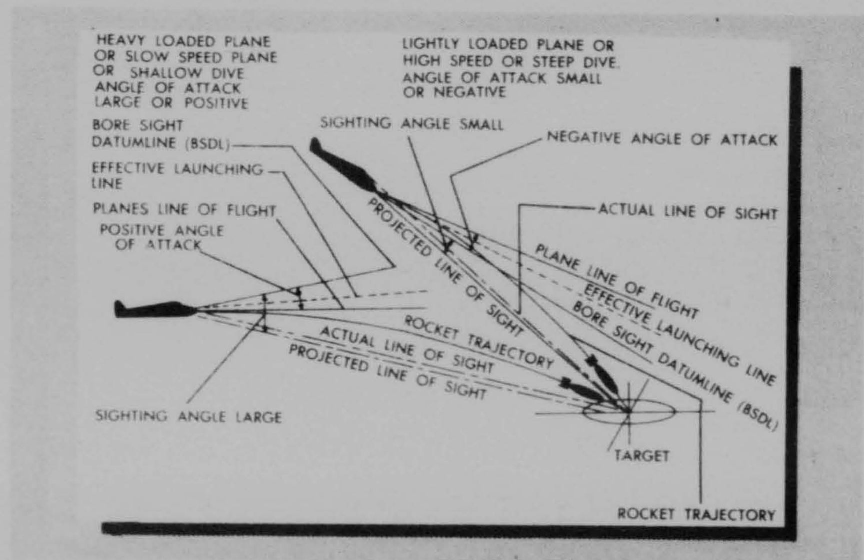

Figure 7—29. Effect of Angle of Attack on Aiming.

A rough rule is that fin-stabilized aircraft rockets launched from zero or post launchers follow the line of flight of the aircraft rather than the line of launch established by the post launchers. Launchers malaligned as much as 10 degrees causes the rocket to turn completely into the line of flight. Malalignment over 10 degrees causes approximately 90 per per cent complete turning into the line of flight. (Figure 7-28)

Effect of Plane Attitude or Angle of Attack on Aiming

Since the sighting angle is measured from a fixed line in the airplane (generally the boresight datum line BSDL), any change in orientation of this line will necessitate a change in the sighting allowance; hence an increase in the angle of attack BSDL (which means that the BSDL rides higher with respect to the flight line and the sight line to the target) will result in a large sighting angle. Conditions which tend to increase the angle of attack (and thus the sighting angle) are shallow dive, low indicated air speed, or heavy airplane loading. It is the indicated air speed, not the true air speed, which affects the angle of attack. The indicated air speed is dependent not only on true air speed, but on the pressure and temperature of the surrounding air or ambient temperature, which in turn varies with the altitude and climatic conditions. (Figure 7-29)

11. SIGHTING AND AIMING

As long as the aircraft follows a steady curve of approach in the attack, its line of flight will remain essentially unaltered even though bumpy air may cause rapid fluctuations in the relative position of pip and target. Therefore, a slight wandering of the aim around the target will not have an adverse effect on the accuracy provided the wandering is not consistently high or low or to one side. However, when the average aim point during approach is off the target, as illustrated in Figure 7-30, even though the pilot moves the pip on to the target at the instant of firing, the rocket will not strike the target, but will strike the average aim point instead.

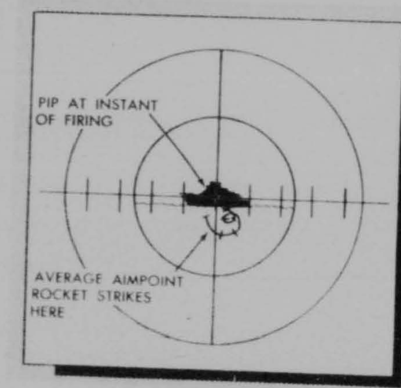

Figure 7—30. Effect of Wandering Sight Line.

The recommended approach, once the pilot is in the attack dive, is to get the pip on the target at least one second before reaching the firing range and keep it there until the instant of firing. Whether positive or negative attitude is induced on the aircraft in this curve of approach depends on whether or not the airplane is still accelerating, and on the range, air speed, sight setting, wind, and characteristics of the airplane. The motion of the target, if moving at rapid speed, must be taken into consideration, especially against aircraft targets, in which case proper lead must be taken depending on the speed of the rocket being fired. It is important, therefore, that complete information on sighting instructions be obtained both for the type or model of airplane as well as the type of rocket being fired. These may be found in Technical Orders pertaining to that aircraft and in rocket firing tables.

12. CLASSIFICATION OF AIRCRAFT ROCKETS

Aircraft rockets being similar to other ammunition, as far as the mission to be performed at the target is concerned, are classified similarly. The general classifications are as follows:

According to Service Use:

Service rockets are used for performing a mission at the target because they are fired against the enemy.

4.5 INCH ROCKETS

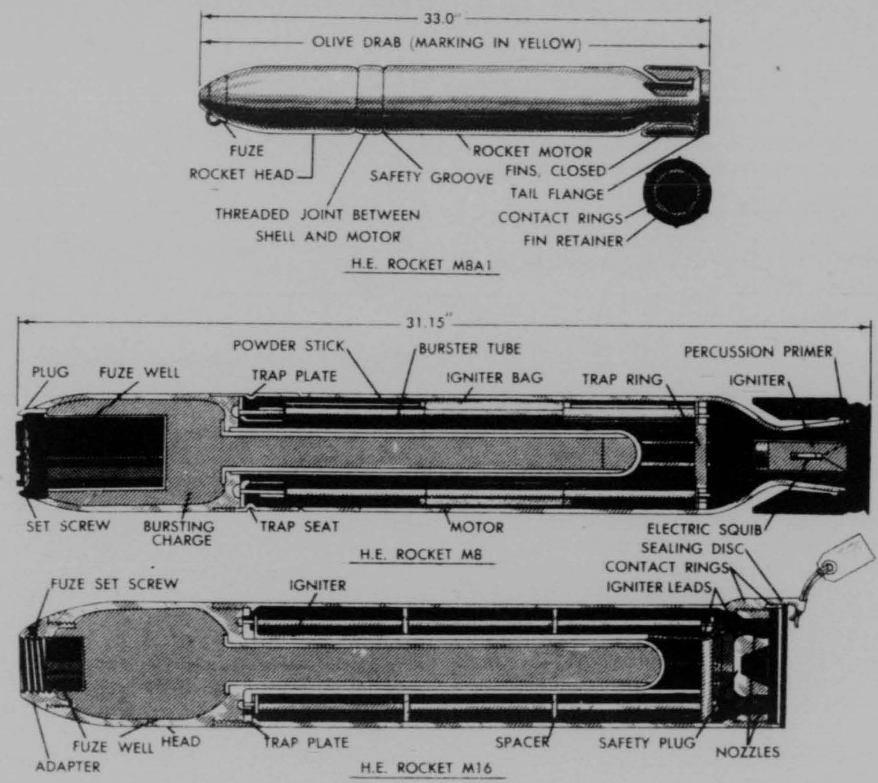

Figure 7—31. Sections of Unfuzed Rockets.

Practice rockets, and subcaliber rockets are used for marksmanship training and operation of launchers.

Drill rockets are used for training.

According to Tactical Use:

High-explosive rockets are those with high-explosive heads for demolition and fragmentation.

Armor-piercing rockets are those with heavy armor-piercing heads and smaller explosive percentage.

Semi-armor-piercing rockets similar to the SAP Bomb, are a compromise between HE and AP rockets.

Chemical rockets have heads loaded with chemicals.

According to Method of Stabilization:

Fin-stabilized rockets are equipped with either fixed fins, or folding fins.

Spin-stabilized rockets are equipped with several nozzles canted sideways from the axis of the rocket, so as to create a torque which makes it spin.

Target Rockets:

For training of antiaircraft artillery batteries or for rocket-interceptor training in defense against rockets.

13. ROCKET COMPONENTS

Head (Payload)

The function of the head is to destroy the target by blast, fragmentation, or otherwise. Rocket heads are classified as high explosive (HE), high-explosive antitank (heat), semi-armor-piercing (SAP), chemical, flare, photo-flash, instrument-loaded, parachute, and practice. The type of filler can be identified by markings on the head. The head may use either or both nose and base fuzes which are threaded into adapters. Booster cups are also contained in the head to insure detonation of the explosive charge. (Figure 7-31)

Motor

The purpose of the motor is to give the rocket its propulsion or motive power. Its principal parts are as follows:

Motor Tube. This is a seamless steel tube threaded at one end to receive the head. It encloses the combustion chamber in which the propellant is burned. It houses the solid or liquid fuel. If liquid fuel is used, the combustion chamber is sometimes surrounded with double concentric tanks which serve the double purpose of cooling the combustion chamber and preheating the fuel. The oxidizing agent, such as liquid oxygen, and the fuel, such as kerosene, each occupy one of the concentric tanks. This type of rocket is known as regenerative. At present there are no liquid-fuel aircraft rockets. The suspension bands provide either button-type lugs, or tunnel-type lugs for suspending the rocket attached to the motor tube. Usual distance between centers for aircraft rockets of lugs is either approximately 17½ inches or 35¼ inches. The walls of the motor tube are relatively thin, usually less than 0.25" because of comparatively low pressure. Near the head there is a safety ring groove which allows the tube to break at this point in event of excessive pressure in the combustion chamber.

Trap (Grid). The trap supports the powder grain before and while burning, and at the same time, allows enough clearance for the gases to escape. Traps vary in form and dimension. Perforated grains usually are strung on wire traps. Single grains are molded onto the trap frame.

Propellent Grain. Double-base nitroglycerine, nitrocellulose powder is either perforated to prevent degressive burning or is shaped to provide the desired burning characteristics. It may be provided with surface inert strips known as inhibitors to limit the amount of surface exposed to burning.

Pads, Washers, Spacers. Between the end of the propellent grain and head is usually a felt pad to cushion shock to the propellant. There is also an inlet filter washer and a hollow spacer to prevent the melted motor components and fragments of debris from clogging the pressure vent to the base fuze, which in many cases is pressure armed. A blowout disc is provided on this pressure vent. A metal shipping cap protects the threads on the motor.

Nozzle. The nozzle is a venturi-shaped orifice consisting of a convergent section, a throat of minimum diameter, and a divergent section which directs the flow of gases in the desired direction and provides for expansion of the gases in the exit cone to as close to atmospheric pressure as practical without having the exit cone too long. The venturi shape allows nonturbulent expansion of gases and provides an additional 33 per cent thrust over a simple convergent opening. In spin-stabilized rockets the nozzles are arranged symmetrically about a circumference but each with its axis canted from the rocket axis so as to provide a torque causing rapid rotation. Prior to firing, the nozzles are plugged with a sealing compound to protect the propellant from moisture. These seals are blown out when the rocket is fired.

Igniter. The igniter is a device for precisely igniting the propellent, thus initiating functioning of the rocket. An igniter such as the bayonet type consists of four parts: a squib, electrical connections, a charge of black powder, and the body or case, which is made of a special celluloid resistant to nitroglycerine which softens ordinary celluloid. Celluloid or other plastics are required to seal the hygroscopic black powder from moisture. The plastic seal for the black powder is better than

THIS PAGE IS DECLASSIFIED IAW EO 13526

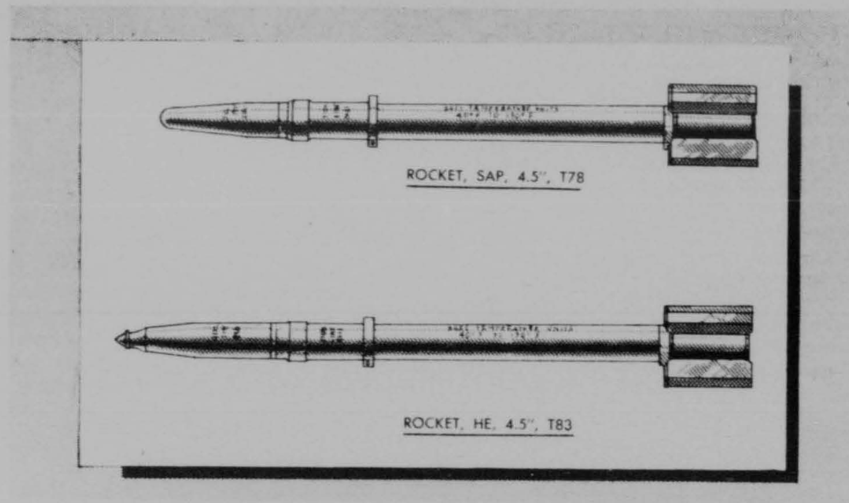

Figure 7—32. 4.5 Inch Fixed Fin Rockets.

having it loose in bags because shorter ignition times are obtained, thereby benefiting the accuracy by firing at the instant of aiming. The normal firing delay is between 10 and 30 mille-seconds. There are also fuze-type or suspended igniters which work by a flash of flame. Sometimes, the igniters are cupshaped, but work on the same principle of intensive flash of fire to ignite the propellant at the instant the firing trigger is depressed.

Fin Assembly. The function of the fins is to provide stability in flight, prevent tumbling and insure head-on impact. Fins may be of fixed or folding type. The action of the air on the fins restores balance and causes the rocket to move in a head-on direction. Fins on rockets are sometimes provided with gyro-controlled surfaces in which case the rocket becomes a guided missile. The tendency of these controls is to produce wandering of the rocket about a smooth line of trajectory. A bent fin will produce excessive yaw during burning so that the thrust is in the wrong direction. Fin-stabilized rockets usually rotate slowly due to slight differences in rocket symmetry. Spin-stabilized rockets rotate rapidly and have more tendency to yaw—which is the tendency of the nose to revolve about the line of trajectory, resembling a spiral-weaving action of the projectile. Spin-stabilized rockets, however, are more accurate than the fin-stabilized type.

14. AIRCRAFT ROCKET TYPES, MODELS, AND DATA

Principal Types

2.25" Sub-caliber Rocket, SCAR, Fin-stabilized Practice Rocket. This is supplied in two types to match the trajectories of the 5.0" HVAR and 5.0" AR respectively. This was formerly accomplished by providing a light and a heavy head. At present the weight and the head are kept constant and the motor varied. The 2.25" rocket head MK 1 and modifications, or MK33 and modifications, are issued with the 2.25" rocket motor MK 10 and modifications (fast motor) to match the trajectory of the HVAR; and with the 2.25" rocket motor MK 12 (slow motor) to simulate the 5.0" AR.

3.5" aircraft rocket, AR, fin-stabilized. The 3.5" rocket head has been manufactured in TNT, FS, WP and special loaded models. However, the only types currently issued through Army ordnance channels are the solid shot MK 2 and MK 8.

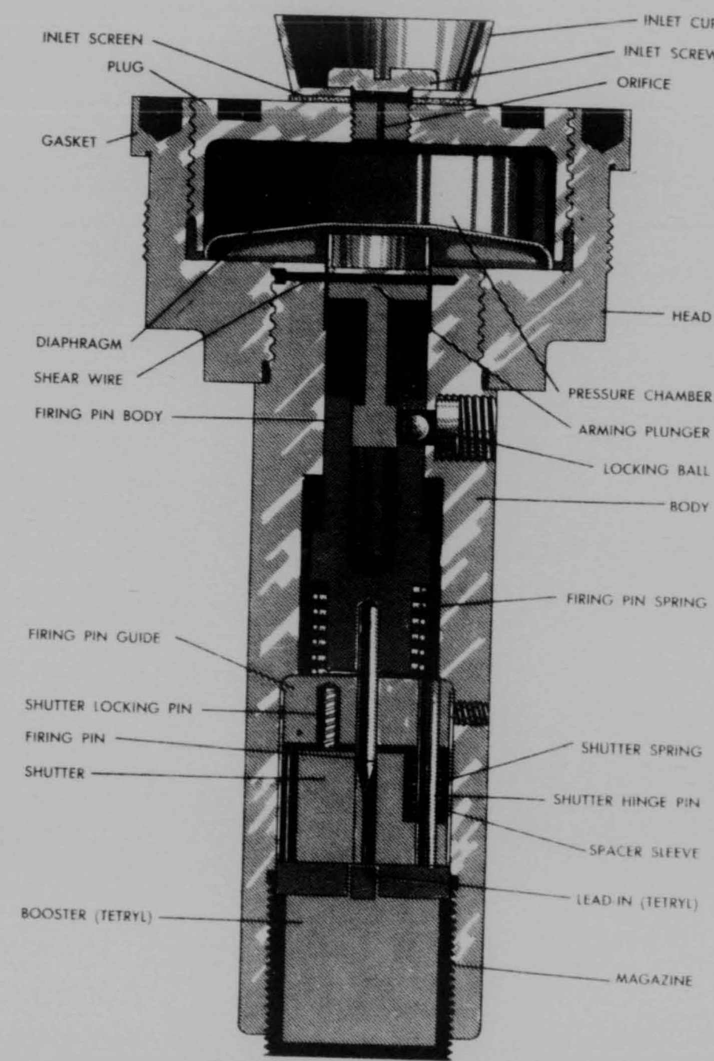

Figure 7—33. Base Fuze, MK 157 (PIR).

3.5″ aircraft rocket motor with 5.0″ head, fin-stabilized. This, as the name implies, is merely the 3.5″ rocket motor bushed to receive the standard 5.0″ AR rocket head. The various modifications of the 3.5″ rocket motor MK 7 are in details of nozzle construction.

5.0″ high-velocity aircraft rocket HVAR, fin-stabilized. The 5.0″ rocket heads MK 5 and modifications and MK 6 head and modifications essentially are the same except for details of the base-fuze assembly. The 5.0″ rocket motors differ principally in the fin assembly; MK 1 and MK 2 Mod. 0 had fins welded to the motor, MK 2 Mod. 2 had fins attached to a sleeve which is assembled to the motor as issued; and MK 2 Mod. 3 has fin issued separately.

5.0″ aircraft rocket, AR, fin-stabilized. The 5.0″ rocket head MK 1 on this rocket can be distinguished from the HVAR by the internally threaded motor adapter.

11.75″ AR (Tiny Tim)

This model uses a 500 S.A.P. bomb (AN-M58) filled with TNT and wells for 3, MK 163 base fuzes in the head. It has no nose fuze. The reason for using thre base fuzes is for positive detonation of the TNT filler. The MK-2 11.75″ H.E. head is used with the MK 1 Mod 3, 11.75″ rocket motor only. The MK-4, 11.75″ high explosive head (Tiny Tim) is used with the MK-2, 11.75″ rocket motor, only. The MK-2 and MK-4 heads are not interchangeable due to the size of the threads. The MK-4 head will have finer threads than the MK-2. The total weight of the 11.75″ Tiny Tim is 1280 lbs. and it is approximately 10 ft. long.

Painting

In general, rocket motors are painted olive drab. The colors used for rocket heads are as follows:

High-explosive. Painted lusterless olive drab; marked in yellow.

Chemical (gas). Painted lusterless grey; marked in green.

Chemical (smoke). Painted lusterless grey; marked in yellow.

15. ROCKET FUZES

Rocket fuzes are components of the head, but are usually taken up separately because of their importance, intricate nature, and many types. The function of the fuze is to explode the burster charge in the head. Rocket fuzes

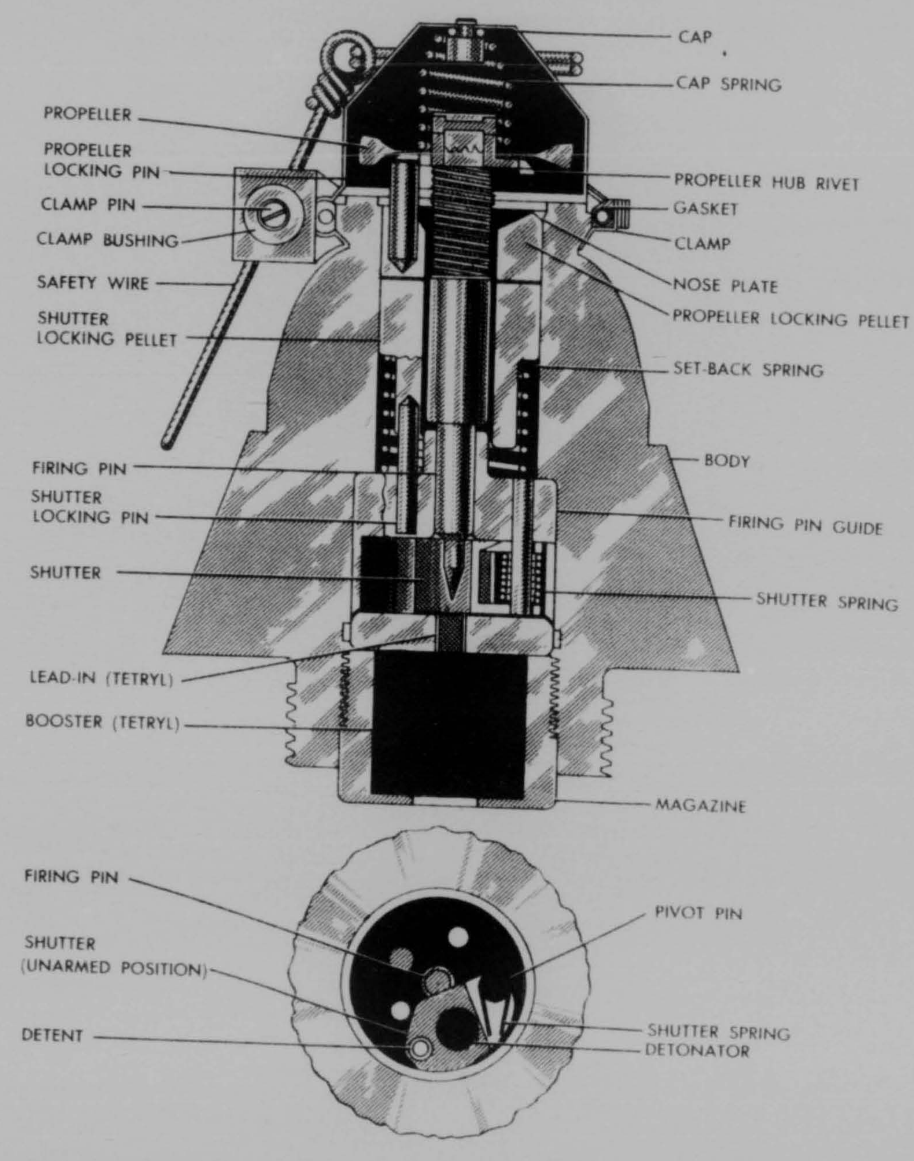

Figure 7—34. Air 8 Fuze.

THIS PAGE IS DECLASSIFIED IAW EO 13526

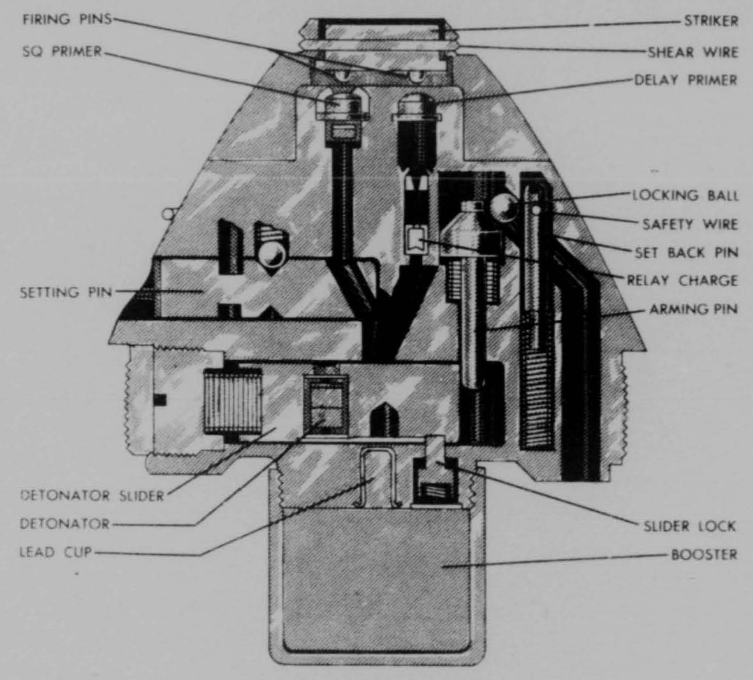

Figure 7–35. PD Fuze M4A2 Schematic Section.

at present are either nose or tail fuzes, though transverse or side fuzes could be used if the rotation of the rocket were taken into consideration. Except for minor differences, rocket fuzes are similar to bomb fuzes. Rocket fuzes are designed to arm where the set back is small and for this reason are generally more sensitive than bomb or artillery fuzes. Base fuzes use pressure developed by the burning gases for arming. The pressure acts through a piston causing it to move so the firing pin may line up with the primer after set back ceases.

Normally, since aircraft follow closely the trajectory of their rockets, rocket fuzes travel a great distance before they are armed, usually not being completely armed until set back ceases at the end of the burning period. This is very important when firing at close ranges, as in the case of air to air combat.

Base Fuzes

No further preparations are necessary than to ascertain that the base fuze is present and in tightly; inasmuch as no safety wire is used, **a rocket designed for a base fuze must not be fired without one**, for a premature explosion of the rocket head would then occur before the rocket even left its launcher. The principal types of base fuses are the MK 157 with 0.020 second delay and MK 159 with .015 second delay. They are known as "pir" fuzes or pressure arming, impact operated. Other than the difference in delay the fuzes are identical. (Figure 7-33)

The functioning mechanism of the MK 157 and MK 159 fuzes is contained in two pieces, the head and the body. The head contains a gas chamber formed by the plug, and the diaphragm gases from the rocket motor are permitted to flow slowly into the gas chamber

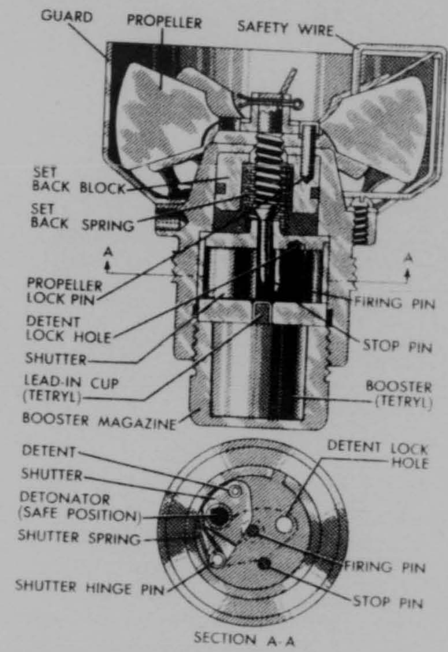

Figure 7–36. Nose Fuze MK 137 (AIR).

through an aperture in the inlet screw. When the pressure in the chamber reaches about 250 pounds per square inch, after about half the burning time of the propellant, the diaphragm collapses shearing a shear wire; this allows movement of a plunger and release of cockingball. After acceleration is over, the firing pin has been withdrawn from a shutter, the shutter has moved forward, and upon disengagement of the shutter cocking pin, it is swung into the armed position with the delay detonator in line with the firing pin.

Other base fuses are the M 146 (air), M 400 and M 401.

Nose Fuzes

The present most commonly used nose fuze is the MK 149. In the unarmed position, the firing pin is screwed down along side the detonator shutter holding it to one side. The propeller, or vane, attached to the firing pin is prevented from turning by the propeller locking pin attached to the propeller locking pellet. The cap on the nose of the fuze is held tightly in place on the gasket by a clamp assembly held together by a safety wire.

When the round is fired, the arming wire pulls free, releasing the clamp assembly which falls apart. The cap spring throws off the cap exposing the propeller. At the same time, acceleration retracts the propeller locking pellet releasing the propeller.

The fuze may be fired safe if the arming wire is released so that it stays with the fuze. In this case, the base fuze will operate giving a slight delay explosion.

Other nose fuzes are the M 4 A 2, MK 137, MK 149, and M 81.

Storage

Fuzes should be stored, separate from the other components, in dry indoor storage in a well-ventilated magazine, protected against the direct rays of the sun, excess moisture, and heat. They require especially careful handling to prevent shock. The individually, hermetically-sealed packing cans must not be opened prior to use.

16. INSPECTION OF ROCKETS AND GENERAL PREPARATIONS FOR FIRING ROCKETS

Components are removed from packings and inspected for serviceability. Rocket heads should be inspected to see that the fuze and adapter threads are undamaged, that the nose-fuze well contains an auxiliary booster and that heads adapted for base fuze have the base fuze assembled. Motors should be inspected to see that they are free from dents, threads clear, closing discs and short circuit clips are effectively in place, that fins are not bent and that lugs appropriate to the launcher are tightly secured in place. Fuzes should be inspected as specified for that particular fuze. Special instructions issued for particular fuze and rocket and temperature requirements should be checked.

The shipping plugs and caps are removed and the motor and head assembled. It is tightened with sharp wrenches. If necessary, fin is assembled to motor.

THIS PAGE IS DECLASSIFIED IAW EO 13526

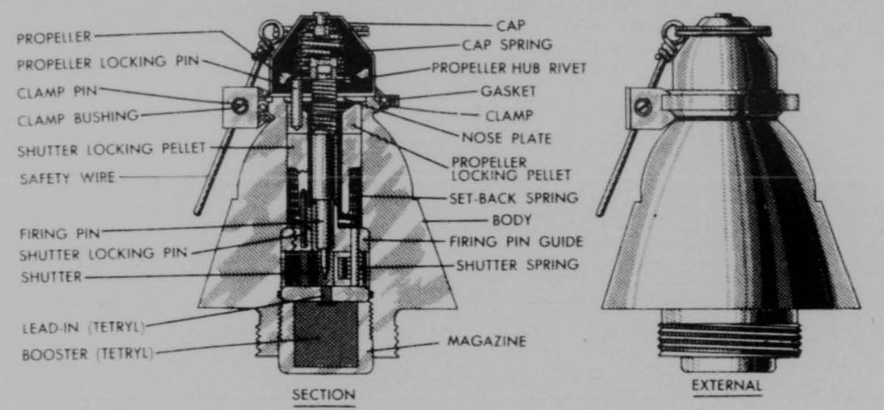

Figure 7—37. Nose Rocket Fuze MK 149.

The fuze is assembled to head as prescribed by special directions for the particular fuze.

All electrical connections and launching equipment are checked. They are tested with circuit testers.

The shorting clip is removed from fuse after rocket is loaded on launcher.

All safety regulations must be obeyed.

17. PRECAUTIONS

Unnecessary personnel must be kept away.

A safety man familiar with all safety regulations should be on hand to observe preparation for firing. Personnel must obey any safety orders issued.

Personnel working on rockets should stand on side of rocket—never in front or rear of rocket.

Rockets having base fuze must have base fuze assembled properly. If rocket is fired with base fuze missing rocket will detonate on launcher when fired.

All necessary electric circuit tests must be made prior to reloading rockets on launchers.

18. MAINTENANCE OF ROCKETS

Rockets and components must be regularly inspected and maintained in serviceable condition at all times. Proper paint should be applied, rust-preventative grease authorized for use should be used. Motors should never be stored with heads. Proper records should be maintained on incoming and outgoing shipments. Stock records must reflect accurately at all times particulars on rockets on hand, including lot numbers and place of storage. Special maintenance instructions for each component should be followed and proper records kept. Personnel must have thorough knowledge as to what is permissible in maintenance. Prompt and proper action must be taken in case reconditioning, renovation, or destruction is required. All safety regulations applying to maintenance and storage must be strictly followed such as adequacy of fire extinguishers, nonsparking tools used, safety shoes worn, and compliance with all other regulations required.

SECTION V—GLOSSARY OF TERMS

Acceleration. Rate of increase in velocity, measured in G's.

Airfoil. A thin streamlined surface used for wings, rudders, or flaps.

Air Resistance. The resistance produced by the atmosphere toward any object moving rapidly through it.

Air Sounding. Measurements of air conditions at high altitudes by a radio sound or similar equipment.

Air Stream Engine. A reaction motor that depends on the atmosphere to support combustion or increase the mass of the jet.

Ambient Temperature. Surrounding air temperature.

Ammunition. Munitions and their necessary components which contain an explosive or chemical filler designed for use in combat.

Angle of Attack. Attitude that aircraft assumes in flight.

A.R. Aircraft Rocket.

Area Ratio. The ratio between the mouth area and throat area of a rocket nozzle.

Armor-piercing. Projectiles with a hardened steel element designed to pierce armor plate in vehicles or planes.

Athodyd. Continuous duct engine.

Atmosphere. Air from sea level to 18000 feet.

Augmentor. Device used for increasing pressure, velocity of thrust.

Axial Flow Compressor. A rotary air compressor using propeller-like blades through which the air flows parallel to the shaft.

Axis of Thrust. An imaginary line drawn through the center of the jet of a rocket motor, along which the thrust or reaction of the motor is directed.

Basic Color Scheme. Term used in reference to identifying types of ammunition by colors. For example, high explosive ammunition is painted olive drab.

Black Powder. A low explosive made of sulphur, charcoal, and saltpeter. Used widely as a propellent charge.

Blast Chamber. The chamber in which a propellant is burned in a rocket motor of jet engine.

Body. As used in terms of military ammunition, the body is generally the case of any ammunition that contains the explosive or chemical filler, also the part to the rear of the bourrelet.

Booster Rocket. An auxiliary rocket device with a large thrust and brief firing time used to bring rocket or aircraft up to flying speed.

Bore Sighting. Procedure of aligning axis of bore with sights.

BSDL. Bore sighting datum line.

Burster. An explosive element found in chemical ammunition which bursts the shell enabling the chemicals to be dispersed.

Bursting Charge. This is the explosive filler in a bomb or shell. TNT or amatol are bursting charges.

Cable. Connection of rocket between ignitor and plug.

Catapult. A device for launching a rocket or airplane with high initial speed.

Cavity. As used in ammunition a cavity is any place in a bomb, projectile, or mine that is used to receive a fuse or tractor composition.

Center of Gravity. The point at which all the mass of any flying body appears to be concentrated.

Centrifugal Compressor. A rotary air compressor similar to a centrifugal pump in which air is thrown radially outward by vanes.

Ceramic Liner. A porcelain heat resistant lining for a combustion chamber.

Chuffing. Extinguishing and spontaneous reigniting of a grain of powder.

Chamber Pressure. Pressure shown by a gauge connected to the combustion chamber during firing.

Chemical Fuel Motor. A true rocket motor using propellants supplying their own oxygen (as opposed to air stream engines or ram jets which obtain their oxygen from the air).

Chugging. Irregular combustion due to incorrect mixture or poor chamber design.

Chute Boot. The parachute container of a sounding rocket.

Clinometer. Instrument used for measuring vertical angles accurately.

Closing Plug. A part of many types of ammunition that is added after the body has been filled with a high explosive. It is also used to protect fuze cavities until the time the fuze is actually inserted for use.

Combustion Chamber. An alternate name for blast chamber.

Compressibility Burble. An unsteady type of airflow around an air foil operating close to the speed of sound marked by reduced useful life and increased drag.

Concentric Tanks. Fuel or propellant tanks nested one within the other with a common central axis.

Construction Weight. The weight of tanks, motor, pumps, controls, landing gear, et cetera, of a rocket exclusive of fuel; an alternate name for structural weight.

Controlled Rocket. A rocket which has a guided mechanism capable of controlling the direction of flight.

Coolant. Any material used to cool a rocket combustion chamber or nozzle.

Cordite. A double base powder.

CV Aircraft. Carrier-borne aircraft of certain types.

DBT. Dibutylpthalate, an oily viscous liquid inert as an explosive.

Delayer. A substance mixed with the propellant of a dry-fuel rocket to decrease the rate of combustion.

Delay Train. A means provided in ammunition to delay the detonation. Black powder is commonly used.

Demolition. Destruction caused by blast of HE ammunition.

Depressor. Substance used to depress flash of propellants.

Detonation. The rapid explosion of a high explosive, or an explosive train.

Detonator. A highly-sensitive explosive used in an explosive train. It is usually initiated by a firing pin or striker. Azide is often used for this.

Dipropellant. A combination of two substances used as a rocket fuel.

Displacement. Swings rocket from carried position into firing position.

Dissociation. Decomposition of the burned gases in a combustion chamber at high temperature producing a loss of heat energy.

DNT. Dinitrotoluene which is a neutral solid used primarily as a stabilizer because it reduces hygroscopicity.

D.P.A. Diphenylamine, a stabilizer which acts by combining with nitrous fumes or exides of nitrogen evolved in deterioration of nitrocellulose.

Drag Coefficient. A factor representing the relative air resistance of a particular shape of airfoil.

Drop Unit. A booster rocket which can be jettisoned after exhaustion of its propellants.

Dud. Any explosive or chemical ammunition that had failed to function under normal conditions.

Dynameter. Device by means of which force is applied, or by which kinetic energy is converted into propulsion.

Dynamometer. A device for indicating and recording the thrust of a rocket motor during a test, also called a reaction balance.

Escape Velocity. The velocity at which an object would escape the gravitational attraction of a given astromical body. The escape velocity of the earth is 6.664 miles per second.

Explosive Train. The arrangement of explosives for a small charge of sensitive explosive to a large charge of comparatively insensitive explosive. Detonator booster, then bursting charge, in an arrangement of an explosive train.

Explosion. The sudden generation of a large volume of highly heated gases with the resultant pressures, and the fragmentation.

Explosive. Any mixture, or substance that upon application of heat or shock, suddenly undergoes a chemical change (from a solid to a gas), that produces a great quantity of heat and a large volume of gases.

Explosive Filler. The bursting charge of any type of ammunition.

External (or Ballistic Efficiency). The ratio between the energy usefully employed in propulsion and the kinetic energy developed by the jet; same as mechanical efficiency.

Filler. Contents carried in an ammunition container. They may be explosive, chemical, or inert.

Fill Hole. The orifice through which liquid fuels are loaded into a rocket tank.

Final Mass. The mass of the rocket at the end of flight.

Fins. A component part of some ammunition added to give stability in flight, preventing rotation. Bombs, rockets, and mortars have fins.

Fins. Fixed rudders on a rocket to help give it direction.

Fin-stabilized Rocket. A rocket which does not rotate in flight but is stabilized by means of fixed fins or vanes.

Flaps. Movable rudders, either attached to the fins or placed in the jet of a rocket, to direct the flight.

Flare. The bell-shaped inner curve of some types of rocket motor nozzles.

Flare Angle. See Taper.

Flow Meter. A device for measuring the rate of flow of liquids or gases.

FPS. Feet per second.

Fragmentation. The actual shattering of an item of ammunition by the bursting charge. It is the final result of the explosive train.

Fragments. Pieces of metal that are shattered at high velocity as a result of the bursting of the body or casing of ammunition.

Free Flight. The portion of a rocket's flight which follows the combustion of the fuel or the turning off of the rocket motor.

Free-flight Angle. The angular direction of a rocket with respect to the earth at the beginning of free flight.

Free Rocket. A rocket which has no guiding or flight-control devices other than fixed tail or fin surfaces.

Fuel. The combustible component of a rocket propellant. It often includes the oxidizer as well.

Fuel-weight Ratio. The ratio of the weight of a rocket's fuel to that of the empty rocket without fuel; also called fuel-structure ratio. It is equal to the mass ratio minus one.

Fuze. A mechanical device used to initiate the explosive train at the time desired and under proper circumstances. There is no definite type of fuze for all ammunition.

Fuze. Either nose fuze or base fuze of rocket. Function is to allow safety prior to arming and finally to detonate rocket on impact or time.

Fuze Cavity. Any opening provided at time of manufacture for the purpose of receiving a fuze. The fuze may or may not be assembled with the ammunition it is designed for.

G. Symbol for gravity, the unit of acceleration equal to 32.2 ft. per second.

Gantry. An inverted U-shaped frame with hoisting equipment and platform for working on rocket head and instruments prior to vertical launching.

Gapa. Ground-to-air pilotless aircraft; a rocket interceptor.

Gogetter. A control mechanism for large military rockets or robot planes especially one intended automatically to guide the rocket to target.

Grain. Shaped particle of powder propellant.

Grain. 1/7000 part of pound.

Grid. Trap, supports powder grain before and after burning.

Gyro Control. A gyroscopically-operated device for guiding a rocket in flight.

Harmonization. Procedure of aligning target of projectile with a sight at specific range.

HE. High Explosive.

Head. That part of rocket containing payload.

High Explosive. An explosive functioning with high-order detonation.

High-order Detonation. A complete and instantaneous detonation.

Hull. The outer casing of a large projectile.

HVAR. High-velocity aircraft rocket.

Ideal Rocket. A rocket constructed to such a fuel-weight ratio that it will reach the velocity of its own jet in space. This ratio would be 1 to 1.72, the larger number of referring to the fuel.

Igniter. A device such as a fuze for igniting a rocket motor.

Ignition Train. A series of low explosives provided for the specific purpose of propelling a projectile into flight. The train usually consists of the primer and propellant. The rapid expansion of the gases created from the burning of the propellant cause the flight of the projectile.

Impact. A term used in reference to ammunition designating the actual instant a projectile hits its target. Impact fuze is one that is detonated by impact alone and has no time-delay element.

Impulse. The total output of a jet motor in a given shot; equivalent to average reaction multiplied by time.

Impulse-weight Ratio. The ratio between impulse (reaction multiplied by total firing time) of a jet motor and the total loaded weight, including auxiliaries.

Incidence. Angle of mounting of wing, usually at about 3 degrees over horizontal.

Inhibitor. A strip of fire-resistant plastic that is bonded to the external surface to reduce degressive burning substances such as DNT which reduces hygroscopicity.

Initial Mass. The mass of the rocket at beginning of flight.

Injector. The inlet device which admits propellants to a rocket motor.

Inlet Ports. The openings or nozzles through which propellants are injected into the rocket motor.

Ionosphere. Altitudes above 87000 feet or above stratosphere extending to 200 miles above earth, 96 per cent of air is below ionosphere.

Japee. A jet engine or an aircraft driven by jet propulsion.

Jato. Apparatus for producing jet-assisted take-off or an aeroplane so equipped.

Jet. The stream of gas effected by a reaction motor.

Jet-assisted Take-off. An airplane take-off accelerated by the use of a thrust or rocket or jato.

Jet Engine. An airstream engine; a reaction motor equipped to use oxygen of the air as an oxidizer; types, ram jet, turbo jet, impulse jet, thermojet, and continuous duct engine known as athodyd.

Jet Motor. A self-contained or true rocket motor; a reaction motor supplied with oxygen as one of its propellants, as contrasted with the jet engine or airstream engine or ram jet engine.

Jet Propulsion. Rocket power: propulsion by thrust developed by ejecting a jet of rapidly moving gas or other substance through a nozzle.

Landing Gear. Equipment usually consisting of a parachute and release mechanism for bringing a rocket gradually to earth after a shot.

Launching Angle. The angle measured from a horizontal plane, at which a rocket is inclined at launching.

Launching Rack. A fixed rocket launcher.

Launching Rails. Rail type launching device.

Launching Trough. Trough type launching device usually semicircular in section.

Lead Azide. An extremely sensitive high explosive used in primers or detonators along with other explosives to initiate an explosive train. It is very sensitive to fire, but not impact alone.

L/D Ratio. The ratio of length to diameter of a rocket-motor combustion chamber.

Liquid-fuel Propellant. Liquid mixture usually hydrocarbons such as kerosene, alcohol, gasoline, liquid hydrogen.

LOS. Line of Sight.

Low Explosive. A relatively slow-burning explosive which does not ordinarily detonate, for example FNH powder.

Lox or Loxygen. Liquid oxygen.

Lug Bands. Bands equipped with appropriate fittings which are attached to the motor tube, and used to suspend the rocket from rail or post type of launchers. Two types of lugs are button type, and tunnel type.

Mach Number. The ratio of the velocity of a rocket or jet to that of sound in the medium being considered.

Mach Waves. Nodes or standing waves in a rocket jet caused by reflection of the jet from the surrounding air.

Mass Ratio. The ratio between the total mass of the rocket ready to shoot and the final mass of the empty rocket.

Mechanical Efficiency. The ratio between the energy usefully employed in propulsion and the kinetic energy developed by the jet (same as ballistics or external efficiency).

Mechanical Time Fuze. Any fuze whose action is controlled by clocklike mechanism. Such fuzes may be found on bombs or artillery shells. Usually they will provide for several seconds delay in the operation of the fuze.

Mercury Fulminate. Another extremely sensitive high explosive used in detonators. It is very sensitive to fire, or impact from a firing pin.

Meteorgraph. An apparatus for determining or recording atmospheric data.

Metering Orifice. An apparatus for determining or recording atmospheric data.

Mono Propellant. A propellant consisting of a single liquid which contains both fuel and oxidizer either combined chemically or a mixture.

Motor. The device that provides thrust for a rocket; alternatives; jet motor, rocket motor, thrust motor, reaction motor; includes propellent charge and support, cable and plug, motor tube and nozzles.

Motor Head. The upper portion of a rocket motor, usually containing the propellent injection parts and the igniter.

Motor Tube. Seamless threaded at one end to receive the head.

Mouth. The large end of the expansion nozzle.

Mouth Area. The cross-section of the nozzle mouth.

Multi-nozzle Motor. A rocket motor with more than one nozzle.

NACA. National Advisory Committee for Aeronautics, Washington, D. C. in charge of research data for use in the design and operations of missiles to be developed, by the Army, Navy, and Air Force.

NDRC. National Defense Research Committee.

Nondelay Fuze. A fuze designed to burst a projectile outside its target before penetration or ricochet.

Nozzle. The orifice and expansion device through which the jet is ejected from a rocket motor.

Nozzle Coefficient. The amount experimentally determined by which the shape of a specific nozzle increases the thrust of the motor.

Opacifier. Substance used to absorb the radiation produced by the burning surfaces. Should the powder grain absorb these radiations, the absorbing area becomes heated and decomposition or breakage of the grain is liable to result.

Oxidizer. The oxidizing component of a rocket propellant such as liquid oxygen, hydrogen peroxide, potassium chlorate.

Parachute Release. An automatic device for ejecting a landing parachute from a rocket.

Parallel Tank Rocket. A rocket with parallel, cylindrical fuel tanks.

Payload. The useful load carried by the rocket in addition to its necessary structural weight and fuel.

Pentolite. A high explosive of an insensitive nature used as a filler. It is a mixture of TNT and PETN. Many rockets have a pentolite filler.

Photoflash Bomb. One type of pyrotechnic dropped from aircraft, which produces a brilliant flash of light sufficient for photographic purposes.

Plasticizer. A material used in a powder to hold the ingredients in close bond.

Plug. Connector of cable to aircraft electrical circuit.

Post. Rocket carried under post or posts by means of fittings on the rocket motor tube.

Powdered Flight. The portion of a rocket's flight during which the rocket motor is in operation.

Primer. A device used to ignite a propelling charge. It is fired by shock from a firing pin or striker.

Projected Area. The maximum cross section of a rocket hull when viewed head-on.

Propellant.-A propelling agent; the low explosive which upon ignition propels a projectile from the weapon.

Propellants, Composite. Powders of at least 2 components such as equal amounts of ammonium picrate and sodium nitrate with an added plasticizer.

Propellants, Liquid. Types kerosene, gasoline, alcohol and other hydrocarbons.

Propellants, Solid. Ballistite, smokeless powder, cordite, gun powder.

Propellent. (adjective) Able to propel.

Propelling Charge. A definite quantity of low explosive used to propel a projectile. The charge is ignited by the primer turning to a gas.

Proving Stand. An equipment for testing or proving rocket motors also known as test stands.

PSF Ratio. The payload-structural-fuel ratio.

Pulse Jet. An intermittent jet.

Pyrotechnic Fuel. A solid propellant which supplies its own oxidizer as part of the mixture as in the case of gun-powder.

Radio Sonde. A form of meteorgraph transmitting its indications automatically by radio; used in high altitude air soundings.

Rato. Rocket-assisted take-off, an early use was on B-25 planes.

Reaction. The recoil or "kick" produced by the jet of a reaction motor which provides the propulsion force.

Reaction Motor. The general term for all types of jet-propulsion motors and engines.

Reflector Plate. Transparent mirror of optical sight on which reticle image is projected.

Regenerative Motor. A rocket motor equipped with a cooling jacket through which the fuel flows on its way to the injector, thus carrying the waste heat back into the blast chamber.

Regulator. A device for regulating the flow or pressure of a gas.

Relative Wind. Direction of wind with respect to direction of flight of the rockets.

Resonator. An impulse jet of intermittent type.

Reticle. That part of a sight which has a ring or bead cut out of thin metal plate or etched on the back of a mirror in an optical sight.

RPLCS. Rocket-propelled landing-craft support; applied to rocket-propelled boats used to lay smoke screen prior to amphibious landings.

Rocket. A projectile driven by jet propulsion.

Rocket Field. A proving field or area for rocket experimenting.

Rocketor. A rocket engineer or rocket experimenter.

Rocketry. The field of rocket theory, development, research, and experimentation.

Rudder. A steering device either attached to fixed fins or placed in the jet of a rocket to direct the flight.

Rupture Disc. A thin disc of special metal used as a safety valve.

Safety Groove. A groove on the motor of a rocket near the head to weaken it so that

it would break at this point in case of excess pressure.

Safety Valve. A valve placed in an oxygen or pressure tank to relieve the pressure before it reaches the bursting point of the tank.

Scar. Subcaliber aircraft rocket.

Sectional Density. The weight of a rocket divided by its maximum cross-section used in estimating air resistance.

Shear Wire. Wire used for safety purposes which shears on functioning of rocket.

Shock Waves. Sound waves set up by an object moving at supersonic speeds, causing increased energy losses.

Shot. A rocket flight.

Shroud. A curved stabilizing or control surface at the tail of the rocket.

Skin Friction. The drag of an object moving in air caused by the air on the surface.

Slant Range. Airline distance from airplane to target; useful in dive rocketry and dive bombing.

Socket. Receives the plug of the rocket.

Solid-Fuel Rocket. A rocket propelled by a solid or dry pyrotechnic propellant.

Solid Motor. A nonregenerative liquid fuel rocket motor.

Solventless Process. Relatively dry process of manufacture of propellants.

Solvent Process. Liquid process of manufacture of propellants usually with ingredients containing nitroglycerine, alcohol, and acetone.

Sounding Rocket. A high-altitude rocket carrying air-sounding equipment.

Spacer. A device for separating sections of a rocket or to act as an insulator.

Spinner. A winged device like the rotor of an auto gyro, used instead of a parachute to bring a rocket gently to earth.

Spin-Stabilized Rocket. A rocket designed to rotate rapidly during flight thus obtaining stability in the same manner as an artillery shell.

Stabilizer. Fin member to produce stability of flight.

Stabilizer (chemical). Substance added to powder to aid in preventing decomposition usually by absorbing gaseous products of slow decomposition.

Step Rocket. A rocket consisting of several sections or "steps" fired successfully each step being jettisoned when its fuel is exhausted.

Stratosphere. Altitude from 35,000 feet to 87,000 feet.

Super-Sensitive Fuze. A fuze which is designed to function upon impact with a very light target.

Tandem Tank Rocket. A rocket with cylindrical propellant and pressure tanks placed end to end; a single-stick rocket.

Taper. The angle.

Test Stand. Same as proving stand.

Thermal Efficiency. The ratio of the kinetic energy developed by the rocket jet to the thermal energy content of the fuel.

Thermal Jet Engine. A type of airstream engine containing a rotary air compressor to provide air under pressure to sustain combustion.

Third Law of Motion. Sir Isaac Newton's statement of the principle upon which the reaction motor works "To every action there is always an equal and contrary reaction; the mutual actions of any two bodies are always equal and oppositely directed."

Throat. The narrowest part of a rocket nozzle.

Throat Area. Cross-sectional area of the narrowest part of the nozzle.

Thrust. The push produced by a jet or rocket motor.

Thrust Augmentor. A funnel-like device for guiding the surrounding air into a rocket jet thus producing suction which increases the thrust.

Tracker. A mechanism for observing or controlling a flying rocket from the ground, or the man operating such a device.

Trajectory. The curve which a body as a missile describes, influenced by the force of gravity.

Trap Plate. Grid or support for powder grain during burning.

Tropopause. Thin layer of upper air between troposphere and stratosphere.

Troposphere. Upper air from 18,000 feet to 35,000 feet.

True Rocket Motor. A self-contained, or chemical-fuel motor.

Turbo Jet. A thermal jet engine in which the compressor is driven by a gasturbine.

Valve Man. The operator who actually fires a liquid fuel rocket.

Velocity, Hypersonic. Velocities above 5,000 miles per hour.

Velocity, Subsonic. A velocity less than that of sound.

Velocity, Supersonic. A velocity greater than sound.

Velocity of Sound at Sea-Level. 1,100 feet per second or 750 miles per hour; lower at higher levels.

Venturi. The nozzle shape which consists of a cone-shaped restriction to the throat or narrowest section, and then expands in a cone shape to the exit.

VJ. The jet velocity of reaction motor.

War Head. The explosive section of a military rocket.

Weight-Fuel Ratio. The ratio between the structural weight and the fuel weight.

Weight Ratio. Same as mass ratio.

Wetted Surface. The total external surface of a streamlined hull exposed to air friction.

White Cellulose. Gun cotton.

Windage. Allowance for effect of wind on trajectory.

Zero Launcher. Launcher which releases rocket within movement of one inch or less.

CHAPTER 8—STORAGE, HANDLING, AND INSPECTION

SECTION I—STORAGE OF AMMUNITION AND EXPLOSIVES

1. GENERAL

In order that ammunition and explosives be safely and adequately stored, they must be stored in conformance with accepted principles of ammunition storage. These principles involve:

- Mixed storage regulations
- Quantity distance regulations
- Fire hazards
- Stacking and piling

2. MIXED STORAGE REGULATIONS

Purpose

Under normal storage conditions (when ammunition is stored within a standard ammunition magazine), the mixed storage regulations govern what items of ammunition or explosives may be stored together within a single magazine. Under field conditions (when ammunition is stored out of cover), the mixed storage regulations indicate what items of ammunition or explosives may be stored together within a single field storage unit.

Theory

Prior to World War I, mixed storage regulations were nonexistent because the few items of military ammunition and explosives that were used at that time had relatively the same characteristics and thereby presented no mixed storage problem. World War I in-

XVII. Black powder ammunition and bulk black powder	O														O	O	X	O
XVIII. Photoflash bombs	O														O	O	O	X

[1]An "X" at the intersection of a horizontal row and a vertical column denotes that all items in the two groups may be stored together.
[2]An "O" at the intersection of a horizontal row and a vertical column denotes that all items in the two groups may be stored together if the explosive content of the items of the two groups stored together in one magazine or revetment does not exceed 1000 pounds.

Figure 8–1. Combination Storage Chart.

troduced, among other new types of ammunitions, chemical ammunition. When, after World War I, large stock piles of military ammunition and explosives were accumulated into stock piles, serious fires and explosions taught the lesson that many of these new items of munitions were not compatible with each other and had to be segregated for storage purposes.

Result of an Explosion

If the explosion of one type of ammunition is likely to cause the explosion of another type, the two types should never be stored together. An example involves dynamite and fragmentation bombs. An explosion involving fragmentation bombs would set loose large quantities of high velocity missiles while a dynamite explosion would result in shock or concussion. Were they to be stored together, the dynamite would be exposed to missile hazard; should the bombs detonate, the missiles being propelled by them would in turn detonate the dynamite. Were the situation reversed and the dynamite initiated, the shock or concussion from the dynamite would through sympathetic detonation, set off the bombs. Were this not the case, the bombs themselves could be propelled and become missiles in themselves.

Ease of Deterioration

An item of ammunition which does not tend to deteriorate readily should never be stored with one that does, for example, bulk smokeless powder and TNT. Bulk powders are very susceptible to spontaneous combustion because of deterioration, whereas TNT seldom deteriorates even under extreme storage conditions. If TNT were to be stored with the bulk powders, it would be necessary to assume that the TNT was equally as subject to spontaneous combustion because of deterioration. Were the powder to initiate, the TNT would also be lost simply because of the fact that it was stored with an item of ammunition which is more susceptible to deterioration.

Sensitivity of Initiation

Items of ammunition which are of an insensitive nature should never be stored with items of ammunition which tend to initiate readily, for example, TNT and blasting caps. TNT is very insensitive whereas blasting caps are of the other extreme. Were the TNT to be stored in the same magazine with the blasting caps, it would be necessary to assume that the TNT was just as sensitive as the caps, in that should the caps initiate, the TNT would in turn be set off.

Type of Packing

Items of ammunition packed in metal crates must not be stored in the same magazine with items which come in wood boxes. This is primarily a fire consideration in that should the wooden packing become ignited, the ammunition in the metal crates would be exposed to that fire.

Action in Case of Fire

If two items of ammunition require a different means of extinguishing them should they start burning, they should not be stored together. An example is white phosphorus filled items and small-arms ammunition. Burning small-arms ammunition is extinguished by means of water spray or fog. To extinguish white phosphorus, it is necessary to flood it with water. The application of spray or fog would tend to accelerate greatly the rate of burning as well as to cause the phosphorus to spread about the area.

Quantity of Explosives per Unit

Types of ammunition having a small quantity of explosive in a single item should not be stored with ammunition which has a large quantity of explosive in a single item, for example, demolition bombs and armor-piercing bombs. The demolition bomb contains approximately 50 per cent explosive filler whereas the armor-piercing bomb contains from 2 per cent to 15 per cent explosive filler. If the two items are stored together the armor-piercing bombs would needlessly be exposed to the large quantity of explosives in the demolition bombs.

Inert items of ammunition should never be stored with items of ammunition containing an explosive filler. Should the loaded items detonate, the inert items would be needlessly lost.

Application of Mixed Storage Regulations

The mixed storage regulations are in the form of ammunition mixed storage charts, which vary for different types of installations.

The chart shown in Figure 8-1 is particularly adapted for use on posts, camps and stations for it is designed to fit the needs of bases storing small quantities of ammunition and explosives and having limited storage facilities. This chart is also a great deal less restrictive than other charts. In cases where the actual explosive weight of the material being stored is less than one thousand pounds the chart permits a broad deviation from mixed storage principles.

Compliance with this chart is required on the majority of Air Force bases.

The chart shown in Figure 8-2 is designed primarily for use at ammunition depots or installations having large and varied stocks of ammunition supplies and extensive storage facilities.

3. MIXED STORAGE REGULATIONS UNDER FIELD CONDITIONS

General

Under field conditions, ammunition and explosives are stored in what are called "field storage units," rather than in standard ammunition magazines. A field storage unit is simply an outdoor area in which a specific type of ammunition is stored.

Field Storage Groups

For the purpose of determining what items of ammunition may be stored together within a single field storage unit, all items of ammunition and explosives have been divided into what are called "field storage groups," of which there are four.

Field Storage Group I. Approximately 85 per cent of the named items of military ammunition and explosives belong in this category. Therefore, rather than list the items, groups I, II, III, and IV are specifically defined and it is assumed that any item not mentioned as belonging to either group II, III, or IV will automatically belong to group I.

Field Storage Group II. All unfused, high-explosive bombs, aircraft mines and torpedoes and fused or unfused fragmentation bombs and fragmentation bomb clusters.

Field Storage Group III. All rockets regardless of filler.

Field Storage Group IV. Chemical fillers, including pyrotechnics and chemical ammunition of all types including gas, smoke and incendiary bombs.

When these categories of ammunition are stored, the storage is accomplished in field storage units.

4. QUANTITY-DISTANCE REGULATIONS

Purpose

The quantity-distance regulations indicate what quantities of various types of ammunition or explosives may be stored within a single ammunition magazine. They also indicate how far various quantities of these various types of ammunition must be located from inhabited buildings, public railways, public highways, and other ammunition magazines. This is accomplished by dividing all items of ammunition into twelve quantity-distance classes. All of the items belonging to one of these quantity-distance classes possess tha same degree of hazard.

Quantity-distance Tables

Figure 8-3 is an example of a quantity-distance table.

The hazards pertaining to particular classes of ammunition or explosives are the characteristics upon which the quantity-distance requirements for that class are based. The relationships between hazards and quantity-distance requirements for certain general classes are as follows:

Fire hazards. Fire is the most common hazard incident to the handling, and storage of ammunition and explosives. Small-arms ammunition, most pyrotechnics, and chemical ammunition for which no tables are shown also are considered fire hazards only as regards quantities and distances. Most other items of ammunition and explosives may, as

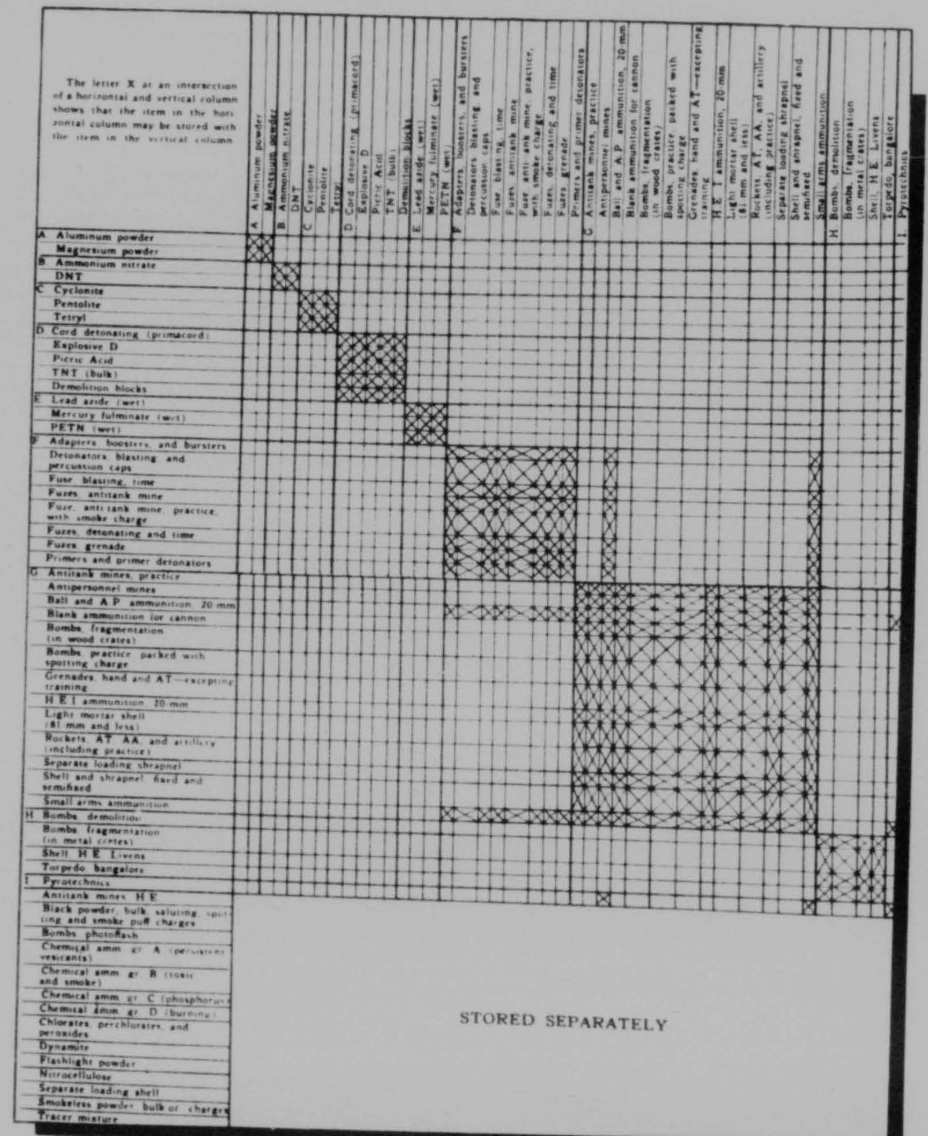

Figure 8—2. Storage Chart for Explosives and Ammunition.

THIS PAGE IS DECLASSIFIED IAW EO 13526

Quantity of explosives		Unbarricaded distance in feet from nearest—

[1] American Table of Distances, requirements for bulk explosives.
[2] Magazine distances conforming with the requirements of paragraph 4: may be authorized under special conditions.
[3] Maximum permitted in any one magazine.

Figure 8–3. Quantity-Distance Table.

a result of fires, detonate and spread disaster to distances considerably in excess of fire-protection distances.

Sympathetic detonations. A sympathetic detonation is one which immediately follows as a direct result of an initial explosion. It may be the result of propagation, or it may be the result of missiles from the initial explosion. In any case, it is an explosion that so closely follows the initial explosion as to be indistinguishable from it.

Magazine-to-magazine Distances. The magazine-to-magazine distances for all classes of ammunition and high explosives are based on New Jersey State law. They are expected to give protection against propagation from explosions in adjoining buildings or magazines. It will be noted that these distances are in all cases substantially less than those required to protect inhabited buildings against structural damage. It is not expected that magazine-to-magazine distances will give protection against structural damage.

Missile Hazards. Explosions involving high-explosive bombs, or loaded-ammunition components introduce a hazard not normally present in commercial explosives. These hazards are missiles which may be projected either as pieces of broken-up bomb cases or other components, or complete bombs. Bombs may, and often do, explode upon impact or as a result of heating in fires. Missile distances prescribed in the quantity-distance tables for classes 3, 4, 5, 6, and 7 are based upon tests made at Aberdeen Proving Ground. They are based upon the distance within which most missiles will fall.

Concussion. The effects of the concussion produced by the detonation of explosives constitutes one of the most common hazards associated with explosives. The distances given in the tables for classes 8, 9, and 10 are expected to give protection against the concussion effect of explosions. They are identical with the American Table of Distances published by the Institute of Makers of Explosives.

Classes and Quantity-distance Tables for Military Explosives and Ammunition. The explosive contents of ammunition or components are shown on drawings, or the appropriate SNL's; if these are not available, the information desired should be requested from the Chief of Ordnance. The quantities shown in the tables herein were computed in the following manner:

a) For pyrotechnics the quantity is the gross weight of the boxes and contents.

b) For bombs the pounds of explosives are computed as follows: If a magazine contained 30,000 bombs, fragmentation, 90LB AN-M-82, the amount of explosives in the magazine is as follows: 30,000 × 13.5 = 405,000 pounds (13.5 is the approximate weight of the high explosives in the bomb).

When military explosives and ammunition are not packed in accordance with the provisions of approved drawings and specifications and SNL's, they will be stored in accordance with special instructions issued by the Chief of Ordnance.

When military explosives and ammunition are packed in accordance with the requirements of approved drawings and specifications and SNL's and are stored in accordance with storage drawings, they are classified as indicated below, and will be stored in accordance with the quantity-distance tables shown.

SMOKELESS POWDER IN CONTAINERS,[1] PYROTECHNICS, OR CHEMICAL AMMUNITION CONTAINING PHOSPHORUS
